Eickemeyer. Coils in series with the armature wound on that part of the pole which is weakened by the armature turns, thus preventing the loss of field necessary for commutation, have been proposed in various forms. In America the Thomson-Houston Company, in 1887, used inclined, or horse-collar, coils round the pole-pieces as near the armature as possible. Coils wound in slots in the pole-pieces have been suggested and used in various ways, but were difficult to arrange, and generally failed because the number of turns necessary could not be got in without diminishing the section of the pole-piece, or causing great leakage; also there was difficulty in ventilating these coils to keep down the temperature. In some plating dynamos of large current, where only a few turns are necessary, they are more successful. So nearly all these devices were abandoned, as good machines with sparkless running and fixed lead could be designed on ordinary lines if due regard were made to getting a strong field with a sufficient number of sections in the commutator.

Max Déri, of Vienna, in working out a combined alternating and direct current machine, thought of the plan of designing a direct-current machine with compensating winding in the pole-pieces, by using a field magnet in the form of a stator of a revolving-field motor, but the armature just as the ordinary direct-current winding. The exciting shunt coils would be wound to form the necessary number of poles, but the compensating winding in series with the armature would be wound in every slot, and would form a winding whose centre would give a pole somewhat backward from that of the shunt winding, thus neutralising the shifting of the field. In an exhaustive paper on the subject Dr. Friedrich Eichberg, of Vienna, gives a complete analysis of the system, and compares the relation

$$\frac{\text{magnet ampere-turns}}{\text{armature ampere-turns}},$$

where he states that in modern machines the proportion is of the value of about 1 to 5, but with special attention to design can the value 1 to 3 be obtained. Dr. Eichberg's analysis of the reactions is very interesting, and worth quoting. He sums up thus:

"(*a*) The flux through the short-circuited coil is

$$F_s = \frac{4\pi}{10} \cdot \frac{N J}{\Sigma m};$$

$\Sigma m$ = total magnetic resistance of the spreading field;
N = number of turns in short-circuited coil;
J = current in short-circuited coil.

In general, neither $\Sigma m$ nor N is a constant quantity, and J depends on the number of turns in the short-circuited winding. For the simplest case of commutation is N and $\Sigma m$ constant, and J assumes, by going through all values from 0 upwards, a positive to an equally large negative value. From this simple case we form the base for the following. The E.M.F. of self-induction or reactance voltage is

$$e_s = \frac{2 F_s \cdot N}{t} \cdot 10^{-8},$$

where = the time of short-circuit. If $b$ = the brush thickness on the circumference of the commutator, and $v$ the peripheral speed of same, $t = \frac{b}{v}$, and therefore

$$e_s = \frac{2 F_s \cdot N \cdot v}{b} \cdot 10^{-8} = 2 \frac{4\pi}{10} \cdot \frac{N^2 \cdot J \cdot v}{\Sigma m \cdot b} \cdot 10^{-8} \quad (A)$$

This E.M.F. is only under the above conditions a constant quantity.

(*b*) We take for the over-compensation an ideal case, that the armature and compensation winding have the same axis which is vertical to the axis of the exciting field. The application to other cases is not difficult.

If $N_c$ and $N_a$ be the total number of conductors in the compensation winding and armature windings respectively, related to the full armature current, $J \cdot 2a$, where $2a$ is the number of armature circuits, the compensation windings obtained from the commutating field is consequently

$$\frac{J \cdot 2a \cdot (N_c - N_a)}{2p},$$

and all windings $N_c - N_a$ operate fully so far as the commutating results in the ideal neutral zone.

$$\frac{N_c - N_a}{2p} = N_0$$

are then the over-compensation turns per pole to the full armature current. $2a \cdot N_0 = n_0$ is the number of over-compensation turns per pole related to the current J. The cross-section of the commutating field is $b \cdot l$, where $b$ again represents the brush thickness related to the armature circumference and $l$ the length of the armature.

If $B_c$ represents the flux of the commutating field, then we have the equation

$$b \cdot l \cdot B_c = \frac{4\pi}{10} \cdot \frac{n_0 \times J}{\Sigma M} \quad . \quad . \quad . \quad (B_1)$$

Digitized by Google

$\Sigma M_c$ is the magnetic resistance of the commutating field at the armature circumference of the brush breadth, $b$, and armature length, $l$. The E.M.F. induced through the movement of the short-circuited coil is

$$e_1 = B_c \cdot l \cdot v \cdot N \cdot 10^{-8} \quad . \quad . \quad . \quad (B_2)$$

If we now introduce $(B_1)$ and $(B_2)$ we get

$$e_i = \frac{4\pi}{10} \cdot \frac{n_0 \cdot J}{\Sigma M_c} \cdot \frac{1}{b \cdot l} \cdot l \cdot v \cdot N \cdot 10^{-8}$$

or,

$$e_i = \frac{4\pi}{10} \cdot \frac{n_0 \cdot J \cdot v \cdot N \cdot 10^{-8}}{b\,(\Sigma M_c)} \quad . \quad . \quad . \quad (B)$$

This is also an E.M.F. of constant quantity, and is, therefore, capable of annulling the reactance voltage. If we take the equation A = B we get

$$2 \cdot \frac{4\pi}{10} \cdot \frac{N^2 \cdot J \cdot v \cdot 10^{-8}}{(\Sigma m) \cdot b} = \frac{4\pi}{10} \cdot \frac{n_0 \cdot J \cdot v \cdot N \cdot 10^{-8}}{b\,(\Sigma M_c)}.$$

Shortening this we get

$$\frac{2N}{n_0} = \frac{\Sigma m}{\Sigma M_c}, \text{ or } \frac{n_0}{N} = \frac{2 \cdot (\Sigma M_c)}{\Sigma m} \quad . \quad . \quad . \quad (C)$$

which means that the number of compensation turns per pole is in proportion to the number of ampere-turns in the short-circuited coil, as twice the magnetic resistance of the commutation field is in proportion to the magnetic resistance of the field which produces the reactance voltage. It is equally important as interesting that this relation is completely independent of the magnitude of the current to be commutated and the peripheral velocity of the armature. For the case of a commutation field equally strong in all places (therefore homogeneous), which does not exist in practice, but can be thought of in theory, we could divide both sides of equation (C) by $\frac{d\pi}{2p \cdot b}$, and get

$$\frac{\frac{n_0}{N \cdot d\pi}}{2p \cdot b} = \frac{\frac{2 \cdot (\Sigma M_c)}{d\pi} b \cdot 2p}{\Sigma m}.$$

The denominator on the left side then means that the number of armature turns related to the current J per pole, we will call $n_a = \frac{N \cdot d\pi}{b}$.

The expression $\frac{\Sigma M_c}{d\pi} b \cdot 2p$ represents the magnitude of the magnetic resistance of the main field (which is above mentioned as being homogeneous). We will call $\Sigma M$. Then is

$$\frac{n_0}{n_a} = 2 \cdot \frac{\Sigma M}{\Sigma m}.$$

That is, for this case the proportion of the over-compensation turns per pole to the armature turns per pole equals the proportion of twice the magnetic resistance of the main (total) field to the magnetic resistance of the field produced by the reactance voltage.

If we put $n_0 = n_c - n_a$, then

$$\frac{n_c - n_a}{n_a} = \frac{2 \cdot (\Sigma M)}{(\Sigma m)}; \text{ or } \frac{n_c}{n_a} = \frac{2 \cdot (\Sigma M) + (\Sigma m)}{\Sigma m}.$$

Since

$$\frac{n_c}{n_a} = \frac{N_c}{N_a},$$

so we get

$$\frac{N_c}{N_a} = \frac{2 \Sigma M + \Sigma m}{\Sigma m} \quad . \quad . \quad . \quad . \quad . \quad (D)$$

This proportion $\frac{N_c}{N_a}$ is at the same time the proportion of the copper in the compensation turns to the copper in the armature turns, which, therefore, substantially depends on the magnetic disposition of the machine."

Prof. Ryan, to whom we owe much for the investigation into armature reaction, proposed to wind these compensation coils in slots in the pole-pieces, using an ordinary radial-pole field magnet, so that every element of the armature winding could find a corresponding opposing element in the pole-piece, thus completely neutralising the armature effect on the field. Ryan also added a pole on the point of commutation to provide a reversing field, and thus enabled a very large overload to be got out of the machine with a fixed point of commutation. This method is probably the most successful in the use of windings in slots on the pole-pieces.

Various modifications of the slotted pole windings have been proposed and used with more or less success. Dynamos for very high speeds have been made by Messrs. Brown, Boveri, and Co., of Baden, who have sent me photographs of their machines. They are wound on the Déri plan. The best results have been obtained with the shunt separately excited—they run at 3,000 to 3,500 revolutions per minute with fixed brushes. The shunt coils

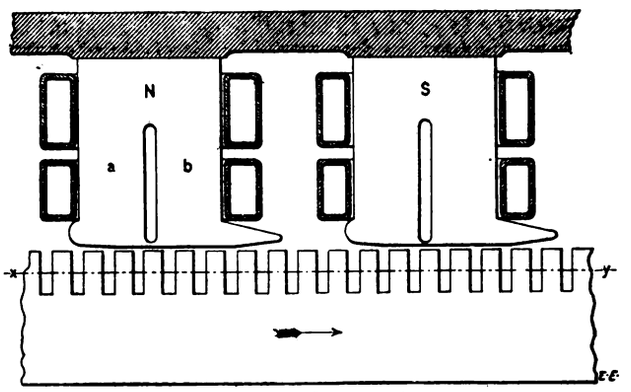

FIG. 4.—Development of 50-kw. Lundell Generator.

are not spread in the slots, but wound across several slots to form a two or four pole field as desired; one tooth between the shunt windings serves as a reversing pole. All makers of turbo-generators of the direct-current type use similar methods—the Austrian Union Company, Oerlikon Company, Parsons and Co., amongst others. Sautter, Harlé, and Co., of Paris, use an ordinary four-pole field with reversing poles of considerable size between the usual poles. Although these additional poles must cause considerable leakage, yet it is a question whether this is not the cheapest form of field, and it certainly can be made effective; motors are being made by this method, and stand considerable overloading and reversal of direction of rotation without sparking.

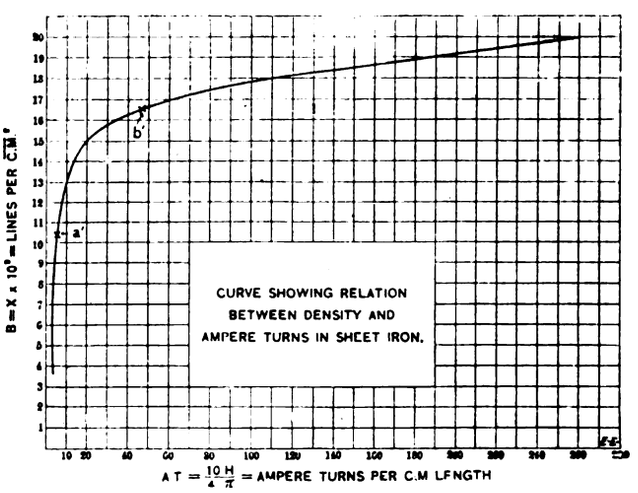

FIG. 4A.—Sheet-Iron Magnetisation Curve.

This is especially useful for motors with intermittent loads, and where reversal of the direction of rotation is required, such as for lifts, cranes, cogging mills, etc. For ordinary motors, with longer constant loads, heating will come in before the large load, so that ordinary methods suffice, and very high speeds are not necessary in motors, except in some rare case for centrifugal fans and pumps, which can be treated as special.

A very successful means of securing a fixed lead of the brushes is found in the machine designed by Mr. Lundell (Fig. 4). The pole is slotted radially into two equal parts, but the forward part has the pole-piece extended, so that this half, having an air-gap of lower reluctance than the other half,

Digitized by Google

has at no load the greater number of lines of induction passing through it. By this means it is at a high saturation point, but as the load is put on the armature the excitation is increased either by series winding or by increasing the shunt current. This increased excitation then affects the

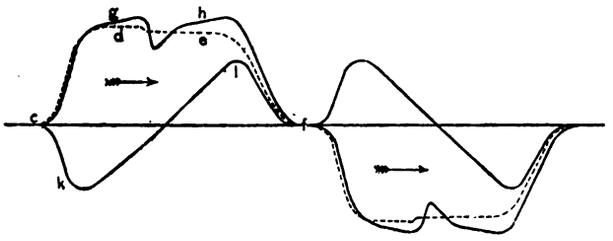

FIG. 5.—Calculated Pole-Face Induction.

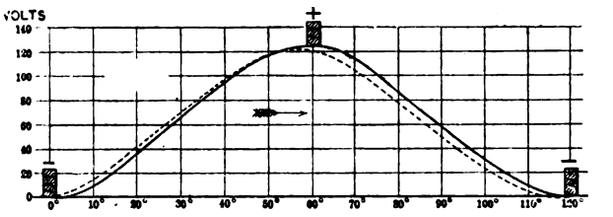
back part of the pole-piece, because being less saturated than the forward part, in spite of its greater air-gap reluctance, its permeability makes its total reluctance less Thus the zone of the commutating space is kept constant, and no change in lead is necessary for change of load.



IG. 6.—Distribution of Potential around Commutator.

The diagram (Fig. 4A) shows a magnetisation curve. The back part of the magnet core is worked on the part of the curve marked $a^1$ and the front part at $b^1$, the knee of the curve being avoided. Fig. 5 shows the resultant curves due to armature and field at no load, and Fig. 6 the curves of potential at the brushes, where the movement of the

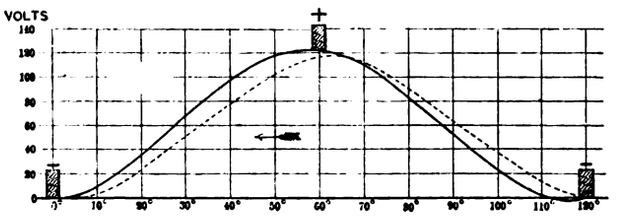


FIG. 6A.—Distribution of Potential around Commutator, Generator running in wrong direction.

necessary commutating field is so small as to give constant lead. In this form of magnet the values of the induction used are in lines per square inch: pole-face, 55,000 to 59,000; pole-core, 85,000 to 90,000; yoke, 80,000 to 85,000; armature core, 85,000 to 90,000; armature teeth, 130,000 to 140,000. There is no loss of efficiency in this

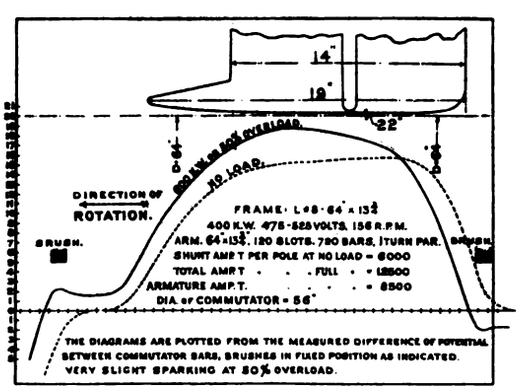

FIG. 7.

method, but an actual gain, as the polar arc can be made as much as 78 per cent. of the polar pitch, thus keeping down the gap reluctance.

Satisfactory machines have been made of dimensions much smaller than the ordinary sizes for the output and speed, such as 125 kw., 450 revolutions, with the armature 26½in. diameter, 9½in. long, which would be about 39in. by 8in. in ordinary practice; 400 kw. at 400 revolutions, armature 44in. diameter, 11½in. long; 420 kw. at 320 revolutions, 52in. diameter, 11½in. long; 400 kw. at 156 revolutions, 64in. diameter, 13¾in. long. A diagram of the latter dynamo is shown in Fig. 7. The curve on dotted lines gives an accurate idea of the flux distribution through the armature teeth and the armature conductors at no load. The conformation or shape of this curve is wholly dependent on the flux from the poles, as there are no disturbing currents in the armature conductors. The curve in full lines represents the resultant flux through the teeth, and the armature conductors at 50 per cent. overload = 600 kw. This flux is dependent upon the flux from the poles and upon the disturbing influence of the currents in the armature conductors. The latter are causing a cross magnetising and a demagnetising effect on the flux from the poles as well as a disturbance (extra flux) in the teeth at or near the points of commutation, as clearly shown by the peculiarity of the curve at these points. The development of the pole-face on a straight line shows the air-gap to be ·22in. in the centre of the pole. The curves are plotted from the measured differences of potential between commutator bars. The small distortion at 50 per cent. overload considering the large armature reaction, which amounts to 12,750 ampere-turns per pole, shows the value of the principle, which is very satisfactory for dynamos, or motors which run in one direction only, at ordinary speeds. Whether the principle could be used for dynamos at the speeds used for steam-turbines has not yet been tried, but by careful design the difficulties might be overcome.

## FORTHCOMING EVENTS.

FRIDAY, MAY 26.

**Institution of Electrical Engineers.**—At 5 p.m., annual general meeting.

**Physical Society.**—At 3.30 p.m. (National Physical Laboratory, Bushy House) the following demonstrations will be given: (1) "The Specific Heat of Iron at High Temperatures," by Dr. Harker; (2) "The Measurement of Small Inductances," by Mr. Campbell; and (3) "Two New Optical Benches," by Mr. Selby.

**Royal Institution.**—At 9 p.m., "The Development of Spectro-Chemistry," by Prof. J. W. Brühl.

SATURDAY, MAY 27.

**City and Mechanical Engineers' Society.**—At 2 p.m., visit to Messrs. D. Napier and Son's motor works, Acton Vale.

**Electrical Engineers (R.E.V.).**—Exhibition of corps work at headquarters.

TUESDAY, MAY 30.

**Optical Convention.**—At 8 p.m., opening ceremony (Northampton Institute).

THURSDAY, JUNE 1.

**Royal Institution.**—At 5 p.m., "Electromagnetic Waves," by Prof. J. A. Fleming (Tyndall Lecture II.).

**Chemical Society.**—At 8 p.m., general meeting.

**Incorporated Municipal Electrical Association.**—June 27-30, annual convention.

## NEW COMPANIES REGISTERED.

**S. M. H. Tramway Syndicate, Limited.**—Capital, £1,000. Object: to apply for powers to construct light railways or tramways in Durham, to equip, maintain, and work the same by means of electrical or other power, etc. Registered office: 13, St. Helens-place, E.C.

**Kerry Electric Supply Company, Limited.**—Capital, £2,000; and without articles of association, for the purpose of acquiring and taking over as a going concern the business of generating and supplying electric light and electric energy now carried on by the Killarney Electric Lighting Company, Limited, at Killarney, county Kerry. Registered office: Killarney, co. Kerry.

### Lien Registered.

**Auto-Electric Rifle and Target Company, Limited.**—Lien registered May 11 for £100 7 per cent. debentures, part of £5,000; amount previously issued, £2 800; no trustees; charged on the undertaking and all the property, present and future.

### Lien Discharged.

**National Electric Construction Company, Limited.**—Discharge registered May 12 of mortgage dated Aug. 4, 1904, for £20,000.

## THE LONDON POWER BILLS.

The Select Committee of the House of Lords under the chairmanship of the Earl of Camperdown completed their consideration of the London Power Bills on Tuesday last, and reported certain of these Bills to Parliament. Amongst the eight or nine applicants for powers for the supply of electricity in bulk appearing before the committee the most successful has been the Administrative County of London and District Electric Power Company. In our issue for March 24 this year we published a map of the very large area over which this company wish to supply. The committee have passed its application for rights over the whole of the eastern portion of this area, which was termed the industrial area. A small exception is made in the case of Stoke Newington, which has been given to the North Metropolitan Power Company. It has also secured the right to supply in bulk to authorised distributors in all that portion in the west of London which lies to the south of the River Thames. Approximately it may be said that the County of London and District Electric Power Company has secured about seven-eighths of the area applied for. The Metropolitan Electric Supply Company have been granted by the committee that portion of the western non-industrial area which lies to the north of the river. The committee have in passing these Bills forward to Parliament inserted clauses which more or less protect existing undertakers. The chief provisions drafted to secure this object are to be found in Clauses 48 and 48A, which are reproduced elsewhere in this issue. The companies which have already the power to supply electric energy within the area affected have not agreed to these clauses, and distinctly stated through their counsel that they could only be efficiently protected by the striking out of their areas from the Bill. Under Clause 48A the onus is left with the Board of Trade to determine when competition between existing undertakers and the power company shall be allowed, and the terms and conditions which shall be adopted for the protection of the present distributors. The sections of this clause are worthy of careful perusal. Thus it is clear from the first section that the cost to the consumer of electrical energy for power purposes is to be the ruling factor which is to influence the Board of Trade in allowing the new company to come into any area. It was ably argued by Mr. J. D. Fitzgerald that one method of protecting existing undertakers would be to insist that if the power company were to supply the manufacturer direct at certain schedule prices they must also give, if required, a supply in bulk to the authorised distributor at such a price that he would be able to compete at these rates. Under Clause 3 the power company can be prevented from cutting rates in any one district in order to get the consent of the Board of Trade to supply, and then increasing the rates when they have ousted the present undertakers. It is true that under this clause the Board of Trade is empowered to give their consent to an increase in charges, but as they would have the whole facts before them they could prevent preferential rates being given to any district. Under Clause 4 the new company would have to give a supply wherever demanded, and hence would be prevented from picking and choosing which consumers they would supply and which consumers it would not pay them to reach. Under Clause 5 the company can be compelled to lay mains in certain streets within a reasonable time. In another clause elsewhere in the Bill it is further provided that "if the company do not within the prescribed period comply with such requirements, the Board of Trade may order that the powers of the company to distribute energy within such area shall cease." The general effect of the two clauses in question, if the

Digitized by Google

Bill eventually survives the strenuous opposition which it will meet in the House of Commons, will be to grant very great discretionary powers to the Board of Trade In fact, before the power company commence operations on a large scale, they would need to convince the Board of Trade on the very matters which the committee have been hearing evidence for the last two months. The ultimate good which a cheap supply of electric power would confer on Greater London cannot be too strongly insisted on, and this will be duly recognised by the Board of Trade. When it comes, however, to competition with undertakers who are handicapped by the fact that they have had to bear heavy pioneering costs, it is exceedingly difficult to reconcile conflicting interests. It seems to us, however, that provided the power supply company are forced to give existing undertakers a bulk supply at such rates that they can afford to throw out of service their existing plant and still pay out of profits the capital charges on the same, then consent should be given. There is no doubt that the success of power distribution on the Tyne under the engineering skill of Mr. C. H. Merz has led to the committee's decision, and this gentleman is to be congratulated on having convinced the Select Committee of the feasibility of his scheme for London. Whichever way the decision of Parliament may go, the result of the fight is bound to be a cheaper supply of electrical energy throughout the London areas. If the Bills pass, the fears of competition will force the present undertakers to reduce prices, and should the opposition succeed in throwing out the Bills this year, they must also reduce rates to remove the temptation for the promoters to try again next session.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### LIGHTNING.

SIR,—Your suggestion that a committee should be formed to collect and consider particulars of the working of lightning arresters is a good one, but why make it a committee of electrical engineers? Why not follow closely the Lightning Research Committee, and select principally members who are not known as experts on the subject? The result might then be as productive of surprising results as the report just issued, especially if the particulars to be considered were also mostly by non-experts. This report is valuable, inasmuch as it provides a ready excuse for any lightning conductor system that may fail, for blame can be put entirely on lightning and not on the man who made a mistake in the application of the system. Moreover, it will be impossible to prove whether the system was applied in accordance with the committee's recommendations or not, since this report is so contradictory that it may be read in any way one likes. So far as it is good it is not new, and so far as it is new it is not good. It is not probable that experts will regard it as the acme of wisdom on the subject.

It is impossible in the necessarily limited space available for a letter to do more than point out two or three of its peculiarities. The fact that Sir Oliver Lodge's preface is at variance with the report that follows is, perhaps, scarcely a matter for surprise, but I may point out that while it is insisted upon that the only means of securing protection is to adopt the complete birdcage system, it is suggested that where heavy expense is not justified two or more conductors might be erected in the ordinary manner, connected by a horizontal conductor, and the metal work of roof and rainfall pipes connected and "earthed." For a tower, spire, or chimney shaft two conductors are recommended. Now, neither of these form a cage system. Are we to suppose that the committee are recommending what they believe will not be effective?

The cage system is not new. It may be said to date back to Faraday, and is undoubtedly the most perfect system of protection, because, when, it is adopted, there is no necessity for the careful consideration that an expert finds it necessary to bestow on a case. All that is required is to apply the system in its entirety, and no heed need be taken of alternative paths or complications of metals in the building. It is essentially the novices' method of protection, but I presume that no one would urge seriously that the bastard cage system that the committee may be presumed to recommend would be equally effective. Was it not tried by Melsens, and failed?

The true birdcage system would be prohibitive in cost in most cases where it was possible of application, and no electric light leads or telephone wires could be taken into the buildings, since they could not be connected; while in many cases, such as buildings not entirely detached, it would be impossible of application.

As regards joints, the committee may be presumed to confirming and even accentuating the necessity for connections that will show no resistances, yet they appear to consider the resistance of joints so unimportant that they do not advise their being tested when the "earths" are tested.

That the report is not more satisfactory is not to be wondered at considering the very meagre, and in some cases absolutely incorrect, particulars of the cases that were sent by reporters. The committee (or one of its members) appears to have been trying ever since its inception to disturb public confidence in the efficacy of conductors, either to justify its existence or for another purpose that is probably obvious. Much has been made in (possibly inspired) newspaper paragraphs of the fact that the committee received reports of 125 cases of damage by lightning in the three years, out of which 40 were to buildings that were supposed to have been efficiently protected. That my statement is warranted is, I think, shown by the fact that the committee states it deems it unnecessary to go into details of the "unprotected" cases, but appends a selection from the list of "protected" ones, and then gives details of 34, out of which 26 only are justifiably placed in this list. What the 16 cases not specified were we are, I suppose, not permitted to know, but we may presume they are on a par with the detailed account, sent to the committee by one of its members, of damage by lightning to the Houses of Parliament that did not occur!

It would be absurd for me to hazard a guess as to the number of cloud-to-earth lightning discharges that occur in this country every year. Suffice it to say that the number is enormous, and since very lofty structures are admittedly somewhat more exposed to be struck than low ones, and the majority of very lofty ones are provided with lightning conductors, it is reasonable to suppose that if the committee's wholesale condemnation was justified, an alarming number of lightning conductor failures would be reported annually. Now, what are the actual figures?

I can state from a close investigation into the subject, extending over the past 17 years, that from 300 to 400 buildings are damaged by lightning in this country every year, out of which less than a dozen a year had conductors, and these had mostly been in existence for periods ranging from 20 to 60 years, had been fitted by plumbers, ironmongers, builders, and others whose trades did not imply that they were experts, and would have been condemned as inefficient before the accidents by anyone with the faintest pretence to knowledge of the subject. Is a lightning conductor to be regarded as the only contrivance on earth that must be efficient for half a century without attention or repair, and irrespective of whether it was properly applied in the first instance or not.

And what about the cases in which conductors have been struck and have not failed? It may not be generally known that there are usually signs by which one can tell whether a conductor has been struck or not, and that it is quite a common thing to come across those signs I have in my possession three examples, and might have made a large collection but that I did not until comparatively recently think they were of interest. It is not easy, also, to get them because the owners generally like to keep them as curiosities, or say that, as they have answered so well, they will not have them disturbed.

Digitized by Google

When the Lightning Rod Conference—which meant well, and only failed through being too brief—commenced its labours, it enquired into the method employed by experts, adopted what was good and rejected what appeared bad. It also made a point of acquiring all the information on the subject that was available. Had the recent committee adopted the same plan, I venture to think it would not have stated that a tube such as it appears to recommend gives as much effective area as the earth-plate recommended by the conference. But does the committee recommend this? And is the tube to be driven a distance of 30ft. below water-level? If so, why add the trickle from the rain-pipe?

Tubular earths were recommended by Spang in America nearly 40 years ago, and I believe they were extensively used there, and yet we hear that lightning conductors have got into disrepute among our Transatlantic cousins owing to the number of failures that have occurred there. They were also used in this country some 20 to 30 years ago, but proved unsatisfactory.—Yours, etc., ALFRED HANDS.

## INDUCTION MOTORS.

SIR,—With regard to the excellent articles by Mr. Rogers on the induction motor, there are one or two points which he leaves somewhat obscure. For instance, the use of the letters R and C on p. 663; is R reactance or resistance, and is C resistance or reactance? This part of his paper is not quite clear to the direct-current man. To fix ideas would Mr. Rogers show some method of simply calculating the following?

A choking coil on a 500-volt circuit takes six amperes but only 2,000 watts; another choking coil on the same circuit takes four amperes 1,600 watts. What current do they take (1) when in series, (2) when in parallel? How do the formulæ given apply?

Lastly, how is the magnetising current got at no load? Suppose the current at no load three amperes on a 200-volt machine, and cos $\phi = \cdot 5$. Can we assume the component at right angles to be the magnetising current and neglect leakage?

I put forward these points as they are generally very obscurely put in text-books, not to say contradictory.—Yours, etc., STUDENT.

## THE LACK OF ADAPTATION IN BRITISH TRADE METHODS.

BY SIMPLEX.

Technology and commercial organisation are so intimately blended in the upbuilding of an engineering firm, that we think no apology is needed for the introduction of such a subject as the present into the pages of a journal devoted to the interests of British electrical engineering. The immediate cause of this note was a conversation which we have had with a gentleman who, though not an Englishman, has for years identified himself with British manufacture, and who by extensive travel in former years has obtained the necessary qualifications to give an opinion of the methods of British engineering trading from an entirely detached point of view. Though we are aware that friendly advice from a stranger within our gates is not always unbiassed by ulterior motives, we are convinced that the remarks which we here record are worthy of serious consideration.

This gentleman, before visiting England, had some experience with British commerce in the Far East, receiving at various times consignments of goods—some of them fragile instruments—packed in such a way that they were either badly broken in transit or damaged by water and rough usage on arrival at ports not always adapted, either in cranage appliances, wharf storage, or the highest class of labour, for the accommodation of delicate goods unless most carefully packed. His experience was that when a British firm was remonstrated with as to the unsuitable manner in which the goods were packed, having regard to the prevailing conditions, a letter of disclaimer for all damage done was received in return, the firm probably stating that the "goods were dispatched in good condition from our works, being carefully packed in a manner which we have found to be sufficient for all reasonable usage." Very possibly: but in some parts of the world "reasonable usage" is too expensive a luxury to be attainable. Such treatment was contrasted with methods of packing adopted by German and American firms: an instance concerning the former country being quoted where the interior of the case was heavily lined, first with sheet zinc, and then with a specially prepared felt impregnated with bitumen, to preserve the goods from water, while a package was received from America consisting of one case within the other, the inner being supported on all sides from the outer by spiral springs, reducing to a minimum the danger of shock to the contained apparatus. These examples illustrate the difference in care in adapting their methods to special conditions displayed by British and foreign firms.

Another point raised was that British manufacturers were inflexible as to the quality of goods supplied to a foreign market. The German custom is to send out a series of qualities of any manufacture which they wish to introduce to a reliable agent, asking him to feel the pulse of the market as to which quality best suits the conditions. Upon his report being received, the manufacturer lays himself out to make that quality. It is clearly understood, both by the maker and buyer, that the goods may not be the best obtainable, but so long as they suit the market they will be supplied in sufficient quantity to meet the demand. In every probability the introduction of a cheap line will lead to the demand for a better quality, enabling the firm to increase its business. The British manufacturer will have nothing of this sort. He makes one grade of goods, and if they do not suit the market he deplores the bad taste of the buyer.

The British manufacturer is slow to understand that at various corners of the world there are other languages besides English. When an Englishmen sends a tender to a French, German, or Russian firm, he sends it in English. When a Frenchman quotes a Russian for any goods, he takes care that language and prices are Russian. As a case in point, our critic instanced the fact recently made public in our newspapers that the German Consul-General in Shanghai has recently written home saying that, as a result of the present war, North China will shortly be much more widely open to trade than in the past, Canton, Hankow, and Tchungking possibly developing into rivalry with Shanghai and Hong-Kong. And this German official, with an intelligent anticipation of events, offers the German Consulate building, the support of commercial experts attached to the Consulate, and competent instructors, in order that German commercial men may learn to speak the language of that Celestial Empire. This forward policy of dealing directly with the Chinese was contrasted by our friend with the condition of things in Hong-Kong. Our informant stated that this British colony, though now the second port in the world, is almost entirely dependant for its prosperity on its shipping interests. The bulk of the profit in trading goes to the Chinese middleman who can talk pidgin English, because the Englishman is apparently unable to speak enough Chinese to get into contact with the actual native buyer or seller.

To take a case nearer home, the undoubted influence exercised by the German Government on that of the Ottoman Empire on behalf of Messrs Krupp in the recent purchase of guns, shows how well recognised is the relation between engineering and national prosperity in Germany. What likelihood is there of official Britain taking so strong a manufacturing step? It is holding the wrong end of the stick to say that if the British Government would similarly support the manufacturer our industries would grow. The Government would like to see something to support; industry and intelligent enterprise must first be shown, and direct pressure brought to bear. The direct advantage to be gained must be demonstrated by the manufacturers before the Government would commit itself to such grave proceedings. Our somnolent firms must be prepared to dance before the Government will consider the question of piping.

So much for our foreign trade methods. Since his residence in England our critic has studied the organisa-

Digitized by Google

tion of our firms and educational agencies, and is surprised at the want of correlation between the training system in school and shop. In his words: "You English are essentially a brilliant race of engineers, but you are too stubborn. Your established methods have met former conditions successfully, and you do not see that old landmarks are giving way to new ones." For example, the new engineer must be equally efficiently trained in science, commerce, and industry. But, according to our friend, the educated Englishman hates to dirty his hands. For an ordinary railway journey the clerk buys a second-class season ticket to differentiate himself from the artisan who is travelling with a workman's ticket. Yet the clerk with his nice clothes is, owing to the law of supply and demand, probably getting 25s. a week; the navvy is perhaps earning 7d. an hour for 56 hours a week, time and a quarter for every extra two hours per day, time and a half after that, and double time on Sunday and Bank holidays! As a contrast to that, the German workman will spend some years in a technical school with the single purpose of becoming an intelligent artisan, the result being that a German mechanic is perhaps the best man of any operative in the world to be sent away to erect plant without special technical supervision. Again, an English firm when touting for orders usually sends out a traveller whose commercial instinct far outstrips his engineering knowledge. German firms organise departments of "commercial engineers," whose functions are both to drive bargains and talk intelligent shop

Our foreign critic concluded with the statement: "British trade will flourish. There is no fear that the stamina of the Englishman will desert him when face to face with difficulty. But my association with an English firm causes me to regret very sincerely that so much of the Englishman's difficulty is of his own making."

Is it true, then, that we are "impossible"?

## REPORTING ACCIDENTS IN CONNECTION WITH ELECTRIC LIGHTING.

BY A BARRISTER.

Section 38 of the Electric Lighting (Clauses) Act, 1899, enacts that the undertakers shall send to the Board of Trade notice of any accident by explosion or fire, and also of any other accident of such kind as to have caused, or be likely to have caused, loss of life or personal injury which has occurred in any part of the undertakers' works or their circuits, or in connection with those works or circuits, and also notice of any loss of life or personal injury occasioned by any such accident. The notice must be sent by the earliest practicable post after the accident occurs, or, as the case be, after the loss of life or personal injury becomes known to the undertakers. If the undertakers fail to comply with these provisions, they are liable for each default to a penalty not exceeding £20. The Board of Trade may also, if they deem it necessary, appoint any electric inspector or other fit person to enquire and report as to the cause of any accident affecting the safety of the public which may have been occasioned by or in connection with the undertakers' works, whether notice of the accident has or has not been received from the undertakers, or as to the manner and extent in and to which the provisions of the special order and the principal Act and of the Board of Trade regulations, so far as those provisions affect the safety of the public, have been complied with by the undertakers; and any person appointed under this section, not being an electric inspector, shall, for the purposes of his appointment, have all the powers of an electric inspector under the special order.

There is also another Act which requires notice of any accident to be sent to the Board of Trade in the case of certain employments, and that is the Notice of Accidents Act, 1894. Section 1 of this Act provides that where there occurs in any employment to which this section applies any accident which causes to any person employed therein either loss of life or such bodily injury as to prevent him on any one of the three working days next after the occurrence of the accident from being employed for five hours on his ordinary work, his employer shall, as soon as possible, and in case of an accident not resulting in death, not later than six days after the occurrence of the accident, send to the Board of Trade notice in writing of the accident, specifying the time and place of the occurrence, its probable cause, the name and residence of any person killed or injured, the work on which any such person was employed at the time of the accident, and in the case of an injury the nature of the injury. If any person wilfully makes default in complying with the requirements of this section, he is liable on summary conviction to a fine not exceeding 40s. For the purposes of this section the expression "working day" shall mean a day on which the person injured would, but for the injury, be employed in his ordinary work. The employments to which this section applies are "construction, use, working, or repair of any railway, tramroad, tramway, gasworks, canal, bridge, tunnel, harbour, dock, port, pier, quay, or other work authorised by any local or personal Act of Parliament; construction or repair by means of a scaffolding of any building which exceeds 30ft. in height, or use or working of any such building in which more than 20 persons, not being domestic servants, are employed for wages; use or working of any traction engine or other engine or machine worked by steam in the open air." And by Section 2 of the Act of 1894, if the Board of Trade are of opinion that any other employment in which 20 persons or more, not being domestic servants, are employed by the same employer is specially dangerous to life or limb, the Board may, by order, direct that Section 1 of this Act shall apply to that employment.

Rule 15 of the Board of Trade regulations made under the Electric Lighting Acts, 1882 and 1888, provides that "where any accident by explosion or fire, or any other accident of such kind as to have caused or to be likely to have caused loss of life or personal injury has occurred at any part of any electric line or work, the undertakers shall give immediate notice thereof to the Board of Trade." And Rule 47 provides that "if the undertakers make default in complying with any of the preceding regulations, they shall on conviction be liable to a penalty not exceeding £10 for every such default, and to a daily penalty not exceeding £10. The recovery of a penalty under these regulations shall not affect the liability of the undertakers to make compensation in respect of any damage or injury which may be caused by reason of the default."

Works for generating or transforming electricity come within the Factory and Workshop Act, 1901. Section 149 of that Act, in conjunction with the sixth schedule, Sub-Section 20, classes amongst "non-textile factories," "'electrical stations'; that is to say, any premises or that part of any premises in which electrical energy is generated or transformed for the purpose of supply by way of trade or for the lighting of any street, public place or public building, or of any hotel, or of any railway, mine, or other industrial undertaking." Electric accumulator works have been certified by the Secretary of State to be dangerous or injurious to health. The following special regulations have been issued for such works:

*Duties of Occupiers.*—They shall provide bath and lavatory accommodation with a plentiful supply of hot and cold water, soap, nail-brushes, and towels. They shall provide respirators and overall suits for all persons employed in the operation of mixing. They shall provide gloves and aprons for all persons employed in the occupation of rubbing. They shall see that the gloves are constantly inspected and renewed when defective.

*Duties of Persons Employed.*—In cases where the co-operation of the workers is required for carrying out the foregoing rules, and where such co-operation is not given, the workers shall be held liable in accordance with the Factory and Workshop Act, 1891, Section 9. A good respirator is a cambric bag, with or without a thin flexible wire made to fit over the nose.

It appears from the report of the chief inspector of factories and workshops for the year 1901, that the Dangerous Trades Committee have submitted certain recommendations as regards electrical works, which will be

Digitized by Google

found at pp. 28-30 of their report. The following is an extract from the report (p 28):

"*Electrical Stations.*—These important works continue, and will continue, to increase in number and size, especially now that it is made clear by the new Act that any place in which electrical energy is generated or transformed (except private houses) is a factory, and as such under the regulations of Factory Acts. The way to supervision has been paved by calling attention of occupiers and managers to the recommendations of the Dangerous Trades Committee on electrical works, and I annex a report by Mr. Fearon showing how far the recommendations are already generally observed, the difficulties as to others, and making additional recommendations. It is only necessary to add to his report that it is of little use having a card of instructions as to artificial respiration hung up in the works unless the engineers and employés sometimes practice the rules given, so as to know what to do when occasion requires without reference to the card."

One effect of putting electrical stations as above defined within the Factory and Workshop Act, 1901, is to require notice of accidents causing death or bodily injury within the meaning of Section 19 to be given to the inspector for the district. The above provisions are independent of the notice to the Board of Trade of accidents and enquiries into the same provided for by Section 38 of the schedule to the Electric Lighting (Clauses) Act, 1899, previously referred to. The latter section covers a wider field than the former.

Section 19 of the Factory and Workshop Act, 1901, provides (1) that where there occurs in a factory or workshop any accident which either (*a*) causes loss of life to a person employed in the factory or workshops, or (*b*) causes to a person employed in the factory or workshop such bodily injury as to prevent him on any one of the three working days next after the occurrence of the accident from being employed for five hours on his ordinary work, written notice shall forthwith be sent to the inspector for the district; (2) if the accident causes loss of life, or is produced either by machinery moved by steam, water, or other mechanical power . . . notice shall forthwith be sent to the certifying surgeon for the district. The notice shall state the residence of the person killed or injured, and the place to which he has been removed. The penalty for not giving the proper notices is a fine not exceeding £5.

Sub-Section 1 (*b*) is similar to part of Section 1 (1) of the Notice of Accidents Act, 1894, referred to earlier. That Act, however, does not apply to factories or workshops, but only applies to certain employments specified in the Act. It would seem from the Factory Act that every "bodily injury" caused by an "accident" which prevents a person from being employed during the statutory period must be reported, no matter how the injury arose.

## LONDON ELECTRIC POWER BILLS.

As announced briefly in our issue of last week, the Committee of the House of Lords struck out a number of Power Bills on Thursday, 18th inst. The two principal survivors are the Administrative County of London and District Company and the Metropolitan Electric Supply Company. It was decided that the latter company should take those portions of the non-industrial areas to the west of London over which they sought powers, and that these should be omitted from the Administrative County of London area

These two Bills were reconsidered by the committee on Monday last, after the parties interested had had an opportunity to formulate reasonable suggestions to obviate the hardship that, in the opinion of the committee, must arise from the entry of a new power company into an area in which the undertaking of a company was subject to purchase by the local authority.

Mr. BALFOUR BROWNE, K.C, who appeared for the various companies, said the consideration his clients had given to the subject induced them to believe that there was no way to obviate the hardship but by leaving out of the Administrative Bill those districts in which existing companies were under statutory powers of purchase.

Mr. RAM, K.C., on behalf of the Metropolitan Electric Supply Company, said they had decided to omit Kensington from their area, as this was the only district in which a company had power to supply, but they reserved the right to carry mains through the area.

Mr. FITZGERALD, K.C. (for the Administrative County of London Company), said that with regard to outside districts to the west of London, like Teddington, Twickenham, and Isleworth, his company was not opposed by the existing supply companies. He submitted two clauses to the committee which, he contended, would meet the hardships complained of, and which were, after discussion, accepted by the committee. The first was Clause 48 of the Bill, which was amended to read as follows:

"48. The powers of the company for the supply of energy shall be subject to the following provisions:

"1. Energy shall be supplied under this Act only (*a*) for supply to authorised undertakers, and (*b*) for providing power to any person.

"2. The energy supplied to authorised undertakers may be used by them for lighting or other purposes, and the energy supplied to any person for power may be used by such person for lighting any premises on any part of which the power is utilised, but save as aforesaid the company shall not supply energy for lighting purposes. Provided that where energy is supplied to any person for power within the area of supply of any authorised distributors the energy used by such person for such lighting purposes shall not in any year, except with the consent in writing of the authorised distributors, exceed 20 per cent. of the total amount of energy supplied to such person, and save as aforesaid the company shall not supply energy for lighting purposes.

"3. Energy shall not be supplied under this Act by the company (except to authorised undertakers or to the proprietors or trustees of any railway, tramway, or waterworks, or of any dock, canal, or navigation lawfully entitled to use energy, or to any Government department) in any area being at the passing of this Act the area of supply of any authorised distributors except with the consent of those distributors, but that consent shall not be unreasonably withheld. If any question arises whether that consent is unreasonably withheld, that question shall be determined by the Board of Trade. The consent shall be deemed to be unreasonably withheld if the authorised distributors are not willing and in a position to give the requisite supply upon reasonable terms and within a reasonable time, and in considering what are reasonable terms and what is a reasonable time the Board of Trade shall have regard to all the circumstances of the case, including, amongst other things, the terms upon which and the time within which the company are willing and in a position to give the supply, and the fact (if such be the case) that the undertaking of the authorised distributor is liable to be purchased under the principal Acts.

"4. If at any time after the passing of this Act any local authority, company, or person become authorised distributors in any area within the area of supply under this Act, the company shall be subject to any provisions which may be made by the Act or provisioual order under which the distributors become authorised, as to the taking over of any supply then given by the company for use exclusively within the area of supply of the distributors or otherwise, as to the powers of the company to supply within that area, and such provisions may be made in any such provisional order under the principal Acts."

The new clause, numbered 48A, reads: "The following provisions shall apply and have effect in relation to the supply of energy by the company under the provisions of this Act within the area of any authorised distributor where the consent of such distributor has been withheld:

"1. Where the consent of any such distributor in such area has been withheld, the company, in making application to the Board of Trade to determine whether such consent has been unreasonably withheld, shall deposit with the Board of Trade a statement of prices proposed to be charged by the company in respect of such supply through-

Digitized by Google

out such area not exceeding the price stated in the second schedule to this Act.

"2. In dispensing with any consent under the section of this Act whereof the marginal note is 'conditions affecting supply,' the Board of Trade may, if they think fit, impose upon the company such terms and conditions as the Board may think necessary for the protection of such distributor and for affording a supply of energy under this Act throughout such area, and such terms and conditions may at any time be enforced by such distributor in any court of competent jurisdiction.

"3. The company shall not, after commencing to supply energy within such area, increase the prices in such statement without the consent of the Board of Trade, which consent the Board of Trade are hereby empowered to give.

"4. Where the Board of Trade have dispensed with the consent of such distributor under the section of this Act whereof the marginal note is 'conditions affecting supply,' the company shall, in respect of the supply of energy for providing power to any person within such area, be subject to the same obligations to afford a supply of energy as the authorised distributors therein.

"5. The Board of Trade may, if they think fit, in any case where they have so dispensed with the consent of an authorised distributor, require the company to lay within a period prescribed by the Board suitable and sufficient distributing mains in such streets within the area of such distributor as they think reasonable for affording a supply of energy to persons for power within such area."

Mr. FITZGERALD explained that the total result of all these amendments was that the Board of Trade would have the widest possible power to deal with the circumstances of each particular case. It was quite true that it left the matter in the hands of the Board of Trade, but the greatest difficulty was experienced in trying to frame a clause which would meet the varying conditions of each case which might arise. By leaving it in this way it would enable the Board of Trade to say if the company were going to supply at ¾d., "You must supply in bulk to the authorised distributors at ½d. so that they will be in a position to give a competitive supply."

After further discussion, the CHAIRMAN said that so far as the hardship to the existing companies was concerned, the committee had decided that when they came to deal with the clauses they would insert a clause such as Mr. Fitzgerald had proposed, which in principle, at any rate, would set out what he indicated. The committee had decided that the two Bills could now proceed; but with regard to area, they would give the Administrative County of London Company an area which was understood as the industrial area, and also the area asked for on the south side of the Thames, and also St. Pancras, which was not in the Metropolitan Electric Supply Company's Bill. A portion of Stoke Newington which had been given to the North Metropolitan Company would be taken out of the Administrative Bill. To the Metropolitan Electric Supply Company they would give the area they asked for north of the river.

On Tuesday the clauses of these Bills were further discussed. To the Administrative County of London Bill a new sub-clause was added, which reads: "If the company do not within the prescribed period comply with such requirements, the Board of Trade may order that the powers of the company to distribute energy within such area [except to authorised undertakers or to the proprietors or trustees of any railway, tramway, or waterworks, or of any dock, canal, and navigation entitled to use energy, or to any Government department] shall cease."

On Clause 57 the Chairman pointed out that the standard price which had relation to the sliding scale was fixed in the Bill at 1d., while the standard dividend was 8 per cent. It had been insisted over and over again during the hearing that the promoters could supply at ¾d. or even less, so that it was evident if their anticipations were realised the promoters would have a comfortable dividend of about 11 per cent. to begin with. The promoters agreed to reduce the standard price for the sliding scale to ¾d.

Mr. NIELD, on behalf of other power companies, objected to Clause 65, which allows the Administrative Company to enter into agreements with railway and other companies for the electrical working of their undertakings both inside and outside the area of supply, but the committee accepted the clause.

Opposition was offered to the clause for exempting the generating stations from the London Building Act and the by-laws of the West Ham Corporation. After hearing evidence and argument, the committee passed the clause with the following addition: "this section shall not be deemed to exempt the generating station and works of the company from the operation of the Factory and Workshops Act, 1901."

Mr. FREEMAN, K C, for the Metropolitan Water Board, brought up a clause for the protection of the pipes of the Board against possible damage, and evidence in support of the clause was given by Mr. C. H. Wordingham.

The proposal was ultimately accepted by the committee, a clause being inserted to make the company liable for any damage caused by electrolysis as the result of laying the company's mains.

Other clauses were amended.

The clauses of the Metropolitan Electric Supply Bill were considered and amended, and the two Bills were reported to the House.

## CATALOGUES, ETC, RECEVIED.

METERS.—The International Electric Company, 55, Redcross-street, Barbican, London, E C., have just issued a new illustrated price list of their electricity meters. It includes full particulars of the company's direct-current watt-hour meters (type A. G.), alternate-current watt-hour meters (type A. W.), for single-phase circuits, and prices for ampere-hour meters showing kilowatt-hours at a given voltage.

"ROYAL" DRY CELLS.—From Messrs. Gent and Co., Limited, Faraday Works, Leicester, we have a price list of their "Royal" dry cells. It is claimed that these cells have an extraordinary capacity in ampere-hours when the discharge rate is low, and a correspondingly long life. One special feature in regard to them is the improved carbon terminal, which ensures secure clamping of the line wire without the use of tools.

CABLES.—Messrs. Callender's Cable and Construction Company, Limited, Hamilton House, Victoria-embankment, London, E.C., have issued a catalogue which combines some very excellent features. In the fore part we find the usual tables of dimensions, weights, and resistances of copper conductors in British and metrical units, and British standard sizes of stranded conductors, radial thicknesses for paper dielectric, lead and armour for underground cables, and a table of comparative diameters and weights of high-conductivity copper wire for different wire gauges, etc. Then follow specifications and prices of cables, the different types being illustrated by means of coloured sectional diagrams. Over 40 of these diagrams and specifications are given. Next in order comes some general information of a useful character for reference, and then a series of feeder curves. The latter are intended to give a ready means of arriving at a suitable area of copper conductor for most ordinary cases of supply feeders. In these curves the "line of extreme safe limit of current density" is clearly indicated as a safeguard against running the conductors at a higher current density than is found judicious by experience. Messrs. Callender's private code and a list of useful telegraphic addresses are included at the end.

## PERSONAL.

Mr. David Moonie, superintendent of Aberdeen Corporation tramways, is about to retire on an allowance from the Town Council, and it is proposed that the entire system of electric cars should be put under the control of Mr. J. A. Bell, the city electrical engineer, and that Mr. J. D. Caird, the acting superintendent, be appointed traffic manager.

The salary of the telephone manager at Brighton, Mr. D. J. Barnes, has been increased as from April 1 from £250 to £300 per annum, on the understanding that he is responsible for and is to carry out all works in connection with the extension from time to time of the Corporation telephones undertaking, in addition to the other duties set out in his agreement with the Corporation of March 12, 1903.

Mr. J. R. Williams, A.M.I.E.E., has been appointed to the combined position of chief mechanical engineer and power-station superintendent of the Sheffield Corporation tramways.

The Brighton Town Council have decided to increase the salary of Mr. John Christie, engineer and manager of the Corporation electricity works, from £500 to £750 a year, and thence by annual increments of £50 to £1,000 per annum.

## BOARD OF TRADE REGULATIONS.

We referred last week to the receipt of the revised regulations which the Board of Trade are empowered to issue under the Electric Lighting Acts of 1882 and 1888. The revisions which have been made are in the right direction, and will tend towards the more economical distribution of electrical energy. The regulations have been revised after consultation with those interested in the subject. There are four sets of regulations now to be issued for securing a proper and efficient supply of energy in order to meet the different cases where the authorities are: (1) a local authority in the provinces; (2) a company in the provinces or in the city of London; (3) a company in London, except as to the City; (4) a local authority in London.

The regulations which are given below are those for a local authority in the provinces. They are practically the same as those for the other three cases, except as regards details which are not of a technical nature. For instance, under the regulation for provision of constant supply a company in the provinces has to obtain the consent of the local authority before an intermittent supply can be given. In London the consent of the London County Council, as well as that of the local authority, has to be obtained by a supply company. In both cases, however, the Board of Trade consent is dispensed with. In the case of a local authority in London, the London County Council has to be consulted. Again, in the third clause of Section B and in the fourth clause of the same section, dealing respectively with the declared pressure at consumers' terminals and the declared frequency and system of supply, much the same alterations are made. In the event, however, of the consent of the local authority or of the London County Council to the proposed changes being withheld, the matter can be referred to the Board of Trade. It is interesting to compare the alterations which have been made in these new regulations as compared with those which were issued previously. Amongst these is the omission of a limit in amount of energy which may be transmitted through a given high-pressure cable. Extra high-pressure current can now be delivered to a factory, or mine, subject to the regulations which have been issued by the Home Office. The variation allowed in frequency is now fixed at 2½ per cent. up or down, and the variation in voltage remains at 4 per cent. up or down. Other points in connection with the fusing of networks have been made which will, we think, give general satisfaction. The full draft of the regulations reads as follows:

*Definitions.*

In the following regulations

The expression "the order" means the ————

The expression "the undertakers" means the undertakers for the purposes of the order.

The expression "consumer's wires" means any electric lines on a consumer's premises which are connected with the service lines of the undertakers at the consumer's terminals.

The expression "sub-station" means any premises in which energy is transformed or converted for the purpose of supply to consumers, and which are large enough to admit the entrance of a person after the transforming or converting apparatus is in position, provided that for the purpose of these regulations any place within any such premises which is used solely for some purpose other than such transformation or conversion shall not be deemed to form part of a sub-station.

The expression "overhead line" means any electric line which is placed above ground and in the open air.

The expression "pressure" means the difference of electrical potential between any two conductors through which a supply of energy is given, or between any part of either conductor and the earth; and, subject to the variations allowed by No. B 3 of these regulations: (*a*) where the conditions of the supply are such that the pressure at any pair of consumer's terminals does not exceed 250 volts, the supply shall be deemed a low-pressure supply; (*b*) where the conditions of the supply are such that the pressure exceeds 250 volts, but does not exceed 650 volts, the supply shall be deemed a medium-pressure supply; (*c*) where the conditions of the supply are such that the pressure exceeds 650 volts, but does not exceed 3,000 volts, the supply shall be deemed a high-pressure supply; and (*d*) where the conditions of the supply are such that the pressure exceeds 3,000 volts, the supply shall be deemed an extra high-pressure supply.

The expression "factory" has the same meaning as in the Factory and Workshop Act, 1901.

The expression "mine" means a mine to which the Coal Mines Regulation Act, 1887, or the Metalliferous Mines Regulation Act, 1872, applies.

Where these regulations require any metallic body to be "efficiently connected with earth," it shall be connected with the general mass of earth in such manner as will ensure at all times an immediate and safe discharge of electrical energy.

Other expressions to which meanings are assigned in the order or in the Electric Lighting Acts, 1882 and 1888, have the same respective meanings in these regulations.

A.—Regulations for Securing the Safety of the Public.

*General.*

1. *Pressure of Supply to Consumers.*—The pressure of a supply delivered to any consumer shall not exceed the limit of low pressure except for special purposes, for which a medium-pressure supply may be given on the consumer undertaking to comply with the following conditions:

(*a*) Where the supply is for power purposes—(1) The frame of every electric motor shall be efficiently connected with earth. (2) The consumer's wires forming the connections to motors, or otherwise in connection with the supply, shall be, as far as practicable, completely enclosed in strong metal casing efficiently connected with earth, or they shall be fixed in such a manner that there shall be no danger of any shock. (3) The supply to every motor shall be controlled by means of an efficient cut-off switch, placed in such a position as to be easily handled by the person in charge of the motor, and connected so that by its means all pressure can be cut off from the motor itself, and from any regulating switch, resistance, or other device in connection therewith. (4) Switches, efficient fuses, or other automatic circuit breakers shall be provided so as to protect the circuits from excess of current, and all switches and cut-outs shall be so enclosed and protected that there shall be no danger of any shock being obtained in the ordinary handling thereof, or of any fire being caused by their normal or abnormal action. (5) A notice shall be fixed in a conspicuous position at every motor and switchboard in connection with the supply forbidding unauthorised persons to touch the motors or apparatus.

(*b*) Where the supply is for arc lamps in series—(1) The consumer's wires forming the connections to the arc lamps, or otherwise in connection with the supply, shall be, as far as practicable, completely enclosed in strong metal casing efficiently connected with earth, or they shall be fixed in such a manner that there shall be no danger of any shock. (2) The supply to every arc lamp shall be controlled by means of an efficient cut-off switch, placed in such a position as to be easily handled by the person in charge of the arc lighting, and connected so that by its means all pressure can be cut off from the arc lamp itself, and from any regulating switch, resistance, or other device in connection therewith. Provided that where the arc lamps are connected in series across the outer conductors of a three-wire system, it shall be sufficient if one such switch be provided for each series of arc lamps. (3) Switches, efficient fuses, or other automatic cut-outs shall be provided so as to protect the circuits from excess of current, and all switches and cut-outs shall be so enclosed and protected that there shall be no danger of any shock being obtained in the ordinary handling thereof, or of any fire being caused by their normal or abnormal action.

(*c*) Where the supply is for incandescent lamps in series—(1) The consumer's wires forming the connections to the incandescent lamps, or otherwise in connection with the supply, shall be completely enclosed in strong metal casing, and this casing, together with the switches and lampholders, if metallic, shall be efficiently connected with earth. (2) Switches, efficient fuses, or other automatic cut-outs shall be provided so as to protect the circuits from excess of current, and all switches and cut-outs shall be so enclosed and protected that there shall be no danger of any shock being obtained in the ordinary handling thereof, or of any fire being caused by their normal or abnormal action.

When the supply is for any special purpose other than those above mentioned, or where the pressure of the supply exceeds the limits of medium pressure, it shall be subject to such other regulations as the Board of Trade may from time to time prescribe.

2. *Introduction of Three-Wire System into Consumer's Premises.*—When the pressure between the outer conductors of a three-wire system exceeds 250 volts and the three wires of the system or two pairs of wires are brought into a consumer's premises, the supply shall be given to two pairs of terminals arranged in such a manner that there shall be no danger of any shock, and the wiring from those terminals shall be kept distinct.

3. *Extra High-Pressure Supply to Consumer's Premises.*—An extra high-pressure supply shall not be given to any consumer's premises other than a factory, a mine, or electric traction

Digitized by Google

works; and no such supply shall be given except with the consent of the Board of Trade and subject to such regulations as the Board may prescribe.

4. *Minimum Size of Conductors.*—The sectional area of the conductor in any electric line laid or erected in any street after the date of these regulations shall not be less than that of a strand of seven wires, each of which is of No. 20 standard wire gauge, and the sectional area of every wire in a strand forming any such conductor shall not be less than that gauge. This regulation shall not apply in the case of an electric line placed in a lamp-post.

5. *Insulation Test of Low-Pressure and Medium-Pressure Mains.*—Every low-pressure and medium-pressure main shall be tested for insulation after having been placed in position and before it is used for the purposes of supply, the testing pressure being the maximum pressure to which it is intended to be subjected in use, and in any case at least 200 volts, and the undertakers shall duly record the results of the tests of each main, or section of a main.

6. *Maintenance of Insulation.*—The insulation of every complete circuit used for the supply of energy, including all machinery, apparatus, and devices forming part of, or in connection with, that circuit, shall be so maintained that the leakage current shall not under any conditions exceed one-thousandth part of the maximum supply current; and suitable means shall be provided for the indication and localisation of leakage. Every leakage shall be remedied without delay. Every such circuit shall be tested for insulation at least once in every week, and the undertakers shall duly record the results of the testings. Provided that where the Board of Trade have approved of any part of any electric circuit being connected with earth, the provisions of this regulation shall not apply to that circuit so long as the connection with earth exists.

7. *Testing of Insulation of all Parts of High-Pressure Circuit.* A high-pressure circuit shall not be brought into use unless the insulation of every part thereof has withstood the continuous application, during half an hour, in the case of every electric line of a pressure twice the maximum pressure to which it is intended to be subjected in use, and, in the case of every machine, device, or apparatus, of a pressure 50 per cent. greater than the said maximum pressure. The undertakers shall duly record the results of each test.

8. *Circuit Breaker for High-Pressure Mains, etc.*—Every high-pressure main, conductor, or other apparatus shall be protected by a suitable fuse or automatic circuit breaker. Provided that it shall not be incumbent upon the undertakers to provide such a fuse or circuit breaker for the outer conductor of a concentric main which is, with the approval of the Board of Trade, efficiently connected with earth.

9. *Transformers.*—In every case where a high-pressure supply is transformed for the purpose of supply to one or more consumers, some suitable automatic and quick-acting means shall be provided to protect the consumer's wires from any accidental contact with or leakage from the high-pressure system, either within or without the transforming apparatus.

10. *Connection of Transformers with Earth.*—The metallic portion of every transformer, with the exception of the conductors thereof, shall be efficiently connected with earth.

11. *Protection from Lightning.*—Where any portion of any electric line or any support for an electric line is exposed in such a position as to be liable to cause injury from lightning, it shall be efficiently protected against such liability.

12. *Report of Accidents to Board of Trade.*—Where any accident by explosion or fire, or any other accident of such kind as to have caused or to be likely to have caused loss of life or personal injury, has occurred at any part of any electric line or work, the undertakers shall give immediate notice thereof to the Board of Trade.

*Overhead Lines.*

13. *Overhead Lines.*—Overhead lines shall not after the date of these regulations be erected or maintained except in accordance with plans approved by the Board of Trade and subject to such regulations as the Board may prescribe. Provided that this regulation shall not apply to any electric lines which have been erected at the date of these regulations so long as those lines are maintained in accordance with any regulations of the Board of Trade which are in force and applicable thereto at that date and with any requirements of the Board made thereunder.

*Electric Lines other than Overhead Lines.*

14. *Construction of Receptacles for Electric Lines.*—All conduits, pipes, casings, and street boxes used as receptacles for electric lines shall be constructed of durable material, and where laid under carriageways shall be of ample strength to prevent damage from heavy traffic, and reasonable means shall be taken by the undertakers to prevent accumulation of gas in such receptacles.

15. *Crossing Pipes, etc.*—Where any electric line crosses, or is in proximity to, any metallic substance, special precautions shall be taken by the undertakers against the possibility of any electrical charging of the metallic substance from the line or from any metal conduit, pipe, or casing enclosing the line.

16. *Electric Continuity of Metal Conduits, Pipes, and Casings of High-Pressure Line.*—All metal conduits, pipes, or casings containing any high-pressure electric line shall be efficiently connected with earth, and shall be so jointed and connected across all street boxes and other openings as to make good electrical connection throughout their whole length.

17. *Precautions to be taken when Bare Conductors are used.*—Where the conductors of electric lines placed in any conduit are not continuously covered with insulating material they shall be secured in position, and no unfixed uninsulated material of a conducting nature shall be contained in the conduit. No such conductor shall be at a pressure exceeding 300 volts from earth. Adequate precautions shall also be taken to ensure that no accumulation of water shall take place in any part of the conduit, and to prevent any dangerous access of moisture to the conductors or the insulators. The insulators of any such electric line shall be so disposed that they can be readily inspected, but this requirement shall not apply to any such insulators which before the date of these regulations were not required by any regulation then in force to be so capable of ready inspection.

18. *High-Pressure Lines laid above Ground or in Subways.*—Every portion of any high-pressure electric line placed above the surface of the ground, or in any subway not in the sole occupation of the undertakers, shall be completely enclosed either in a tube of highly insulating material embedded in brickwork, masonry, or cement concrete, or in strong metal casing efficiently connected with earth.

19. *Protection for the Surface of the Ground and Electric Lines.*—Where any high-pressure electric line is laid beneath the surface of the ground, efficient means shall be taken to render it impossible that the surface of the ground or any neighbouring electric line or conductor shall become charged by leakage from the high-pressure electric line.

20. *Completion and Control of High-Pressure Lines.*—A high-pressure electric line shall not be used for the supply of energy before it has been completely laid, properly jointed, examined, and tested, or until it is in the sole charge of the undertakers, and every such line shall during its use be in the sole charge of the undertakers.

*Sub-Stations and Street Boxes.*

21. *Sub-Stations.*—Sub-stations shall be established in suitable places and shall be in the sole occupation and charge of the undertakers. Sub-stations shall be erected above ground wherever possible, but where necessarily underground they shall be constructed in accordance with plans approved by the Board of Trade.

22. *Street Boxes.*—In addition to the provisions contained in Regulation 14 as to the construction of receptacles for electric lines, the following conditions shall be observed with respect to street boxes: (*a*) The covers of all street boxes shall be so secured that they cannot be opened except by means of a special appliance. (*b*) The covers of all street boxes containing high-pressure apparatus other than cables shall be connected to strips of metal laid immediately underneath the street, and efficient means shall be taken to render it impossible that the covers or other exposed parts of these boxes, or any adjacent material forming the surface of the street, shall become electrically charged, whether by reason of leakage, defect, or otherwise. (*c*) Where street boxes are used as transformer chambers, reasonable means shall be taken to prevent as far as possible any influx of water, either from the adjacent soil or by means of pipes; and in the case of any such street box exceeding one cubic yard in capacity, ample provision shall be made, by ventilation or otherwise, for the immediate escape of any gas which may by accident have obtained access to the box, and for the prevention of danger from sparking. (*d*) All street boxes shall be regularly inspected for the presence of gas, and if any influx or accumulation is discovered, the undertakers shall give immediate notice to the authority or company whose gas-mains are laid in the neighbourhood of the street box. (*e*) Where mains at different pressures pass through the same street box they shall be readily distinguishable from one another.

23. *Maximum Power in Case of Underground Sub-Station, etc.*—The maximum power supplied to any underground sub-station or street box shall not, without the consent of the Board of Trade, exceed 30 kw. in the case of a sub-station or street box containing a single transformer, or 75 kw. in the case of a sub-station or street box containing two or more transformers.

*Consumer's Premises.*

24. *Responsibility of Undertakers for their Lines, etc., on Consumer's Premises.*—The undertakers shall be responsible for all electric lines, fittings, and apparatus belonging to them, or under their control, which may be upon a consumer's premises being maintained in a safe condition and in all respects fit for supplying energy.

25. *Fire Risks.*—In delivering the energy to a consumer's terminals the undertakers shall exercise all due precautions so as to avoid risk of causing fire on the premises.

Digitized by Google

26. *Main Fuses or Circuit Breakers.*—A suitable safety fuse or other automatic circuit breaker shall be inserted in each service line within a consumer's premises as close as possible to the point of entry, and contained within a suitable locked or sealed receptacle of fireproof construction, except in cases where the service line is protected by fuses in a street box; but no fuse or automatic circuit breaker shall be inserted in the intermediate conductor of a three-wire system where the pressure between the adjacent conductors exceeds 125 volts.

27. *Treatment of Service Lines and Apparatus on Consumer's Premises.*—All service lines and apparatus placed on a consumer's premises shall be highly insulated and thoroughly protected against injury to the insulation or access of moisture, and any metal forming part of the electric circuit shall not unless efficiently connected with earth be exposed so that it can be touched. All electric lines shall be so fixed and protected as to prevent the possibility of electrical discharge to any adjacent metallic substance.

28. *Transformers and High-Pressure Apparatus to be Enclosed in Metal, etc.*—Where the general supply of energy is a high-pressure supply, and transforming apparatus is installed on a consumer's premises, the whole of the high-pressure service lines, conductors, and apparatus, including the transforming apparatus itself, so far as they are on the consumer's premises, shall be completely enclosed in solid walls, or in strong metal casing efficiently connected with earth and securely fastened throughout.

29. *Connection to Consumer's Premises not to be made where Leakage would result.*—The undertakers shall not connect a consumer's wires with their mains unless they are reasonably satisfied that the connection would not cause a leakage from those wires or fittings exceeding one ten-thousandth part of the maximum supply current to the premises; and where the undertakers decline to make such connection they shall serve upon the consumer a notice stating their reasons for so declining.

30. *Discontinuance of Supply on Discovery of Leakage on Consumer's Premises.*—If the undertakers are reasonably satisfied, after making all proper examination by testing or otherwise, that a leakage exists at some part of a consumer's wires or fittings of such extent as to be a source of danger, any officer of the undertakers, duly authorised by them in writing, or, if the undertakers so require, an electric inspector, may, for the purpose of discovering whether the leakage exists at any part of a circuit within or upon any consumer's premises, by notice require the consumer at some reasonable time after the service of the notice to permit him to inspect and test the wires and fittings belonging to the consumer and forming part of the circuit. In any case where the undertakers require the services of an electric inspector under this regulation they shall pay him the prescribed fee. If on any such testing the officer or the electric inspector discovers a leakage from the consumer's wires exceeding one ten-thousandth part of the maximum supply current to the premises, or if the consumer does not give all due facilities for inspection and testing, the undertaker shall forthwith discontinue the supply of energy to the premises in question, giving immediate notice of the discontinuance to the consumer, and shall not recommence the supply until they are reasonably satisfied that the leakage has been removed. This regulation shall not affect any power contained in the order or otherwise enabling the undertakers to discontinue the supply.

31. *Appeal to Electric Inspector.*—If any consumer is dissatisfied with the action of the undertakers in refusing to give, or in discontinuing, or in not recommencing the supply of energy to his premises, the wires and fittings of that consumer shall, on his application, and on payment of the prescribed fee, be tested for the existence of leakage by an electric inspector. This regulation shall be endorsed on every notice given under the provisions of either of the two last preceding regulations.

*Arc Lighting.*

32. *Height from Ground.*—Arc lamps used in any street for public lighting shall be so fixed as not to be in any part at a less height than 10ft. from the ground.

33. *Arc Lamps to be Guarded.*—All arc lamps shall be so guarded as to prevent pieces of ignited carbon or broken glass falling from them, and shall not be used in situations where there is any danger of the presence of explosive dust or gas.

*Connection of Circuits with Earth.*

34. *Connection with Earth of a Three-Wire System.*—Where the pressure of a supply between the adjacent conductors of a three-wire system of mains exceeds 125 volts, the intermediate conductor shall be connected with earth, subject to the concurrence of the Postmaster-General, and in accordance with the following conditions: (*a*) the connection with earth of the intermediate conductor shall be made at one point only on each distinct circuit—namely, at the generating station, sub-station, or transformer—and the insulation of the circuit shall be efficiently maintained at all other parts; (*b*) the current from the intermediate conductor to earth shall be continuously recorded, and if it at any time exceed one-thousandth part of the maximum supply current, steps shall be immediately taken to improve the insulation of the system.

*Penalties.*

35. *Penalties for Default.*—If the undertakers make default in complying with any of the preceding regulations, they shall, on conviction, be liable to a penalty not exceeding £10 for every such default, and to a daily penalty not exceeding £10. The recovery of a penalty under these regulations shall not affect the liability of the undertakers to make compensation in respect of any damage or injury which may be caused by reason of the default.

B.—Regulations for Ensuring a Proper and Sufficient Supply of Electrical Energy.

1. *Undertakers to Provide Constant Supply.*—From the time when the undertakers commence to supply energy through any distributing main, they shall maintain a supply sufficient for the use of all the consumers for the time being entitled to be supplied from that main; and that supply shall, except so far as the Board of Trade may otherwise from time to time permit, be constantly maintained, and in the case of continuous currents, without change of polarity. Provided that, for the purposes of testing, or for any other purposes connected with the efficient working of the undertaking, the authority by whom the electric inspector is appointed may give permission to the undertakers to discontinue the supply at such intervals of time and for such periods as that authority may think expedient. When the supply is so discontinued, or the polarity is changed, notice to all persons likely to be affected shall be given of such discontinuance or change, and of the probable duration thereof.

2. *Measures for Restricting Area Liable to Stoppage.*—The system of distributing mains shall be separated into sections corresponding approximately to the different feeders, and these sections shall be interconnected only through suitable circuit breakers or fuses arranged so as to be readily inspected.

3. *Fixing of Declared Pressure at Consumer's Terminals.*—Before commencing to give a supply of energy to any consumer, the undertakers shall declare to that consumer the constant pressure at which they propose to supply energy at his terminals. The pressure so declared shall be constantly maintained, subject to a variation not exceeding 4 per cent. under any conditions of supply which the consumer is entitled to receive, or such other variation as the Board of Trade may from time to time allow, and shall not be altered or departed from to an extent greater than that variation except by consent of the Board of Trade, and upon such terms and conditions as the Board of Trade may impose, and after public notice has been given during a period of one month, in such manner as the Board of Trade may require, of the intention of the undertakers to apply for consent to alter the same. Provided that any regulation in force at the date of these regulations whereby the consent of any consumer (or in default thereof the consent of the Board of Trade) was then required to a change in the declared constant pressure to that consumer's premises shall, notwithstanding anything in these regulations, continue of full force and effect in the case of any consumer whose consent was then so required, and shall apply in that case as if it had been expressly set out in these regulations.

4. *Fixing of System and Declared Frequency.*—Before commencing to give a supply of energy to any consumer, the undertakers shall declare to that consumer the system which they propose to adopt, whether alternating or continuous current, and in the case of alternating current the frequency—that is to say, the number of complete periods per second at which they propose to supply. The system and frequency so declared shall be maintained subject, as respects frequency, to a variation not exceeding 2½ per cent. from the declared frequency, and shall not be altered or departed from except by consent of the Board of Trade, and upon such terms and conditions as the Board of Trade may impose, and after public notice has been given during a period of one month, in such manner as the Board of Trade may require, of the intention of the undertakers to apply for consent to alter the same.

5. *Penalty for Default.*—If the undertakers make default in complying with any of these regulations as to supply, they shall, subject to the provisions of the order, be liable on conviction to a penalty not exceeding £5 for every such default, and to a daily penalty not exceeding £5.

These regulations are made subject to the power of the Board of Trade to make such further or other regulations as they may think expedient; and nothing in these regulations shall be construed to authorise the undertakers to lay any electric line or work their undertaking otherwise than in accordance with the order and the principal Act, or to supply energy otherwise than by a system for the time being approved of by the Board of Trade under the order.

These regulations are, so far as they relate to factories and mines, in addition to and not in substitution for any regulations made by a Secretary of State under any Act relating to factories or mines.

## INSTITUTION OF ELECTRICAL ENGINEERS.

The following is an abstract of the discussion upon Mr. H. L. Webb's paper entitled "Telephone Traffic," which was illustrated by the mutoscope:

Mr. J. GAVEY referred to the economy in the time of the exchange assistant effected by automatic signalling as compared with the magneto principle. He calculated that the operator could render double the amount of service under the former system. There was also a saving on floor space. In addition, there was an economy in a large exchange system like that of London, where 20 to 25 per cent. of the lines were devoted to junction purposes, as the junction connection in a magneto system occupied 79·55 seconds against 38·97 seconds for the relay system.

Mr. W. W. COOK pointed out that it might be inferred from the paper that the introduction of supervisory signals was the result of the introduction of signal lamps, but this was incorrect, as supervisory signals could have been attained without signal lamps. At the same time he readily admitted the utility of lamp signals, which enabled the operator to have a continuous knowledge of what was going on, but this knowledge was not the whole secret of the effectiveness of the modern supervisory signal. The operator needed to know what was happening on each side of the cord circuit, and this was attained by the common battery system. He defended the reliability of the ring-off indicator, but admitted that it had three weaknesses—it had to be worked by the subscriber, who was called upon to perform an action that had no necessary connection with what he was attempting to do; it did not give continuous supervision; and it did not provide the operator with independent knowledge of what was going on. A system of supervisory signals was good or bad according to the degree in which it obviated listening in. He quoted some figures from New York showing that with the magneto system the operator had to come into circuit on an average 5½ times, the time occupied for a local call being 14 seconds, and for a junction call 16 seconds. The introduction of the common battery system disposed of this and maintained the integrity of the connection. The only possible uncertainty with the present system of supervisory signals was whether the calling signal being alight meant that the subscriber had not replied, and whether he had replied and gone away, though in practice the operator had no difficulty in distinguishing. In order to make a test another lamp might be added, which could only come into circuit after the subscriber had answered.

Mr. J. E. KINGSBURY calculated that there must be some 5,000,000 telephonic messages sent in the United Kingdom daily. He emphasised the economy that might be effected in regard to the switchboard by stating that everything in the switchboard, except the line, depended upon the traffic, the only fixed item being the material connected to one line, which had to be there whether the traffic was large or small. Regarding the evolution of the switchboard, he agreed with the author that the proximity of the answering jack and lamp signal was a great advantage, but it was not a modern discovery.

Mr. S. J. GODDARD would have liked more information about traffic. There were four important points to be considered in the study of this—the number of calls made by the individual subscriber, which it was essential to know in order to distribute the work equally between the operators; the variation of traffic during the busy hours of the day; the state of the junction traffic; and the methods of dealing with the calls by the operators and the subscribers. This called for constant observation of the operator's method.

Mr. D. H. KENNEDY related the results of tests he had made with a stop-watch in order to complete the operation denoted as A in the author's diagrams—observing the lamp, plugging in, and replying to the subscriber. He had found it possible to perform this in one second. The Post Office system used a pilot lamp for each 60 subscribers. In the course of his experiments he found it necessary to put the pilot lamps out of service, which retarded the operation by nine seconds. The speaker described other tests, showing that a junction call involved four individuals in 16 mental operations, and the quickest time in which these could be performed was 7½ seconds. The panels were of triple design, and he noticed that those on the right hand could be dealt with more quickly than those on the left or in the centre. The author had divided the history of telephonic development into two periods, which he (the speaker) thought involved more than was shown in the paper. During the first period of 16 years English engineers took a fair share in telephonic development, but during the latter period of eight years most of the improvements had been due to America, although English engineers had held their own in cable design. For more than 20 years the Post Office had possessed a system which had many of the attributes of the common battery system. He considered that the progress in America was due to competition.

Mr. F. GILL said the author's figures regarding New York showed a high standard of efficiency. He recognised that American engineers were a very capable class, but he would claim one point for this country—that positive disconnecting signals were used here in 1892, some time before the lamp signal. Turning to the financial side, which had been omitted from the paper, he strongly advocated a flat rate, as in New York. The trouble with engaged lines had been materially reduced in that city by relay apparatus and the double-supervision system. The London lines were more heavily loaded than those of New York by some 25 per cent., which meant that the plant had to carry an extra load.

Briefly replying, Mr. WEBB expressed gratification that no one had seriously quarrelled with his paper. He had no desire to parade the efficiency of New York, but simply gave it as a suitable illustration. The paper, he was glad to say, had achieved its main object, which was to provide an opportunity for discussing telephonic development.

A vote of thanks was unanimously accorded the author.

# LEGAL INTELLIGENCE.

## WATER SUPPLY.

In the Chancery Division last week Mr. Justice Farwell had before him the case of the Birmingham Corporation *v.* the Birmingham Canal Navigation Company, which concerned the right of the Corporation to take water from the canal for the purposes of their generating station at Summer-lane for the purposes of electric lighting. The plaintiffs asked for a declaration that they are entitled to take water from the Birmingham and Fazeley Canal for condensing and other purposes in connection with their steam-engines, or for such other relief as the nature of the case required. The defendants contended that a generating station did not come within the statute controlling such matters, and therefore the plaintiffs had no right to take the water from the canal.

After hearing the arguments of counsel on both sides, his Lordship said he wished to consider his decision, and accordingly reserved judgment.

## OPENING STREETS.

The opinion of Mr. Justice Warrington was asked last week as to the meaning of certain words in the Acts of Parliament empowering the London and United Tramways, Limited, to construct electric tramways in Surbiton, Kingston, and Wimbledon.

The company propose to lay down a line of cables to pass through the boroughs of Wandsworth, Fulham, and Chelsea to connect the tramways at Wimbledon with the generating station in Lots-road, Chelsea (owned by another body), some five miles distant. The words in their Acts which they say enable them to do this are: "The company may execute all such works . . . as may be necessary or convenient for the working of the tramways by mechanical power . . . or for providing access to or forming connections with any generating station," etc.

Mr. CRIPPS, K.C., moved on behalf of the local authority that the company might be restrained from breaking up roads within the borough of Wandsworth, contending that they had no power whatever under their Acts to do this.

Mr. BALFOUR BROWNE, K.C., contended that there was no obligation on the part of the company to provide their own generating station, and in fact it was quite a common thing for local authorities to insist upon supplying the power themselves. His learned friend characterised as absurd the company's claim to connect with "any generating station," saying that if they were right they might go as far as John o' Groats for their electrical energy. There was, however, a very practical answer to that argument. It would not pay to go any great distance.

Mr. JUSTICE WARRINGTON held that there was nothing in the Act to confine the words "for providing access to or forming connections with any generating station" to a generating station belonging to the company, or that in making the connections the company were confined to the streets in which the trams were to run. The learned judge added, however, that, assuming his construction of the section to be right, he had heard no argument or evidence on the point as to whether the proposed cable was necessary or convenient.

The motion was accordingly dismissed, the costs to be the costs of the action.

## STREET ELECTRIC BOXES.

Before Mr. Justice Grantham and a special jury the action of Hayward *v.* Mayor and Corporation of Ealing came on for hearing. Plaintiff, an Ealing fruiterer, claimed damages for injuries alleged to have been sustained through a street electric box. He asserted that he was standing outside his shop in May last year with one foot upon the box when he received an electric shock which caused his leg to give way. It was found that the knee-cap had been fractured, and medical evidence was called for plaintiff to prove that the sudden contraction of the muscles caused by an electric shock would produce the injury to the knee. Defendants denied that the box was defective, and alleged that the injury was caused by plaintiff slipping, the box cover being wet at the time.

GEORGE MUNDY, electrician, called on behalf of the plaintiff, described experiments which he had made in connection with the box. He said that with the full voltage of 102 applied there was a tense sensation, and his feet appeared glued to the spot. When the current was switched off his legs collapsed, but he did not fall in the manner described by the plaintiff.

HIS LORDSHIP, in summing up, remarked that if the plaintiff did receive a shock, it must have been caused by the cover. There was, however, a great deal of expert evidence to show that he was mistaken. So far as he knew, there was no instance of a human being having such a shock as was now alleged.

The jury disagreed, and were discharged.

HIS LORDSHIP said the case was full of difficulties, and if he had been on the jury he should have expected a disagreement.

## ALLEGED SMOKE NUISANCE.

At Jarrow last week the County of Durham Electric Power Distribution Company was summoned at the instance of the Corporation, under the Public Health Act, through black smoke being emitted from the chimney of their power station.

At the outset of the proceedings, Mr. BURTON, who represented the company, suggested that the case should be adjourned. He denied that there was any nuisance created, but such smoke as was emitted from the chimney would soon be stopped altogether. The company

Digitized by Google

had entered into an arrangement by which electricity required for the town would be made at the other side of the river, and the power station would in future be used only as a transmission station. When that was carried out there would be no more smoke created there.

Evidence having been given as to the emission of the smoke, Mr. JOSEPH STANHOPE WATSON, technical manager to the defendants, said the company was laying cables from Wallsend to Jarrow, and when the work was completed the steam plant at the station would be shut down. It was expected that the work would be finished by the end of June.

The magistrates considered in private, and on returning to court the CHAIRMAN said the justices considered the offence proved, and they made an order for the nuisance to be abated within two months and to pay the costs. If the order was not complied with in the time stated a substantial daily penalty would be fixed.

# COMPANIES' MEETINGS AND REPORTS.

## WESTERN TELEGRAPH.

The ordinary general meeting of this Company was held last week at River Plate House, Sir John Wolfe Barry presiding.

The CHAIRMAN said that the commerce of South America had steadily increased, and the vast resources of the country were being satisfactorily developed. The Company had participated in this progress, the message receipts having amounted to £227,324 as compared with £202,062 in the corresponding period of last year. The revenue amounted to £218,264 and the working expenses to £105,547. After providing for debenture stock and debenture interest and sinking fund, and £4,821 for income tax, there remained a balance of £123,831, which, with £4,439 brought forward, made a total of £128,270. First and second interim dividends amounting to £62,379 had been paid, and after transferring £60,000 to the general reserve fund and £2,600 to the maintenance ships' reserve fund there remained £3,891 to carry forward.

The report was unanimously adopted.

## CAPE ELECTRIC TRAMWAYS.

In accordance with a requisition, an extraordinary general meeting of the Cape Electric Tramways, Limited, was held last week at Salisbury House for the purpose of submitting a resolution instructing the directors not to purchase the tramways of the Cape Town Consolidated Tramways and Land Company, Limited, either under the option to purchase or otherwise, and not to renew the lease thereof; also to elect a director or directors to fill any vacancy on the Board.

Mr. L. BREITMEYER, who presided, stated that the Board had convened the meeting under compulsion, but it was quite superfluous, because the requisitionists asked for something which they had already obtained. As far back at the last annual meeting the directors stated that they would not deal with this Camps Bay property, nor even with its lease, without reference to the shareholders, and these assurances were repeated in more definite and precise form at the special meeting held on April 19 last. With these pledges by the directors the majority of the shareholders were quite satisfied, accepting them in the same *bona fide* manner as they were made. With the voting power held by the directors it would be an easy matter for them to vote against the resolution of the requisitionists or to substitute any amendment; but the demand of the requisitionists was identical with the policy of the Board, as often expressed previously, and for that reason they accepted the resolution, which he begged formally to move.

Mr. PARRISH, in seconding the resolution, said that in the notice calling the meeting the secretary stated that his directors had on three separate occasions definitely stated that they did not intend to purchase the tramways of the Cape Town Consolidated Tramways and Land Company, Limited, or to renew the lease thereof. If this were the case, he had never heard of it, and, in fact, he did not think it was so. The chairman at the last general meeting, held in November last, made some general statements on the subject which in no way could bind the Board. The only way the Board could declare itself clear on the matter was to pass a resolution and enter it on the minutes, which he had never heard had been done. But even if this were done, it could be altered at any time a quorum was present to do so. The speaker proceeded to give a general review of the position of affairs in recent years.

After some discussion, the resolution was carried unanimously, and Mr. Rommel was elected to the vacancy in the directorate.

## ELECTRIC LIGHTING AND TRACTION COMPANY OF AUSTRALIA.

The fifth annual meeting of this Company was held at Winchester House on Monday, Mr. J. B. Braithwaite presiding.

In moving the adoption of the report, the CHAIRMAN said that when they came to analyse the profits of the separate stations it was very significant and encouraging to find that Melbourne headed the list, as some of their difficulties in the past had been due to the relatively slow growth of their business there. The total lamp connections stood at 130,232, as compared with 89,644 lights at the close of the preceding financial year. With regard to the South Australian undertakings, he stated that, in view of possible developments, it had been thought advisable to separate them from the rest of the business. They had, therefore, formed the Adelaide Electric Supply Company, Limited, which had made an issue of £50,000 in 6 per cent. cumulative preference shares. The result of the change was that this Company for their expenditure of £115,000 on the Adelaide and Port Adelaide undertakings, had received £127,500 in the ordinary shares of the new company and also £35,000 in cash. This sum would be employed in the development of their Melbourne and Geelong businesses. After providing for debenture interest, banker's interest, standing charges, etc., there was a debit balance on the year's working of £4,666, which raised the total debit balance to £12,088. The returns for the first six months of the current year, which were the summer months, were almost exactly double those for the corresponding period of the previous year. However, the winter months were those which controlled the situation, and he hardly thought that they could count on the winter revenue showing so great an improvement.

The accounts were adopted.

## BRISBANE ELECTRIC TRAMWAYS INVESTMENT.

The fourth annual general meeting of the Brisbane Electric Tramways Investment Company, Limited, was held at Winchester House, under the presidency of Sir Malcolm D. McEacharn.

The CHAIRMAN stated that the Brisbane Tramways Company, in which this Company is interested, had placed to the credit of renewals fund £3,000, paid in dividends £44,000, and carried forward £2,908. Taking the dividends received from that source, adding thereto the amount brought forward from last year, etc., and deducting the London and Brisbane charges, there was a net balance available of £44,239. The debenture stock interest had absorbed £18,188. The directors proposed to set aside to reserve fund £5,000, bringing the same up to £14,216, to start an accidents insurance fund with the sum of £500, and after payment of the full 5 per cent. on the preference shares there would remain the sum of £2,719 to carry forward to next account. Notwithstanding the opening of the Toowong extension in July last year, and an increased car mileage run in that year of some 85,000 miles, the traffic receipts showed an increase of only £543 as compared with the year 1903. The receipts on the Toowong line from the date of opening—July 23, 1904—to Dec. 31, 1904, amounted to £3,627, thus showing a falling off on the other lines of £3,084 in 1904 as compared with 1903. On the other hand, it was satisfactory to note that, notwithstanding the increased mileage, the expenditure had been kept down in every possible direction, and was less than in 1903, the net result for both years being practically the same. Queensland had been undergoing a period of severe industrial depression, but there were indications of returning prosperity.

The report was adopted unanimously.

## ORIENTAL TELEPHONE AND ELECTRIC.

The Oriental Telephone and Electric Company, Limited, have convened a meeting for the 31st inst., when a resolution will be proposed empowering the directors to create debenture stock to the extent of £200,000, and to issue it from time to time as they may deem expedient.

The Board states that the raising of further capital has now become necessary to provide for the reconstruction and extension of the Company's installations to comply with the requirements of the Governments of India, the Straits Settlements, and Hong-Kong, and for the development of the growing business of the Company and its associated companies. The directors consider that such further capital will be used with much advantage to the Company's business. They have carefully considered and taken advice with regard to the cheapest and most desirable mode of raising it, and are of opinion that the creation of debenture stock is the course most favourable to the interests of the shareholders.

## WEST AFRICAN TELEGRAPH.

The report for 1904, to be presented to the meeting on May 31, states that revenue for the period under review amounted to £60,914, from which is deducted £14,994 for ordinary expenses and £9,840 for expenditure relating to maintenance of cables, leaving a balance of £36,080, to which is added £2,663 brought from the preceding year, making a total available balance of £38,743. The sum of £1,667 has been provided for income tax, £25,000 has been transferred to the general reserve fund, and an interim dividend of 2 per cent., absorbing £4,662, was paid on Dec. 1 last. The directors recommend a final dividend of 2½ per cent., making 4½ per cent. for the year, the balance of £1,676 being carried forward. The liability of the Company to maintain certain cables on the West Coast of Africa, in accordance with the arrangement entered into with the French Government, dated Feb. 10, 1902, expired in September, 1904.

## WEST INDIA AND PANAMA TELEGRAPH.

The report for the half-year ended Dec. 31, 1904, states that the amount to credit of revenue is £27,135, against £32,399 for the corresponding half of 1903. Expenses have been £21,422, against £25,245, leaving a balance of £5,714, to which is added £1,838, interest on investments and £1,583 brought from last account, making a total of £9,135. It is proposed to pay a dividend of 5s. per share on account of arrears to Dec. 31, 1904, on the first preference shares, and to carry forward £494. This will leave the following dividends in arrear: on the first preference shares, £3,456, and on the second preference shares £12,605. Expenses of repairing cables during the half-year were £10,424, against which the sum of £4,050 has been received for the charter of the Company's repairing steamer "Henry Holmes." These expenses are, however, exclusive of a further expenditure of £3,446, which has been charged to reserve, in respect of 40 knots of new cable used in the repair and partial

Digitized by Google

renewal of the two cables between Jamaica and Porto Rico. Instead of the expected improvement in the Company's traffic receipts, there has been a decrease during the half-year of £1,862, as compared with the corresponding period, and those for the current half-year also show a decline. In December a contract was entered into with the Telegraph Construction and Maintenance Company for the manufacture of 215 knots of cable for stock, which have since been delivered in the West Indies. Owing to continued ill-health, Mr. Andrews has resigned his seat at the Board. Mr. Le Rougetel having terminated his connection with the International Ocean Telegraph Company resigned his position as their nominee on the Board of this Company. The International Company nominated Mr. Tom Waldemar Goulding as a director in his place, and he has been elected to a seat at the Board.

## APPOINTMENTS VACANT.

**General Manager,** Johannesburg, £2,000; Station Engineer, £1,000, with house. Applications to Mordey and Dawbarn, 82, Victoria-street, Westminster.

**Tramways Manager,** Erith. Salary, £250 per annum. Applications by May 27. See advertisement in last issue.

**Chief Assistant Electrical Engineer,** Battersea Borough Council. Commencing salary, £200 per annum. Applications by noon on June 6. See advertisement in last issue.

**Assistant Borough Electrical Engineer,** Poplar. Salary, £200 per annum, rising by annual increments of £10 to a maximum of £300 per annum. Applications by June 14. See advertisement.

**Articled Improver,** Maidenhead Electricity Works. Applications efore June 9. See advertisement.

**Junior Engineer,** Dundee Electricity Department. Applications to H. Richardson, A.M.I.E.E., general manager and engineer. See advertisement.

**Jointer,** experience with electric light cables, East Sussex County Asylum, Hellingly. See advertisement.

**Director,** with £5-10,000, large electrical supply company on the Riviera. See advertisement.

**Partnerships (two).** See advertisements.

**Assistant Engineer,** Newcastle City Asylum, Gosforth. Wages, 36s. weekly and house on the estate. Applications by June 3. See advertisement.

**Switchboard Attendants (three),** North of England. Wages to commence 35s. per week of 56 hours. See advertisement.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Tonbridge.**—The Urban District Council require tenders for cables. Tenders by May 29.

**St. Marylebone.**—Tenders are invited for the annual supplies in the electricity department. Tenders by May 28.

**Copenhagen.**—Tenders are invited for supply of armoured cable. Apply to Belysningsvaesenet, Vestre boulevard 22.

**Cataquoxes (Spain).** — The local light and power company require tenders for electrical plant. Tenders by July 1.

**Edinburgh.**—Tenders are invited for extension of switchboard panel at McDonald-road electricity supply station. Tenders by May 30.

**Madrid.**—The Public Works Department require tenders for carrying out a scheme for an electric tramway for goods transport along Bilbao quays.

**Madrid.**—The Post and Telegraphs Department require tenders for construction and working of a telephone line at Matron (Balearcs). Tenders by June 5.

**Bracebridge (near Lincoln).**—Tenders are invited for the installation of fire alarms, telephones, bells, and tell-tale clocks at the Bracebridge Asylum. Tenders by June 7.

**Partick.**—The Town Council invite tenders for the supply of various plant at their electricity works. Tenders by 12 noon on June 6. See advertisement in last issue.

**Edinburgh.**—Tenders are invited for steam and exhaust pipework at McDonald-road electricity supply station. Tenders by 10 a.m. on June 6. See advertisement in last issue.

**Lirla.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Krakow.**—The Government Railway require tenders for extensions of their electric station, including additional generators, switchboards, motors, etc. Tenders by noon on May 28.

**Kettering.**—The Urban District Council invite tenders for the supply, delivery, and erection of Nernst lamps, posts, etc., for street-lighting within their district. Tenders by May 29.

**Talgarth (Wales).**—Tenders are invited for (1) wiring of the new farm buildings, including the supply and fixing of motors and (2) fire-alarm installation at the Brecon and Radnor Asylum. Tenders by June 7.

**Burslem.**—The Corporation invite tenders for wiring the town hall, markets, baths, gymnasium, and Wedgwood Institute, and also for the supply of house service fuses and meters. Tenders by May 30. See advertisement in last issue.

**Leventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Bristol.**—Tenders are invited for single-phase alternating current transformers and three-phase to direct-current motor-generators. Full particulars from the City Electrical Engineer, Temple Backs, Bristol.

**Edinburgh.**—Tenders are invited for the supply of lead sheathed, paper-insulated copper cables for electricity supply conductors for the year ending May 15, 1906. Tenders by June 5. See advertisement.

**Madrid.**—The Post and Telegraphs Department require tenders for 50 tons 4mm. zinced iron wire and 5 tons 3mm. bronze wire. The maximum price for the iron wire is 580 pesetas and that for the bronze wire 3,400 pesetas per ton. Tenders by June 5.

**Stalybridge.**—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

**Ossett (Yorks).**—The Town Council invite tenders for the following plant: (Section No. 1) quick-speed engines for direct coupling to dynamos; (2) dynamos, boosters, and balancers; (3) storage battery; (4) switchboard; (5) travelling crane; (6) cables. Tenders by June 14.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Brussels.**—Tenders are required for the maintenance of the electric lighting of the buildings belonging to the Roads and Bridges Department for the three years ending Dec. 31, 1907. Specification No. 40 may be obtained for 4d. at Brussels, Rue des Augustins, No. 15. Tenders by May 29 by a registered letter.

**Bristol.**—The Docks Committee invite tenders for the construction, delivery, erecting in place, fitting, testing, and maintenance for 12 months after completion, of four two-ton movable electric jib cranes, and one three-ton movable electric jib crane to be erected on the adjoining wharf at Canons Marsh. Tenders by June 7.

**Bangour (Scotland).**—The District Lunacy Board invite tenders for the following works: (1) building in boiler economisers, etc.; (2) building in chimney stalk; (3) building in steam and electric cable trenches; (4) steam boilers; (5) engines and dynamos; (6) economisers and piping; (7) overhead travelling cranes; (8) accumulators; (9) switchboard and connections; (10) main cables and branches. Tenders by May 27.

**Hammersmith.**—The Council are about to supply all electricity to the stands at the Olympia Electrical Exhibition, and invite propositions from bona fide British manufacturers for the hire of the necessary materials for the distribution inside the hall. The materials required will consist of (A) meters; (B) lead-covered and armoured cables; (C) distribution pillars; (D) fuse and switch boxes for exhibitors' stands; (E) continuous-current plant (motor-generators, rotary converters, or steam driven). Tenders by June 2. See advertisement.

## RESULTS OF TENDERS.

**Electric Fans.**—Messrs. W. H. Allen, Son, and Co., Bedford, have obtained the contract for a large number of fans driven by electric motors which are to be installed in the engine-rooms and lower parts of the battleships and cruisers which are now being built.

**Hull.**—The Trustees of the William-street Primitive Methodist Chapel have received the following tenders for lighting premises by electricity:

| | | | |
|---|---|---|---|
| King and Co., Hull | £151 | 7 | 6 |
| E. M. Parsons, Hull | 124 | 0 | 0 |
| A. Shaw, Hull (accepted) | 145 | 10 | 6 |
| T. Stather and Co., Hull | 134 | 0 | 0 |
| Harrison and Co., Hull | 158 | 12 | 6 |
| A. Smith, Bridlington | 94 | 0 | 0 |
| J. H. Nicholson, Hull | 108 | 0 | 0 |
| Wright and Fillingham, Hull | 75 | 15 | 8 |
| A. Innes, Leeds | 114 | 18 | 6 |
| H. Hyde, Hull | 118 | 5 | 0 |
| R. J. Nicholson and Co., Manchester | 130 | 4 | 7 |
| C. Wokes and Co., Hull | 123 | 17 | 0 |
| H. H. Butterfield, Leeds | 251 | 14 | 0 |

**Devonport.**—The following tenders have been received for the supply of one surface condenser with electrically-driven pumps for the Electricity Department:

| | |
|---|---|
| Summers and Scott, Limited | £1,090 |
| Mirrlees, Watson, and Co. (accepted) | 1,105 |
| Cole, Marchent, and Morley | 1,158 |
| I. Storey and Son | 1,215 |
| Masson and Scott and Co., Limited | 1,250 |
| Brush Electrical Engineering Company | 1,261 |
| J. Wright and Co. | 1,271 |
| Willans and Robinson | 1,304 |
| Richardsons and Westgarth | 1,320 |
| Worthington Pump Company | 1,354 |
| Bertrams, Limited | 1,356 |
| Balcke and Co. | 1,394 |
| W. H. Allen and Son | 1,387 |
| Carrick and Wardle | 1,485 |
| Browett-Lindley | 1,500 |
| Bellis and Morcom | 1,535 |
| Mather and Platt | 1,620 |
| Haste Pump and Co. | 1,750 |
| Wheeler Condensing Engineering Company | 2,091 |
| Hayward-Tyler and Co. | 2,142 |

Digitized by Google

**Bury.**—The Guardians have accepted the tender of F. W. Smith and Co., Salford, for wiring, at £330; and that of Messrs. Ashworth and Parker, Bury, for the electric plant, at £1,090.

**London County Council.**—The following tenders have been received (1) for the supply of 750 000 stoneware ducts required for the electric cables in connection with the reconstruction for electrical traction of portions of the Council's existing tramways, and for the construction of various authorised tramways:

| | | | |
|---|---|---|---|
| G. Skey and Co., Limited, London | £9,481 | 5 | 0 |
| Stanley Bros., Limited, Nuneaton | 10,250 | 0 | 0 |
| Stourbridge Glazed Brick and Fireclay Company, Limited, Dudley (250,000 ducts only) | 3,791 | 13 | 4 |
| J. Knowles and Co., London | 11,437 | 10 | 0 |
| H. R. Mansfield, Burton-on-Trent | 11 437 | 10 | 0 |
| H. Tugby and Co., Limited, Ashby-de-la-Zouch | 11,437 | 10 | 0 |
| T. Wragge and Son, Limited, Swadlincote, Derbyshire | 11,437 | 10 | 0 |
| Sutton and Co., Ashby-de-la-Zouch | 12 875 | 0 | 0 |
| Ingham's Firebrick Company, Dewsbury | 12,987 | 10 | 0 |
| J. F. Cummings and Co., London | 13 193 | 15 | 0 |
| Naylor Bros., Huddersfield | 16 250 | 0 | 0 |
| J. J. Lee, Crumpsall, Manchester | 18,500 | 0 | 0 |

It is recommended that the respective tenders (*a*) of G. Skey and Co., Limited, for the supply in connection with the reconstruction of portions of the London County Council tramways and the construction of various authorised tramways of 500,000 stoneware ducts for the sum of £6,287. 10s., and (*b*) of Stanley Bros., Limited, for the supply of 250,000 ducts for the sum of £3,450, be accepted.

(2) For the supply, delivery, and erection of the three 10 ton overhead travelling hand cranes required for use at the Streatham, Battersea, and Wandsworth sub-stations:

| | | | |
|---|---|---|---|
| Herbert, Morris, and Bastert, Limited, Loughborough (not to specification) | £477 | 8 | 0 |
| Jessop and Appleby Bros. (Leicester and London), Limited, Leicester (not to specification) | 620 | 0 | 0 |
| J. Gibb and Co., Limited, London | 664 | 0 | 0 |
| Carrick and Ritchie, Edinburgh* | 678 | 0 | 0 |
| J. Carrick and Sons, Limited, Edinburgh | 680 | 0 | 0 |
| Ditto (alternative) | 761 | 0 | 0 |
| J. Smith (Keighley), Limited, Keighley | 699 | 0 | 0 |
| Holt and Willett, Cradley Heath | 725 | 0 | 0 |
| Rodgers and Kaye, Bradford | 740 | 0 | 0 |
| J. Hitchen and Son, Limited, Halifax | 760 | 0 | 0 |
| Ditto (alternative) | 775 | 0 | 0 |
| C. and A. Musker (1901), Limited, Liverpool | 810 | 0 | 0 |
| Tangyes Limited, Birmingham | 871 | 0 | 0 |
| Ransomes and Rapier, Limited, London | 909 | 0 | 0 |
| J. Spencer and Co., Hollinwood, Lancashire | 915 | 0 | 0 |
| Pickerings, Limited, Stockton-on-Tees | 927 | 10 | 0 |
| J. M. Henderson and Co., Aberdeen | 980 | 0 | 0 |
| J. Booth and Bros., Limited, Leeds | 990 | 0 | 0 |
| T. Larmuth and Co., Salford | 1,025 | 0 | 0 |
| Leeds Engineering and Hydraulic Company, Limited, Leeds | 1,085 | 0 | 0 |
| T. Smith and Son, Leeds | 1,128 | 0 | 0 |
| Flavell and Churchill, London | 1,150 | 0 | 0 |
| Steel Rope Pulley Block Company, Limited, Sheffield | 1,192 | 0 | 0 |
| Rawlinsons Limited, Leeds | 1,225 | 0 | 0 |
| Parsons (Brierley Hill) Limited, Brierley Hill, Staffs | 1,275 | 0 | 0 |
| Cowans, Sheldon, and Co., Limited, Carlisle | 1,290 | 0 | 0 |
| Dougill's Engineering, Limited, Leeds | 1 770 | 0 | 0 |
| Butter Bros. and Co., Glasgow | 2,335 | 0 | 0 |

* Recommended for acceptance.

(3) For the supply, delivery, erection, and maintenance of the accumulators required for use at the Greenwich electricity generating station:

Supply, delivery, and erection.

| | | | |
|---|---|---|---|
| Tudor Accumulator Company, Limited, London | £1 875 | 12 | 0 |
| British Accumulator Company, Limited, London | 1 947 | 10 | 0 |
| Electrical Power Storage Company, Limited, London | 2 105 | 18 | 0 |
| D.P. Battery Company, Limited, London | 2,173 | 0 | 8 |
| Chloride Electrical Storage Company, Limited, Manchester | 2 177 | 0 | 0 |
| Accumulator Industries, Limited, Woking | 2,371 | 2 | 4 |
| A.B.P. Accumulator Company, Limited, Stockton-on-Tees | 2 755 | 11 | 0 |
| Hart Accumulator Company, Limited, London | 3,447 | 6 | 0 |

Maintenance.

| | | | |
|---|---|---|---|
| Tudor Accumulator Company, Limited | 1,120 | 0 | 0 |
| British Accumulator Company, Limited | 1,200 | 0 | 0 |
| Electrical Power Storage Company, Limited | 900 | 0 | 0 |
| D.P. Battery Company, Limited | 1,300 | 0 | 0 |
| Chloride Electrical Storage Company, Limited | 1,170 | 0 | 0 |
| Accumulator Industries, Limited | 1 045 | 0 | 0 |
| A.B.P. Accumulator Company, Limited | 2,000 | 0 | 0 |
| Hart Accumulator Company, Limited | 2,858 | 10 | 0 |

It is recommended that the tender of the Tudor Accumulator Company, Limited, amounting to £1,875. 12s. for the supply, delivery, and erection, and £1,120 for the maintenance during a period of 10 years, of the battery of accumulators required for use at the Greenwich electricity generating station, be accepted.

---

**Outing.**—The second annual picnic of the St. Annes-on-the-Sea electricity department took place on May 16. The chairman of the Council (Mr. G. W. Spring) and the chief engineer (Mr. J. H. Clothier) accompanied the party to Ingleton, where a most enjoyable day was spent. Mr. J. C. Fairchild, assistant engineer, made excellent provision for the comfort and enjoyment of those present.

# BUSINESS NOTES.

## TRACTION.

**Erith.**—The tramways are expected to be completed by July 1.

**Kirkcaldy-Leven.**—This line is expected to be in operation by next spring.

**Guildford.**—The Board of Trade have confirmed the order for a tramway between Guildford Station and Stoughton.

**Leith.**—The drivers and conductors employed in connection with Leith tramways have been officially inspected by members of the Corporation.

**Great Northern, Piccadilly, and Brompton Railway.**—In the House of Commons on Wednesday the Great Northern, Piccadilly, and Brompton Railway (No. 1) Bill was read a third time.

**Reading.**—The Corporation have approved the annual report of the tramways manager (Mr. Binns), and have adopted his recommendation that the surplus of £3,542 be used for the creation of a reserve fund.

**Leicester.**—The Belgrave-road and Stoneygate routes have just attained their anniversary as electrified lines. During the year there have been carried on the whole system, all of which is now electrified, 20,915,085 passengers.

**Dalkeith.**—Terms of agreement between the Edinburgh Suburban Electric Tramways, Limited, and the Town Council have been settled. There will be a 15-minute service, and the through fare from the Edinburgh city boundary to Dalkeith will not exceed 4d., and the charge between Dalkeith and Eskbank will not be more than 1d.

**Cardiff.**—As one of the Corporation cars was proceeding along Working-street last week the overhead wire snapped. No accidents occurred, though the conductor had a rather narrow escape. He was standing at the rear end of the upper deck, when the wire struck him on the shoulder and then fell into the roadway, but he escaped without injury of any kind.

**Live Rails.**—It is reported that the electrified section of the Lancashire and Yorkshire Railway between Liverpool and Southport is being metalled with a very hard, marble-like stone which offers great resistance to the passage of electricity. This non-conducting ballast, which, it is stated, will withstand a current of 3,000 volts without penetration, is spread in a thin layer underneath and between the sleepers. It has already been adopted on the North-Eastern Railway Company's electrified lines.

**Tramcars and Railways.**—In consequence of the increasing competition of the Bradford Corporation tramways, the Midland Railway Company has asked for an abatement in the assessment of its lines within the city. The committee has offered a reduction of £3,000, which will mean a loss to the Corporation revenue of £1 250. The takings of the Bradford city tramways for 12 months ended March 25 show an increase over the preceding year of £31,363, only part of which is attributed to the Bradford Exhibition.

**Aberavon.**—A Bill to confirm a provisional order authorising the Aberavon District Tramways Syndicate, Limited, to construct tramways in the borough of Aberavon came before the Examiners of the House of Lords for proof of compliance with the Standing Orders. There was no opposition at this stage, and the necessary formal proofs having been given, the Examiner certified that the Standing Orders had been duly complied with. The Bill will accordingly, in the usual course, be reported for second reading.

**New Paper.**—We have received No. 1 of the *Tramway and Vehicle Worker* (price 1d.), a weekly paper devoted to tramway, motor, and vehicle work. It is to be the official organ of the Amalgamated Association of Tramway and Vehicle Workers' Union. There will be a leader in each issue upon passing tramway and vehicle topics, descriptions of different firms' equipments, instructive paragraphs, and other features. The first number is excellently composed, and in providing motormen with a medium of instruction and information it should have a distinct sphere.

**Paris Tube Railway.**—The new Paris railway company, known as the "Tube Boulevard," which will run from the Porte Saint Ouen to Versailles, has just increased its capital in consequence of the promulgation of the law granting the concession. The length of the line will be about eight miles. The municipal rates payable to the city of Paris will be 1c. (about one-tenth of a penny) per second-class ticket for the first 30 million tickets sold, 2c. per ticket beyond that number, and 25c. on every first-class ticket. The concession is for 35 years. The cost of construction is estimated at about £3 000,000.

**Greenock.**—The negotiations between the Corporation and the company regarding the supply of energy have now been completed, and an agreement for the next five years has been signed by Lord Emlyn, chairman of the company, and Provost Denholm. The agreement is for five years, during which time the company will take from the Corporation all the energy needed for the tramways. The company guarantees a minimum annual consumption of 500 000 units, and the rates are as follows: first 500,000 units per annum 1·5d. per unit; next 200,000 units per annum, 1·25d. per unit; next 200 000 units per annum, 1·00d. per unit; all units consumed per annum in excess of 900,000 units, 0·85d. per unit.

**Dundee.**—The tramway manager has submitted to the Tramway Committee a statement of the charges he proposes for the carriage of parcels. His scheme is as follows: collections to be at intervals from business houses as might be arranged; conductors to accept parcels at any of the fixed stopping places *en route*, for delivery in any part of the city; appointment of agents in convenient parts of the city; issue of weekly tickets for the carriage of dinner and other baskets. The scale is: up to 7lb., 1d.; up to 14lb., 2lb.; up to 28lb., 3d. Dinner baskets, one parcel per day, 3d. per week, and special terms for traders with 50 parcels or over per week. The proposals were agreed to,

Digitized by Google

Attention was drawn to the damage done to the permanent way of the tramways in Ferry-road between Craigie-terrace and Springhill by traction engine traffic. The burgh engineer was instructed to go over the road and submit a report.

**Wednesbury.**—At the meeting of the Town Council the Mayor moved that the Council approve an agreement with the South Staffordshire Tramway Company for the purchase of the tramway undertaking in the borough, including the depôt, offices, and machinery at King's Hill, but excluding any portion of the line between James Bridge and Darlaston, for £23,920. He explained that of this £11,500 represented the price of the depôt which was to be resold, and the balance would be repayable in 30 years, the tramway company reimbursing both principal and interest. A promise had been given that the reconstruction and electrical equipment of the Darlaston line should be undertaken forthwith, and when this had been carried out measures could be taken for the reopening of the Dudley section. The motion was agreed to, as was a further resolution authorising the sale of the depôt to the tramway lessee company.

**Batley.**—The electrification of the old Bradford-road tramway is now to be undertaken. Everything is in readiness in regard to the arrangements between the company and the local authorities. The Tramways Committee have decided to accept the tender of Messrs. Dick, Kerr, and Co. for the laying of the rails and the erection of the overhead wires, the Corporation undertaking the paving of the track. The project comprises the equipment of a double line from the junction with the other electric routes in Dewsbury Market-place to Birstall, and thence a single line to the junction at Birkenshaw. It is proposed to undertake the Dewsbury-to-Batley section first, and to keep the old engines and cars plying from Hick-lane to Birstall until that is finished. It is hoped that the Dewsbury-Batley section will be ready for opening by the end of July. The rest of the track will occupy another month or six weeks, and the early autumn should see the completion of the system. The Board of Trade only extended the present running powers by steam for six months, that period expiring on Aug. 21.

**Belfast.**—At the meeting of the Tramways Committee on Monday a deputation attended in support of an extension of the Stransmillis-road line. As the Corporation possess no powers for this at present, it was decided to defer the matter. Mr. M'Cowen, electrical engineer, submitted the following report on the question of overhead telephone wires: "I strongly recommend the removal of all overhead telephone wires on the tramway routes within the city, where possible. The existence of other wires above the trolley wires is always a possible source of danger, and even though protected by guard wires, the adoption of the latter is not desirable, as they are often the cause of accidents and trouble. With reference to isolated cases of telephone wires crossing the trolley wires in outlying districts, I have already reported on this matter on March 27 last. The insulated cables which the Telephone Company proposed to erect in such cases would be about ¾in. in diameter." The report was adopted by the committee, who considered that they should not take any risk in regard to this important matter. Reports on the progress of the different works were presented. The general manager reported that the whole of the car equipments and car trucks could be had at any time, while of the car bodies 22 were already dispatched from the works, 16 were in the paint shops, 52 were in progress in the car-building shop, and the remaining 80 would all be started before the middle of June. The Brush Company expected to have the 170 cars in Belfast, and completely finished and fitted on their trucks, on or before Aug. 1. The work at the Knock and Falls depôts was finished; at the Sandy-row, Antrim-road, and Mountpottinger depôts the work was well in hand; and he hoped to commence work at the Shore-road depôt by the end of May. The city surveyor reported that up to the present good progress had been made with the generating station, and that no delay had been occasioned to other contractors. In regard to permanent way, he reported that the amount of new work to be done reduced to single track was 60 miles, and the lines to be bonded and repaired 16 miles. The work has now been going on for nearly four months, and the equivalent of 20 miles of new work single track has been completed, and two miles single track bonded and repaired. The rate of progress during the last month or six weeks has been considerably greater than during the first two months of construction. Feeder cables have been laid on the Antrim road, Ligoniel and Crumlin roads, Springfield-road, Falls-road, Shore-road, and Shankill-road to a total length of 6 miles 570 yards. The total length of route feeder cables to be laid is 33 miles. In order to carry out the training of the drivers, it was decided to purchase a quantity of generating plant at a cost not to exceed £900, most of this plant being afterwards available when the electric tramcars are running. Mr. M'Cowen explained that he had written to 17 firms on this subject, and that he had now a great deal of information which would assist them in the future. Mr. Nance stated that the teaching of the 236 men would cost close on £2,000, but, in his opinion, this was the only way in which the work could be satisfactorily done. Terms have been agreed with the British Electric Traction Company for supplying current for the Cavehill and Whitewell lines.

**London County Council.**—At Tuesday's meeting of the Council the Highways Committee submitted a recommendation that an expenditure of £5,513 be authorised for constructing the tramways in Archway-road, Highgate, between the Archway Tavern and the county boundary at Highgate Archway. It was also recommended that an agreement be entered into between the Council and the County Council of Middlesex and the Metropolitan Electric Tramways, Limited, embodying the following terms: that the Council shall construct, at its own expense, a double line of tramways in Archway-road, Highgate, between the Archway Tavern and the county boundary at Highgate Archway, to link up with the light railways of the County Council of Middlesex at the county boundary; that the Council shall provide the necessary overhead equipment for the lines; that the tramways shall be leased by the Council to the Metropolitan Electric Tramways, Limited, with the consent of the County Council of Middlesex, for a period of three years; that the lessees shall covenant to repair and maintain, and if necessary to renew, the lines and overhead equipment to the satisfaction of the Council; that the rent to be paid to the Council in respect of the tramways shall be at the rate of £1,500 for the first year, £2,000 for the second year, and £2,500 for the third year; that the paving of the tramway tracks shall be of such a material as may be agreed upon between the Council and the County Council of Middlesex; and that the rolling-stock and the electrical power necessary for working the tramways shall be provided by the Metropolitan Electric Tramways, Limited. These recommendations were confirmed. Another recommendation was that an expenditure of £7,750 be sanctioned for land to form part of the site of the Pimlico generating station. The receipts for the week ended May 13 totalled £14,812, against £10,588 last year, the mileage being 291,222 and 230,054 respectively. The Council's scheme for running tramways across Westminster and Blackfriars Bridges and along the Victoria-embankment came before a Select Committee of the House of Commons last week. Mr. Kearley was the chairman. The opponents to the Bill are the City Corporation, the Metropolitan District Railway Company, the owners and occupiers of property having a frontage to the Embankment, and the Lambeth Borough Council. Mr. Pollock, K.C., for the promoters, said that up to the present there was no means of communication between the northern and southern systems, and it was this want the Bill sought to fill. The new tramways were to be constructed on the conduit system, and the first section would begin at the tramway terminus at Westminster Bridge, cross the bridge, and continue along the Embankment to the subway at Waterloo Bridge, where there would be the terminus of the northern tramway coming from underneath the Strand. A small section would also be constructed to link up the Albert-embankment line. The two sections, the first of which would be one mile and four chains in length, would cost £53,700. The next section, which would be seven furlongs long, would run from the subway along the remainder of the Embankment over Blackfriars Bridge, and make a junction with the existing system there. This would cost £52,700. On each side of the tramway lines on the Embankment there would be a clear space for other traffic of 25ft. Dealing with the necessity for the new lines, counsel said an enormous boon would be conferred on the working classes, a point which could not be better illustrated than by the fact that 21 borough councils out of 28 had passed resolutions in favour of the scheme. Every single borough which would be coupled up was supporting it, except Westminster, which was not opposing the scheme, but which had not passed a resolution in favour of it. The new line would relieve the troublesome and dangerous congestion at Westminster and Blackfriars, the extent of which might be realised by the fact that in one year the cars running to Westminster brought in 53,000,000 passengers, and those running to Blackfriars no fewer than 38,000,000. Coming to the petitions against the Bill, Mr. Pollock described that from the City as a dog-in-the-manger petition. The Metropolitan District Railway were, naturally, in opposition, but the answer to their petition was that these tramways would deposit more passengers at the District Railway stations than they would take away. Counsel then proceeded to read a letter from the Home Office, transmitting another letter from the Chief Commissioner of Police, dealing with the possible effect of the scheme on the general traffic, especially in the neighbourhood of the Houses of Parliament. The Chief Commissioner pointed out that while there was ample room on Westminster Bridge and Victoria-embankment, congestion even now occurred in Bridge-street because of the heavy traffic coming across the bridge, and it was felt that cars from the south turning into the Embankment would cut through the main stream of traffic going in the opposite direction, and thus increase the congestion. Mr. Pollock's reply was that as an electric car would turn the corner quicker than a hansom cab, there was little probability of aiding to the congestion. Mr. Fitzmaurice, the engineer-in-chief to the London County Council, was the first witness examined. He mentioned that there would be a space of over 17ft. between the car lines and the kerb of Westminster Bridge, and a space of 8ft. between the two sets of tramway lines. Sir Ralph Littler suggested to witness that the blocking of the traffic on the south side of the bridge in question might be obviated by the Council buying up some of the houses there and making a "station" terminus. Mr. Fitzmaurice replied that the Council did not want a "station terminus." What they wanted, and what the public wanted, was a circuit route across the bridge and along the Embankment. He stated that there would be no engineering difficulty in running over the tunnels of the Metropolitan Railway. Mr. Allan Baker, the chairman of the Highways Committee of the Council, gave evidence as to the necessity of the proposed tramways, and also as to the erection by the Council of a large generating station at Greenwich. Mr. H. E. Hayward, comptroller to the Council, said that on the estimate of 1s. per car mile, an estimate based on actual experience, there would be a gross revenue of £46,000, and the working expenses at 7d. per car mile would be £27,000. The interest and sinking fund charges would be £10,500, and the renewals, at 1½d. per car mile, £5,700. The surplus for the first year would thus be £2,800, and this would increase as the debt was paid off. Mr. Harper, statistical officer to the Council, gave evidence as to the vehicular and pedestrian traffic along the proposed route. The result of his calculations was that the omnibus service over the bridges was totally inadequate in the busy hours. Observation showed that the tramway termini at Westminster and Blackfriars were not the natural termini. Mr J. K. Bruce, traffic manager of the Council's tramway service, stated that it was proposed to run a one-minute service over the bridges. The scheme would mean a saving of 15 minutes in the journey from Westminster to Islington. He attached great importance to the facilities the route would give for through north and south traffic. Mr. A. Baker, general manager of the Birmingham tramways, formerly manager for the London County Council,

Digitized by Google

gave similar evidence, and expressed the opinion that the continuance of the tramways over the bridges was really the only solution of the London traffic problem. Mr. J. R. Tompkins, Mayor of Camberwell, Mr. T. White, Mayor of Lewisham, and Mr. H. R. Barge, member of the Poplar Borough Council, also gave evidence in favour of the Bill on behalf of their respective councils. The Chairman intimated the intention of the committee to inspect the bridges and the Embankment. On Wednesday evidence was given by Mr. A. A. Campbell Swinton, who stated that his objection to trams along the Embankment was that there was no give-and-take about vehicles running on rails. He preferred motorcars for connecting the northern and southern systems, and considered that these would be cheaper, besides causing less interference with other traffic. Mr. John Burns strongly advocated the running of trams over the bridges, on the ground that travelling facilities and the housing problem were inseparably connected. He did not think it necessary to widen Blackfriars Bridge, though, if this were done, it would probably have weight with the City Corporation. This concluded the case for the promoters, after which Mr. Baggallay opened the case for the Embankment frontagers, arguing that traffic along that thoroughfare ought to be kept for light fast traffic. Evidence was given as to the anticipated effect of the trams in depreciating property. The Streatham Tradesmen's Association have petitioned the Wandsworth Borough Council in favour of the extension of the trams from Streatham to Norbury, and the Council have decided to ask the County Council whether they propose to apply for powers for this purpose in the 1906 session.

## LIGHTING AND GENERAL.

**Barnstaple.**—The Council have decided to apply for leave to borrow £4,000 for electric light extension.

**Removals.**—Messrs. Crawford and Cumming, consulting engineers, have removed to 41, George-street, Edinburgh. Their telephone number is now 1,222 Central.

**Sale of Plant.**—For particulars of a sale of plant, comprising Crossley gas-engine, Castle dynamo, E.P.S. accumulators, switchboard, and all accessories, now running nine miles out of London, see advertisement.

**Llanelly.**—The Borough Council, on the advice of Mr. J. C. Howell, have adopted a scheme under which they will purchase electrical energy from the South Wales Power Company, and lay their own distributing mains, at an estimated cost of £6,000.

**Greenock.**—Mr. R. Bartsch, electrical engineer, in his last report, states that during the month of March the amount of electricity generated was 179,158 units, an increase of 61,461 units as compared with the corresponding month of last year.

**Camberwell.**—Notices have been received from the South Metropolitan Electric Light and Power Company of its intention to lay low-tension mains along The Avenue and Farquhar-road, and high and low tension mains along the Croxted and South Croxted roads.

**London Gazette.**—The first meeting in the estate of Alexander Holland, electrical engineer, trading as the Electrical and Mechanical Engineering Company, 13, Bridgwater-street, Farnworth, Lancs., will be held at 19, Exchange-street, Bolton, on May 31 at 3 p.m. An adjudication order has been made out in the estate of Harry John Salter, electrical engineer, 235, High Holborn, London.

**Stock Exchange.**—The Stock Exchange Committee have appointed May 31 a special settling day for Charing Cross, Euston, and Hampstead Railway Company Speyer Bros.' scrip certificates (fully and partly paid) for £800,000 4 per cent. perpetual debenture stock, and Great Northern, Piccadilly, and Brompton Railway Company Speyer Bros.' scrip certificates (fully and partly paid) for £1,200,000 4 per cent. perpetual debenture stock.

**Dewsbury.**—An enquiry has been held into the Town Council's application for power to borrow £10,000 to enable them further to develop their electricity undertaking. During the evidence it was stated that while in 1901 there was a loss on the works of £266, and in the year following one of £378, there had been profits made as under—viz., 1902-3, £286; 1903-4, £1,961; and 1904-5, £1,244. The demand for current was still constantly increasing.

**Bury.**—The profit on the past year's working of the Council's electricity department was £2,931, and it was decided to allocate £1,589 to the relief of general rates, and to carry £1,342 to the credit of the depreciation and reserve fund. In view of the profit made, the application for powers to borrow £400 in connection with the tripling of the engines will be withdrawn. It has been decided to extend the mains to Chesham, and a sub-committee has been appointed to deal with the charges for current for the present year.

**Stafford.**—The promoters of the Shropshire and Worcestershire Electric Power Bill having accepted the clause submitted to them for the protection of the county main roads and bridges, the County Council's petition has been withdrawn. The Parliamentary Sub-Committee have reported that in their opinion the County Council ought to support the Seisdon Rural District Council in obtaining a clause providing that the company should supply electric energy upon reasonable terms within the rural district.

**Glasgow.**—The Corporation have entered into an agreement with the Magneta Company, under which a trial installation of that system of clocks is to be erected in the Bridgeton district of the city. They have also received a letter from Messrs. Barr and Stroud with regard to the Becker system of electric clocks. Mr. Macfee, the manager of the telephone department, and a member of the Bazaar Sub-Committee are to make enquiries and report as to the Normal Zeit system of clocks which is in operation in Berlin and Brussels.

**Briton Ferry.**—An enquiry has been held into the application of the Council for sanction to borrow £3,534 for the purpose of lighting their compulsory area with electric light. The deputy-clerk, Mr. H. H. Ellis, said that the Council proposed to purchase current in bulk from the South Wales Electrical Distribution Company, the agreement being for 30 years, which, at the option of the Council, could be determined at the end of each five years. Mr. Herbert Lewis (Messrs. Lewis and Fletcher, Cardiff), electrical engineer, stated that the estimated expenditure was £761 and the receipts £762 per annum, and that he was satisfied with the agreement.

**Wellingborough.**—With regard to the agreements with the electric light companies of 1900 and 1902, it has been resolved to obtain the services of an electrical engineer to advise on the whole question as to whether the Council would be justified in putting down plant and undertaking the public lighting by means of refuse destruction only, and as to the capital and annual cost thereof. The Council will also ask the County of Northampton Electric Power and Traction Company to make suggestions and submit an estimate of cost of lighting the streets, including the taking over by them of the working of the refuse destructor in an efficient manner under conditions to be approved by the Council.

**Turbines.**—At the fourth annual meeting of shareholders in J. I. Thornycroft and Co. it was stated that, anticipating that the Admiralty would require all the new torpedo-boats and destroyers fitted with turbine machinery, the directors had concluded an agreement with the Parsons Marine Steam-Turbine Company by which they were empowered to manufacture turbines on the payment of royalties. A scheme had been prepared for the purchase of plant and the erection at Southampton of the necessary buildings with all possible speed. Since the report and accounts had been circulated an order had been received from the Admiralty for five coast-line torpedo-boat destroyers fitted with turbine machinery.

**Fulham.**—From April 28 to May 11, 1905, 13 consumers with 330 8-c.p. lamps were added, making a total of 1,477, with an equivalent of 74 336 8 c.p. In settling the new scale of charge for the supply of electric current for private lighting, the reduction in price was made subject to a minimum charge of £2 per annum. Objection has been raised by consumers, and it is felt that the condition is likely to cause disputes and friction. To enforce the proposal would necessitate a very considerable expense and trouble in the preparation and stamping of new forms of agreement, and in consequence it is proposed that the minimum charge of £2 per annum to consumers of electric current for private lighting purposes be waived.

**St Pancras.**—Messrs. Idris and Co., Limited, having complained of noise from the King's-road works since the new turbine has been working, the chief electrical engineer forthwith took steps to stop the noise complained of by having the large windows facing Messrs. Idris and Co.'s premises bricked up. A sub-committee subsequently visited the station whilst the whole of the plant, including the turbine, was running, and afterwards proceeded to the Board-room at Messrs. Idris's, the windows of which were opened, and no noise whatever could be heard coming from the King's-road station. The directors have since stated that they had now no reason to complain of the noise, and have thanked the committee for dealing so promptly with the matter.

**London County Council.**—On Tuesday it was agreed to lend the Woolwich Borough Council £9,267 for electric lighting purposes. Notices under Electric Lighting Acts and Orders were agreed to as follows: from the Notting Hill Electric Lighting Company of intention to lay mains along a portion of Clarendon-road; from the St. James's and Pall Mall Electric Light Company to lay mains along portions of Regent-street, Vigo street, Sherwood-street, and Glasshouse-street; and from the St. Pancras Metropolitan Borough Council to lay mains across Cardington-street and along portions of Ampton-street and Pakenham-street. The receipt of notices, as follows, served under orders granted to local authorities, and under which the Council has no power of approval or disapproval of works, was acknowledged from the St. Marylebone Metropolitan Borough Council to lay mains along a portion of Edgware-road, and from the Stepney Metropolitan Borough Council to lay mains across Bridge-street and along Emmott-street and a portion of Commodore-street.

**London Wiring.**—The two clauses in the General Powers Bill of the London County Council which empower borough councils having electricity undertakings to wire and fit, and supply with wires, fittings, motors, and apparatus, the premises of their consumers or prospective consumers, and to borrow money for this purpose, were passed by a committee of the House of Commons on Wednesday. The metropolitan gas companies objected on the ground of rate-aided competition, and the Association of Electrical Engineers and Contractors asked that the borough councils should be restrained from carrying out this wiring and fitting except through contractors. A proviso had been introduced for the protection of the gas companies, providing that, "so far as reasonably practicable," the councils should so adjust the charges to be made by them as to meet any expenditure on the fittings. It was also provided that the councils should only supply, and not manufacture, these fittings or apparatus. The Chairman said the committee had always insisted on the form "power to supply," but not to manufacture. The qualifying phrase "so far as reasonably practicable" was struck out, in order to make it absolutely certain that no loss shall fall on the rates, and a provision for interest and sinking fund charges will be insisted upon. The committee declined to insert a clause compelling the councils to do the work through contractors.

**Watford.**—The electrical engineer in his last report states that an equivalent of 32,000 8-c.p. lamps was connected to the Council's system at March 31 last, as against 26,000 at March 31, 1904. A pit has been constructed with cement walls, 2ft. thick, to take the condensing plant. This has not been found watertight, and it was recommended that the bottom of the pit be covered with cast-iron plates, and the four sides to a height of 9in., with provision for further

Digitized by Google

extension if necessary. This clause has been deleted from the report. The electrical engineer has been empowered to fix a trial gear to the existing arc lamp columns, by means of which the lamps may be lowered by the trimmer without assistance or ladders. The cost of such equipment would be about £3. 10s. per post.

**Wakefield.**—An enquiry was held last week into the application of the Corporation to borrow a sum of £18 000 for electric lighting purposes. The Town Clerk said that the existing outstanding loans on electric lighting undertaking amounted to £49,788. It was intended only to apply for a further loan of £17,700, a sum of £300 for the proposed sub-station having been abandoned. Mr. Newell said the profits on the electric lighting undertaking were as follows: 1900 £129, 1901 £463, 1902 £187, 1903 £914, and 1904 £1,894—about two-thirds being for lighting and one-third for power. It was proposed to extend the boiler-house, the pump-house, etc.—the new plant comprising boiler, stoker, superheated water softener, two high-speed sets, condenser, switchboard, mains, and transformers.

**Yeomanry Camp Lighting.**—The superior convenience and comfort of the electric light as an illuminant for their camp has been much appreciated by the Royal Bucks Hussars I.Y., who are now undergoing their annual 17 days' training under canvas at Stowe Park, Buckingham. A portable plant placed alongside the encampment supplies current for single pendants in each officer's tent, and groups of three-light pendants in the various officers' and sergeants' mess tents, ante-rooms, canteen, etc. Some of the tents, which measure 120ft. long, are additionally illuminated by Verity's single enclosed arc lamps, which are also employed for lighting the parade ground. All the arrangements for lighting the camp were carried out by Messrs. Gillies and Hornidge, of the Buckingham Electric Light Company, London and Buckingham.

**Southend.**—The electrical engineer's last report states that during the month 34 consumers were connected to the mains, with the equivalent of 1,334 lamps. There are now 773 consumers and 48,664 lamps connected to the mains. The units generated for lighting were 60,251, compared with 38,122 for the previous year, an increase of 58 per cent. The tramway receipts for the month were £1,361, as against £1,263 for the corresponding period of last year. The rate per car mile was 10·4d., as against 9·4d. The electrical engineer also called attention to the large increase in the demand for electrical energy, which would necessitate in the near future the committee again considering the question of extensions of plant. The 4½d. flat rate system of charges for electricity, now in operation in respect to private houses, is to be extended to shops and other business premises.

**Electrical Contractors' Association.**—The annual meeting of the northern section of the Electrical Contractors' Association (Incorporated) was held at Blackpool on May 2, Mr. J. McDermott, of Ashton-under-Lyne, in the chair. The following officers were elected for the ensuing year: chairman, Mr. W. Sutton, of Liverpool; hon. treasurer, Mr. T. G. Usher, of Newcastle-on-Tyne; hon. secretary, Mr. W. Cross, 4, St. Nicholas-buildings, Newcastle-on-Tyne. The annual report, which was adopted, stated that the membership for the northern section for the year maintained a steady increase. In May, 1904, the total list of members numbered 69; during the year 12 resigned for various reasons, and 25 new members joined, making a total on May 1, 1905, of 82 members; of these new members eight were in business in Bradford and district, having joined the Leeds branch. The increasing number of applications and the greater interest shown by the trade generally gave the committee confidence that the membership would soon be over 100, and inasmuch as the incorporation only took place on Sept. 16 last, the results were very encouraging.

**Hiring Out of Electric Motors.**—We have received from Mr. Alfred H. Gibbings, M.I.E.E., A.M.I.C.E., the following interesting table showing the effect of the system first introduced by him in 1896 as supplied from the mains of the Bradford Corporation:

| Year. | Number of motors supplied from Corporation mains. Owned by consumer. Not on hire. | Owned by Corporation. On hire. | Total. | Board of Trade units sold per annum. |
|---|---|---|---|---|
| 1895 | 35 | nil | 35 | 35,989 |
| 1896 | 58 | 7 | 65 | 54 972 |
| 1897 | 72 | 46 | 118 | 117,176 |
| 1898 | 99 | 122 | 221 | 205 243 |
| 1899 | 152 | 259 | 411 | 465,630 |
| 1900 | 204 | 405 | 609 | 933 455 |
| 1901 | 229 | 525 | 754 | 1,297,120 |
| 1902 | 272 | 641 | 913 | 1,900 534 |
| 1903 | 297 | 670 | 967 | 2,008,294 |
| 1904 | 451 | 716 | 1,167 | 2,704,663 |

**Burton.**—With regard to the balance-sheet of the electricity department, which appears in another issue, Mr. Pringle, the borough electrical engineer and tramways manager, writes as follows: "During the year we have introduced an alternative 5d. flat rate for lighting, which has meant that about two-thirds of our consumers who got no rebate on the maximum demand system have had their price reduced from 6d. per unit to 5d. per unit. In addition, we are now giving our rebates for lighting quarterly instead of half-yearly, so that during the quarter March, 1905, we have advanced over £400 to our consumers, which in the ordinary course would have been held over as a rebate and given in the June quarter. Although there has been a much larger increase in the lamp connections—*i.e.*, 14·2 per cent. against 12·2 per cent. of last year—we have only had an increase of 5 per cent. in the units sold for lighting against an increase of 18·3 per cent. for last year. The trade this year has been one of the worst known in the town, and the falling off in consumption is directly attributable to this. The concessions mentioned above and the depression in trade therefore accounts for the smaller surplus this year. These adverse conditions, however, may be taken as of a temporary nature only. The progress of motor connections has been distinctly satisfactory, and with 102·5 h.p. in hand, which are about to be connected, brings up the grand total to 306·75 h.p."

**Stockport.**—An enquiry has been held into an application of the Corporation for sanction to borrow £6,125 for the purchase of electric motors for the electricity department. This is the first application made by the Council to enable them to hire out electric motors for various driving purposes. The Electrical Engineer (Mr. Carter) said that motors would range from ½ h.p. to 15 h.p., and would be used for chaff cutting, the driving of sewing machines, printing presses, ginger-beer machines, stone-cutting in connection with buildings, etc. They were now being used on the work of constructing the new town hall, and they had been asked for in connection with several new buildings in course of erection. The charge for hiring out would be 20 per cent. of the total cost of the motors for outside work, and 15 per cent. for inside work. The Town Clerk (Mr. R. Hyde) said the motors would always remain the property of the Corporation. Under the Stockport Corporation Act of 1899 they had power to purchase and hire motors and other apparatus incidental to or connected with the use of electricity. The electricity works were in a flourishing condition. Last year there was a net profit of £1,760 after providing for payment of interest and sinking fund on capital charges. On the small capital invested he considered that a high rate of interest.

**Swansea.**—The balance-sheet of the municipal telephone undertaking for the year ended March 31 shows that the revenue account has been charged with 10 per cent. depreciation on tools and 5 per cent. on office furniture, and with the whole of the cost of the issue of the four years 4 per cent. debenture bonds, amounting to £180. The whole of the rentals, trunk calls, etc., that were considered to be irrecoverable, amounting to £105, have been written off. After bringing these charges into account there remained a gross profit of £1,742, or approximately 8 per cent. upon the amount expended on construction. Carrying this gross profit to net revenue account, and charging this account with interest and sinking fund to March 31, 1905, left a net credit balance of £740. After deduction of a loss of £324, resulting from the five months' working to March 31, 1904, a sum of £416 remained. The committee will ask the Corporation to provide £7 500 for the purposes of further extending the system as required from time to time. The Corporation are being urged by the Local Government Board to provide forthwith for a sinking fund on the customary scale as from the beginning of their electricity undertaking. Although the department is now earning money every year, the sums retained in a suspense account, representing balances credited to the station during the last two years, will now be entirely swallowed up, and the electric lighting accounts for this year will probably show a deficit besides of between £1,500 and £2,000.

**Hastings.**—An application from the Postmaster-General for consent to the placing of an overground telegraphic line along the side of certain public roads has been acceded to. The Council ask that the poles should be of a suitable character and painted green. The Railways and Tramways Committee have agreed to a letter in which Messrs. Kincaid, Waller, and Co. stated, in connection with the conditions imposed by the Council upon approving of the drawings of the proposed feeder system for the supply of electrical energy for the tramways, that they intend that all joints on the three-phase high-tension feeders shall be made in cast-iron boxes under the roadway or footway, and filled in completely with insulating composition; that with this arrangement there is practically no more danger of failure at the joints than at any other portion of the main, but that for the purpose of locating a fault in the cable, which should be a matter of very rare occurrence, they are proposing brick inspection boxes with frames and covers at intervals of about a mile, and in their view this should enable them to locate the position of any fault very closely. The average length of the high-tension cables would be about a quarter of a mile, so that if inspection chambers were to be put at every joint, four to the mile would be required, instead of one to the mile, which they propose. The engineers further affirm that there is no intention whatever on the part of the company to supply electrical energy for any purpose otherwise than for the purpose of the tramway undertaking, and point out that the company's powers would not permit them to so enter into competition with the Corporation for the supply of electrical energy for lighting or power purposes unconnected with the tramways, so that, therefore, this question would not arise in connection with the application they have made under the Act of 1900.

**Bradford.**—The Electricity Committee have approved a report by Mr. A. S. Blackburn, the electrical engineer, on extensions of mains. The cost of the general supply mains to date has been £180,000, and the annual capital costs including depreciation at 1 per cent., amount to approximately £13,800, and for this mains having a capacity of 4,000 kw. have been provided. The engineer estimates the cost of the extensions at £37,500, and the annual capital costs, including depreciation, at 1 per cent., at £2,875, and for this an additional capacity of 2,500 kw. would be obtained. Against this a saving of £1,472 per annum is anticipated owing to increased efficiency of distribution, which would reduce the annual cost of extensions to £1,403. The engineer considers that the economy of carrying out the work simultaneously with the extension of the tramways distributive system will be very great both in cost and as regards the inconvenience of interfering with the busy streets in the centre of the city, and the whole of the work proposed by the scheme will necessitate the opening of 3,790 yards of streets. The engineer has gone into the question of the feasibility of providing a subway between certain points in which the whole of the electricity mains between the town and the works could be accommodated, and the future opening of this part of the route avoided. It was, however, found that the cost would be prohibitive on account of the many obstacles which have to be contended with in the way of gas and water pipes, the beck, sewers, and storm overflows, the latter being especially troublesome. Furthermore, the nature of the soil along the

Digitized by Google

valley is such as to necessitate special precautions to render the subway dry. It is proposed to lay 24 ducts embedded in concrete under the town hall to meet present and future demands. It is also proposed to lay the cables considerably deeper than formerly, about 3ft. to 3ft. 6in. under the footway and about 4ft. to 5ft. under the roadway. The engineer advises that permission to borrow a further £60,000 be obtained to meet the cost of the mains extensions that may be necessary from time to time.

**Devonport.**—The accounts of the Council electricity undertaking for the year ended March 31 last show that the income for traction and lighting for the past year was £15,223, compared with £12 412 for the previous year, or an increase of £2,811. The gross profits were £8,684, against £6,409 in the previous year, an increase of £2,275. The committee have decided to dispose of the gross profit as follows: depreciation account, £3,949; net deficit at March 31, 1904, £1,119; interest on loans, £3,295; balance carried to reserve fund, £320. The gross cost of electricity for the year is ·859d. per unit generated, against ·978d. in the previous year. The decrease is partly due to increased demand. The capital expenditure at the end of the year was equal to £58. 19s. 1d. per 1,000 Board of Trade units generated, compared with £67. 17s. in the previous year, and £79. 5s. 4d. in 1903. The number of units actually generated during the three years was as follows: 1905, 1,857,740; 1904, 1,504,085; 1903, 1,181,559. Mr. J. W. Spark (electrical engineer) in his report says: "The number of private consumers supplied up to the end of the year is 221, an increase of 79 for the year, while the private connections for lighting, power, and heating expressed in the equivalent of 8-c.p. lamps have increased from 15,151 to 21,799. The present extensions to the generating plant are nearing completion, and the supply mains have been extended so as to give an additional supply frontage of one mile." Mr. Spark continues as follows: "The public lighting by electricity in the borough has not been extended this year, so that the unremunerative capital of £970 is still a burden on the undertaking's finances, 1,857,740 units have been generated during the 12 months, and the total cost of production, including all materials, labour, management, insurances, and incidental charges, has been ·859d., making a decrease on last year's result of ·119d. per unit, and the total cost per unit sold has been ·972d., making an economy of ·118d. per unit. The units sold for all purposes amount to 1,642,246, and the sale has been as follows: traction (both companies) 80·09 per cent.; private consumers (general), 15·37 per cent.; private consumers (power), 2·62 per cent.; public lighting, 1·92 per cent. The average price obtained per unit sold has increased from 2·193d. to 2,217d., despite the general reduction in charges to private consumers, made at the commencement of the year, and is accounted for by the larger consumption by private consumers, which this year amounts to 17·99 per cent., against a percentage of 12·7 last year of the total units sold. Your engineer does not recommend any alteration in the charges for electricity at present."

## PROVISIONAL PATENTS, 1905.

MAY 15.

**10138. An electrical apparatus for automatically controlling the speed of motorcars and like vehicles.** George Henry Charles Lumsden, 100, Wellington-street, Glasgow.

**10146. Improvements in electrical resistances.** Emile Rousseau, 23, Leonard-street, City-road, London.

**10168. Automatic device for the ignition of gas by electric currents.** Rudolf Keller, 65, Chancery-lane, London. (Complete specification.)

**10187. Improvements in electric couplings.** John Ebenezer Bousfield, 4, South-street, Finsbury, London. (Firm of Julius Pintsch, Germany.) (Complete specification.)

**10197. Improvements in zinc rods for galvanic batteries of the Leclanché type.** Siemens Bros. and Co., Limited, and George William Perry, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**10202. Improvements in or relating to methods of measuring, switching, signalling, and regulating electric current.** Martin Kallman, 111, Hatton-garden, London. (Complete specification.)

**10210. Improvements in direct-current dynamos and electromotors.** Wilhelm Georg Schmidt, 18, Buckingham-street, Strand, London.

**10211. Improvements in safety devices for use with bare suspended electric conductors.** Arthur Green, 47, Lincoln's-inn-fields, London.

**10214. Improvements in electric current rectifiers.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

**10215. Improvements in vapour electric apparatus.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**10217. Improvements in ropes and means for signalling or transmitting electricity through same.** James Joseph Condon and William Jules Reside, 1, Queen Victoria-street, London.

MAY 16.

**10221. Improvements relating to electric grinders for dynamos and the like.** William Gordon Potter, 13, Mostyn-road, Brixton, London.

**10237. Improvements in connections of metallic and other conduits and tubes.** Albert Edward Hills, Plume-street, Aston, Birmingham.

**10258. Improvements in service, junction, and the like boxes for underground electrical conductors.** Archibald Bruce, 34, Castle-street, Liverpool.

**10265. Improvements in or relating to electrical switches.** Francis Arthur Griffin, 18, Hertford-street, Coventry.

**10288. Improvements in or connected with holders for incandescent electric lamps.** Leo Sunderland and Gilbert Cecil Pillinger, Norfolk House, Norfolk-street, London.

**10291. Improvements in apparatus connected with the multiplication of electric force applicable to machinery of all kinds requiring power.** Thomas James Howell and Edwin Joseph Richardson, 41, Brook-street, Grosvenor-square, London.

**10296. An improvement in electrical fuse boxes.** W. T. Henley's Telegraph Works Company, Limited, and William Henry Nichols, 53, Chancery-lane, London.

**10298. Improvements in electric switches or relays.** Angel Vera and Luis Gonzaga Vera, 7, Southampton-buildings, Chancery-lane London. (Date applied for under Patents Act, 1901, May 17, 1904, being date of application in United States.) (Complete specification.)

**10299. Improvements in and relating to dynamo-electric machines.** La Société Boucherot et Cie., 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 17, 1904, being date of application in France.) (Complete specification.

**10304. Improvements in single-phase alternating-current motors.** Allmänna Svenska Elektriska Aktiebolaget, 322, High Holborn, London. (Date applied for under Patents Act, 1901, Sept. 15, 1904, being date of application in Sweden.) (Complete specification.)

**10315. Improvements in resistances for electric circuits.** Henderson Gibson, jun., and William Bickerton, 18, Buckingham-street, Strand, London.

**10320. Improvements in alternating electric current generators.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**10321. Improvements in electric circuit breakers.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

MAY 17.

**10341. An iron standard for fixing guard boards on electric railways.** George Thomas Trinder and Thomas Duncan Cramb, 26, Palmerston-road, Kilburn, London.

**10400. Improvements relating to the application of fire-alarm apparatus in connection with central battery telephone systems.** Isidore Bernard Birnbaum and Francis George Bell, 322, High Holborn, London.

MAY 18.

**10433. Improvements in and relating to electrical governors for the control of gas-engines used for the generation of electricity.** Hubert Elwell Smith, 95, Buchanan-street, Glasgow.

**10446. Improvements in or connected with the trolley poles of electric tramcars.** Joseph Standring Dronsfield and Charles John Josiah Huntley, 5, John Dalton-street, Manchester.

**10480. Night-sights with electric incandescent lamps for artillery sighting or for any instrument in which night-sighting may be required.** Giacomo Augusto Bertalot, 22, Southampton-buildings, Chancery-lane, London. (Teofilo Bonino, Italy.)

MAY 19.

**10495. Improvements in the methods of charging and discharging accumulators by automatic control.** George Soobel Ellis and Alfred Mills Taylor, 12, Ashfield-road, King's Heath, Worcestershire.

**10509. Improvements in coin-freed electricity meters.** John Meany Tourtel, 146A, Queen Victoria-street, London.

**10553. Improvements in electric arc lamps.** William Stone Weedon, 83, Cannon-street, London. (Date applied for under Patents Act, 1901, May 20, 1904, being date of application in United States.) (Complete specification.)

**10554. Improvements in and relating to electric motor-driven pumps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**10555. Improvements in alternating electric current generators.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

MAY 20.

**10564. Improved system of and apparatus for electric signalling.** William Johnson, Arthur Horton, and William James Berry, Bank-buildings, George-street, Sheffield.

**10573. Improvements in electrical leakage indicators.** Kenelem Edgcumbe, Collindale Works, Hendon, London.

**10581. Automatic switch for electric railways.** Victor Jokscb, Josef Petrik, and Richard Butta, 65, Chancery-lane, London. (Complete specification.)

Digitized by Google

**10584. Improvements in or in connection with electric bells.** Thomas Blackburn Lowrance, Joseph Robert Ryder, and William James Lowrance, 3, Brown-street, Market street, Manchester.

**10599. Electromagnetic ignition device for explosion engines.** Willy Roos, 65, Chancery-lane, London. (Complete specification.)

**10601. Improvements in and connected with wireless telegraphy with earth currents.** Ludwig Zehnder, 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, May 20, 1904, being date of application in Germany.) (Complete specification.)

**10605. Fraud detector for electric meters.** Wallace Watt Fuller, 81, High Holborn, London. (Date applied for under Patents Act, 1901, May 20, 1904, being date of application in United States.) (Complete specification.)

**10609. Improvements relating to electric advertising signs.** Leonard Kingwill Job, 322, High Holborn, London.

**10610. Improvements in switching devices applicable to electric flash advertising signs.** Leonard Kingwill Job, 322, High Holborn, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published June 8.*

1904.

**11233. Electric meters for three-phase alternating electric circuits.** Union Elektricitäts-Ges. (Date applied for under International Convention, May 15, 1903.)

**11264. Electrically-propelled vehicles.** Thayer.

**11364. Electric alternating-current distributing systems.** Merz and Price.

**11443. Electric switches.** British Thomson-Houston Company, Limited. (General Electric Company.)

**11532. Prepayment meters.** British Thomson-Houston Company, Limited. (Allgemeine Elektricitäts-Gesellschaft.)

**11720. Electric switches.** Green and Hallam.

**12245. Electric switches, circuit breakers, and the like.** British Thomson-Houston Company, Limited, and Cubitt.

**13527. Electrical measuring and indicating devices.** Hughes.

**14741. Protecting electric apparatus against reversal of energy flow.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15332. Sliding apparatus for raising or lowering chandeliers, electroliers, gas pendants, and the like.** Lea and Perrins.

**15517. Dynamo-electric machines for hand working.** Lommatzsch and Siegert.

**15633. Hoisting apparatus.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15764. Electricity meters.** Mordey and Fricker.

**15779. Boxes, covers, or containing cases for electric switches, fuses, and the like.** Marsh and Mudie.

**16242. Gas electric lamps and arc lamps** Beck. (Date applied for under International Convention, June 24, 1903.)

**16393. Automatic electric cut-out switch.** Javaux.

**16418. Electrically-driven winding engines.** Raky.

**16603. Electric arc lamps.** Jones and Jandus Arc Lamp and Electric Company, Limited.

**17011. Voltaic cell or element.** Delafon.

**23084. Switches for reversing the current in electric motors.** Whittingham. (Date applied for under International Convention, Oct. 29, 1903.)

1905.

**513. Alternating-current commutator motors.** Zani.

**881. Apparatus for automatically indicating loss or passage of electric current.** Wieland.

**1920. Securing laminated cores of dynamo-electric machines.** Burke.

**1921. Dynamo-electric machines** Burke.

**3401. Resistances for electric current.** Hopfelt.

**7101. Apparatus for absorbing gases by a liquid under the action of the silent electric discharge.** De Hemptinne.

## NOTES.

**The Electrical Contractors' Association.**—The annual dinner of this association will be held in the King's Hall of the Holborn Restaurant on Tuesday, the 27th inst., at 6.30.

**Wireless Telegraphy.**—It is reported that the Postmaster-General, the Minister of Defence, and Vice-Admiral Sir Arthur Fanshawe, commander-in-chief on the Australia Station, are considering an extensive scheme for installing a wireless telegraphy system to connect Australia, New Zealand, and the outlying islands.

**Canada's Telephone System.**—One of the chief witnesses before the Canadian Telephone Committee last week was Mr. H. Laws Webb, who declared that the Government ownership of telephones was proving a failure, while the Glasgow municipal system was partly obsolete. Mr. Webb's statements are reported to have made a considerable impression upon the committee.

**The Students' Section.**—The students held twelve meetings during the past session, and visits were paid to a like number of works. A party of students paid a visit to Leeds last month, when they inspected a number of important works. The first annual dinner, which was held at the Holborn Restaurant, proved a decided success. The committee desire to express their satisfaction at the results of the past session's work, and trust that the high standard will be maintained.

**Rugby Engineering Society.**—This society paid a visit to the generating station of the London Underground Electric Railways Company at Lots-road, Chelsea, on Saturday, the 20th ult. Seventy-five of the members availed themselves of the opportunity granted through the courtesy of Mr. J. R. Chapman, general manager, of inspecting this extensive station. The whole of the station was thrown open for inspection, and the party were allowed access to practically all parts of the station.

**The Institution.**—At the Society of Arts last week a large company of the Institution assembled to hear Messrs. W. Duddell's and J. E. Taylor's paper on "Wireless Telegraphy Measurements." Mr. Duddell's delivery of the paper was punctuated by frequent and enthusiastic applause. In the brief discussion which followed, Mr. Gavey paid a tribute to the value of the authors' researches into the measurements of wireless currents, and this was echoed by Captain Jackson, R.N., who has had extensive experience of wireless telegraphy in the Navy. Dr. Sumpner was also congratulatory.

**The Pacific Cable Conference.**—From reports in the daily Press it appears likely that this conference, which has several times been postponed owing to the difficulty of assembling all the delegates at the same time, will really arrive at fruition in the course of the present month. The first of the sittings, which are to be held at the Colonial Office, is announced for the 21st inst. The Australian Commonwealth will be represented by Lord Jersey, New Zealand by Sir Sandford Fleming, Canada by Sir William Mulock (Postmaster-General of the Dominion), who is expected to sail for England to-morrow, and Great Britain by the Secretary of State for the Colonies.

**Patents.**—Attention is called by Mr. C. Crossley, of 9, Zenobia-mansions, W., to a measure now before Parliament which our correspondent considers will prevent inventors from availing themselves of expert engineering or similar assistance in preparing their applications, thus forcing them to obtain this assistance through patent agents at additional expense. Mr. Crossley refers to the attempt to pass a similar Bill by the Chartered Institute of Patent Agents some few years ago. This Bill was withdrawn after it had been considered by a committee, who stated in decisive terms their opinion that an inventor should not be compelled to employ any particular class of agent or any agent at all, and that it would be most undesirable to create a monopoly in such matters. The matter is one of great importance, but our correspondent appears to be under some little misapprehension, as the general tenour of the Bill is designed to facilitate rather than to obstruct applications for patents.

**The Metric System in Australia.**—It is reported from Australia that one of the Bills to be introduced in the coming session of the Commonwealth Parliament will have reference to an important phase of economics. It relates, in fact, to the metric system. The Bill is expected to follow the lines of that recently passed by the New Zealand Parliament, under which a proclamation may at any time be issued, giving effect to the metric system throughout the country from the beginning of next year. The measure has for some time been under the consideration of the Minister of Commerce. The powers to be contained in the measure have not yet exactly been defined. The system is for a time to be permissive, but power is reserved to give it compulsory effect after a day fixed by the Governor-General in Council. At one time in the Federal Parliament there was a suggestion that the metric system of weights and measures and decimal system of coinage should be introduced concurrently. This has, however, not been found to be practicable.

**The London Power Bills.**—As mentioned in our last issue, clauses were inserted in both the Administrative County of London and District Power Bill and in the Bill extending the powers of the Metropolitan Electric Supply Company in order to protect the Metropolitan Water Board. The clause as approved provides that the companies in question shall compensate the Water Board for any injury or damage to water-pipes or other metallic pipe structures or substances of the Board which shall prove to have been caused by fusion or electrolytic action by currents generated by the companies. It will be seen that under this clause damage has to be proved, and as the companies in question are most likely to employ three-phase currents, electrolytic action is not so liable to result from leakage. It still leaves open, however, the difficult question of proving how much corrosion on a given pipe may be due to the ordinary electrolytic action which takes place in all buried pipes and how much is due to leakage currents.

**Canadian Electrical Association.**—This institution will hold its annual convention in Montreal on the 21st, 22nd, and 23rd inst., the arrangements for which are rapidly approaching completion. The following is a preliminary list of papers: "Transformers," by Mr. R. T MacKeen, Canadian General Electric Company, Toronto; "Operation of Transformers at Varying Frequencies and Voltages," by Mr. Sammett, Montreal Light, Heat, and Power Company; "Induction Motors," by Mr. Burson, Allis Chalmers-Bullock Company, Montreal; "Economy of Isolated Plants," by Mr. T. L. Aitken, consulting electrical engineer, Toronto; "Carrying Capacity of Enclosed Conductors," by Prof. R. B. Owens, McGill University. The question-box, under the able direction of Mr. A. A. Dion, of Ottawa, is expected to prove a feature of great value. A trip to the Shawinigan Falls is also under consideration, and the laboratories of McGill University will be open to inspection by the delegates during the convention. The social side will also come in for due attention.

**Electricity in Cotton Mills.**—At a recent meeting of the New England Cotton Manufacturers' Association Mr. Sydney B. Paine contributed a paper giving the result of a test of a cotton mill equipped with electric power. The author had compiled a detailed record of 128 different textile companies which together use some 90,000 h.p. of electrical energy, and it is estimated on a conservative basis that some 175 textile mills in the States are using electrically about 140,000 h.p. The late United States census report shows that 22 mills are driven entirely by current generated by outside companies, while a similar number purchase 5,586 h.p. to supplement the power generated upon the premises. The paper gave charts from a recording wattmeter taken from a 200-h.p. motor operating 52 frames aggregating 11,648 spindles. The spindle speed was about 900 revolutions per minute. Eleven records were obtained, with variations in the conditions, including the temperature and humidity. The average load was in the neighbourhood of 150 h.p., the smallest being 148·5 h.p. and the largest 157 h.p. In the latter case the maximum output of the motor was 190 h.p., the minimum output of the motor 144 h.p., the ratio of average to maximum load 82·7 per cent., and the ratio to the motor rating 78·5 per cent. The average load throughout the test was about 10 h.p. per frame.

**Pneumatic Tube Dispatch.** — The favourable evidence given last week by a number of eminent engineers on behalf of this measure was supplemented by the views of other distinguished witnesses. Mr. C. A. Brereton stated that he had visited America in order to satisfy himself as to its working, and was struck by its extreme simplicity. There would be no difficulty in installing the system in London. In cross-examination, the witness admitted that in times of emergency and pressure of business it might be necessary to send parcels through the tubes by a circuitous route owing to the main tubes being fully occupied. Prof. Carus Wilson considered that as the telephone came to be more generally used in London it would entirely alter the aspect of parcel delivery. In his opinion the more extended use of the telephone would inevitably lead to a demand for quicker delivery of goods. The electrification of railways would lead to the abandonment of parcel delivery by the railways. With the increased knowledge of pneumatics that had been acquired in recent years the essential features of success in a pneumatic delivery system were accurately known, and the Batcheller system possessed those features. Despite this general consensus of opinion, the committee came to the conclusion that the promoters had not proved the preamble of the Bill, and rejected same without calling upon the opposition to state their case.

**The Electrical Engineers R.E.V.**—An exhibition was given by the corps at headquarters last Saturday, when the engines, dynamos, and searchlights were seen in operation under the supervision of Captain Edgcumbe. There are three dynamos of 80 volts, 150 amperes, exact duplicates of those installed at all British forts for searchlight purposes. Two are driven by oil-engines. The third is operated by a steam-engine, which, though this form of prime mover is practically obsolete for such work, is retained for instructional purposes. Great interest and attention was shown by the members of the corps in the performance of their functions. A portable oil-engine and dynamo used in the South African campaign was also on show. After witnessing the searchlight in the emplacement, our representative was conducted to an upper chamber, divided into two compartments, which are being prepared on the plan of a regular fort for searchlight practice, as the view afforded by the lower floor is decidedly circumscribed by the surrounding walls. Another feature on show was the trophy awarded by Prof. B. Hopkinson, son of the founder of the corps, for efficiency in technical work. For this test the engines were taken to pieces and put out of order, and the competitors had to see who could rectify matters in the quickest time, D company proving successful. The corps, it may be remarked, is participating in the Military Tournament at the Agricultural Hall. The various attractions having been inspected by the goodly company assembled, an adjournment was made for tea, after which harmony reigned.

**The Telephone Transfer.**—The Select Committee appointed by the House of Commons commenced its sittings on Tuesday, the first witness being Sir Robert Hunter, solicitor to the Post Office. Sir Robert stated that if an agreement between the Post Office and the company were not consummated at the end of 1911 the company would be unable to work its system, and unless something were done telephone business would come to a standstill. The witness stated that the objection to the Postmaster-General constructing an alternative system in lieu of acquiring the company's, was that it would take at least six or seven years to put down a plant equal to that of the company. Sir Robert Hunter explained at length the details of the terms of purchase by the Postmaster-General of the company's system. The price to be paid was to be what it would cost the Postmaster-General to put up the same plant, subject to reduction for depreciation and subject to the right of objection to certain things which were not suitable for his purpose. Sir Robert stated that the advantages of the agreement were that it provided for the continuance of the company in the meantime; it gave the Postmaster-General a plant at the price which he would have to pay if he constructed it himself (subject to depreciation); and it gave guarantees for the maintenance of the service with the National Telephone Company in the intervening time. In reply to a question, the witness agreed that the effect of the competition in telephones in London had been that the increase in the company's system was equal to the total business of the Post Office system.

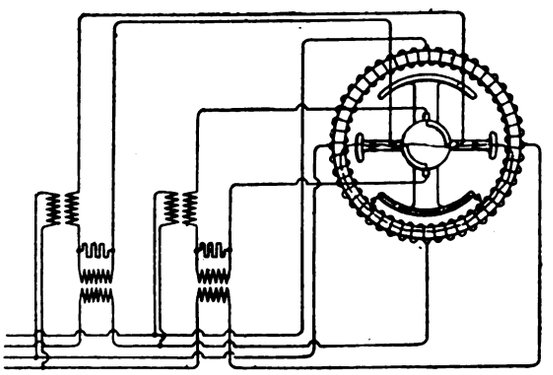
**The American Engineering Club.**—The architects of the United Engineering Building for the various American societies have filed plans with the superintendent of buildings giving some of the details of the 15-storey structure, to cost £200,000, presented by Mr. Andrew Carnegie. It is to be erected in West Thirty-ninth-street, and immediately adjoining it in the rear will be the 13-storey clubhouse of the Engineers' Club, which is also part of Mr. Carnegie's gift to American engineers. The Thirty-ninth-street building will be a fireproof edifice, 212ft. high, with a frontage of 115ft. and a depth of 88·9ft. It is to be in the style of the French Renaissance, and light will be admitted through five rows of tall decorated windows, panelled in bronze. The entrance will be adorned with fine doors of decorated bronze, and will be flanked by columns supporting bronze candelabra. Three ornamental balconied doorways, with bronze doors, built just above the entrance cornice, will be flanked by statuary, and the roof cornice and its frieze will be supported by a series of engaged columns and pilasters rising from the thirteenth storey. The façade is to be of granite and limestone trimmed with terra-cotta. The main floor of the building is to have a main central entrance hall, and opening off it at the corners will be the general administration office, the smoking-room, reception-room, and a writing-room. The third and fourth storeys will contain an auditorium, with a balcony having spacious promenades on the north and south. The fifth floor will be fitted with smaller assembly halls, and the sixth floor will contain a series of lecture-

Digitized by Google

rooms. The seventh to eleventh floors will be devoted to offices for the respective societies. The library will occupy the thirteenth and fourteenth floors. It will be remembered that the American Institution of Civil Engineers decided not to identify themselves with the scheme, but with this exception the movement has received the co-operation of all the important organisations.

**The Embankment Scheme.**—The London County Council have made more progress with their scheme for carrying the trams over Blackfriars Bridge than they were able to achieve at their former attempts, though the Bill has other stages to pass through yet before it becomes converted into an Act. Moreover, the House of Commons committee, in finding the preamble proven, have made certain stipulations, one of which at least is of a decidedly onerous character. The committee came to the conclusion that the widening of Blackfriars Bridge was "imperative." Sir Ralph Littler reminded the chairman that the Council have no powers for this purpose, but the latter replied that he well appreciated the position, and that the committee would take care to see they did not do anything which was *ultra vires*. Whatever be the character of the widening it is pretty certain to entail a pretty substantial outlay, and it is even possible that it may result in again postponing the scheme. A protective clause will be inserted in favour of the Metropolitan Railway Company, who contended that the continuous traffic would endanger the brickwork of their tunnel. The committee do not appear to have attached much importance to the contention that the embankment is not sufficiently well constructed for tramway traffic, and the usual bogey put forward by the æsthetes failed to move them. If the extension does materialise, it will at least afford an opportunity of judging whether the various objections were ill-founded. On Wednesday the committee again met to settle the form of the clause in regard to the widening of Blackfriars Bridge. Mr. Erskine Pollock, K.C., on behalf of the Council, submitted a clause providing for the postponement of the tramway line for six months, during which time the Corporation and the Council should be at liberty to negotiate terms for the widening. If the Corporation failed to give notice of their requirement, or to contribute substantially towards the cost, the clause provided that the Council might construct the tramway over the existing bridge. After considering the matter, the committee intimated that the widening of the bridge must be a condition precedent to the approval of the Bill, and the matter would stand adjourned for a month to give the Council and the Corporation an opportunity of arranging terms.

**Self-Exciting Alternating-Current Generator.**—Two patents have been issued in the United States to Mr. E. F. W. Alexanderson relating to alternating-current generators of the type in which the current for field excitation is obtained from the armature and rectified by means of a commutator. A description of same appears in the *Electrical World*. On a two-part commutator, the segments of which are connected permanently to the terminals of the field coils, pairs of brushes are placed equal in number to the number of phases of the machine. These brushes are subjected to E.M.F.'s derived from the secondaries of potential transformers. To render the exciting circuit practically non-inductive and to compensate for varying power factors and values of the loads on the machine there are placed in series with the potential transformers non-inductive resistances, across which are connected the secondaries of series transformers. The series transformer serves to impress upon the terminals of the resistance connected in the exciting circuit a potential varying in magnitude and phase with the current in the main circuit. A disadvantage found when this scheme is used in its simple form resides in the fact that the proper neutral E.M.F. points on the commutator, at which the brushes should be placed for sparkless operation, vary with the time phase of the exciting voltage, which changes with both the value and power factor of the load. The inventor has observed that the reaction of the armature current on the field magnetism tends to balance this variation, since it shifts the time phase of the generated E.M.F., and consequently of the exciting E.M.F. derived from the potential transformers, relatively to the mechanical position of the poles and of the commutator segments. In order to make the counterbalancing more effective, the inventor provides small auxiliary poles placed between the usual field poles so as to offer a low reluctance path for the armature flux at points between the poles produced by the



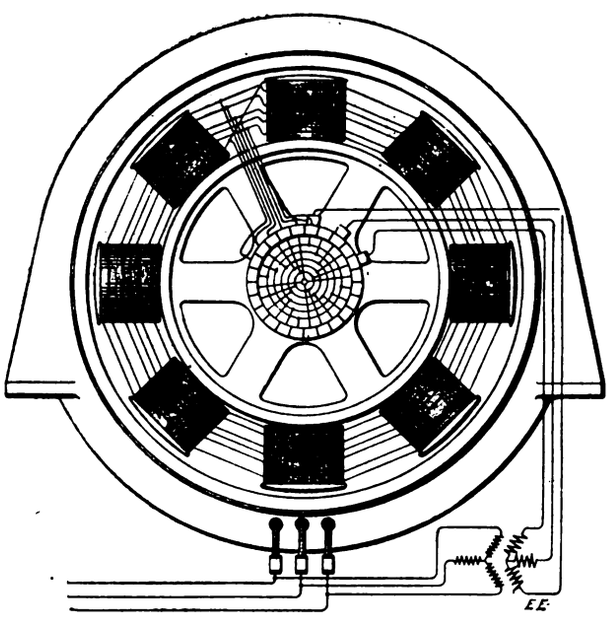
field winding, as indicated in the accompanying illustration.

**The Value of Advertising.** — A lecture upon publicity as an aid to industry was delivered at the annual dinner of the Manufacturers' Advertising Club, Cleveland, U.S.A., by Mr. Arthur Warren (manager of the Allis-Chalmers Company's advertising department), who recently created a considerable stir across the Atlantic by his candid remarks upon technical and commercial journalism, to which we referred in our issue of March 24. The Cleveland Manufacturers' Advertising Club, which was established a year and a half ago, is the only organisation of its kind in the States, but it appears likely that its lead will be followed before long. Mr. Warren remarked that a department of publicity is a trade scout. It goes out in advance, a long way in advance, of the army of salesmen, and stirs up the possibilities of business. Publicity brings business. Manufacturers who do not buy publicity as liberally as they buy other selling facilities will some day have to take their places at the rear of the procession. The manufacturer who does not provide a publicity department of his own, small or large, and push it and develop it as he does any other branch of his business, is neglecting a great and profitable opportunity. "Everybody, once in a while, is curious," he proceeded, "regarding 'follow-up systems.' I am trying to invent one. It is not perfect, but it has its good points. I have never known a perfect system, whether of 'following-up' or of anything else. No system, whether it be of business, of government, or philosophy, is better than the men who work it. Most 'follow-up systems' are too complicated: they entail too much clerical labour. A 'follow-up system' that produces results without complexity is a good trade-getter. But it must be adapted to the special needs of a business. The reason so many systems break down is because they are imitations of what other people do. No system is effective without brains behind it. You must not only 'follow up' your public, but you must follow up your system.'" Further advice of the lecturer's was:

Digitized by Google

"Don't take a narrow view of publicity. Don't swamp productive work with clerical work. A general in command cannot fire the guns, cannot count the ammunition used in battle, and cannot tabulate the list of slain and of wounded—on the other side. Advertising, whether direct or indirect, must be done generously if it is to bring results. The chief thing is to let the world know who you are, where you are, and what you are doing; and you cannot do this on a large scale by stopping to take a census every time you fire a volley." Mr. Warren concluded: "I am a believer in direct advertising as well as in indirect; in the mailing list as well as in the best trade journals. Each does what the other cannot do. Each is essential."

**Alternating-Current Generator with Polyphase Excitation.** — An interesting form of self-exciting generator is comprised in a patent granted in the United States to Mr. M. C. A. Latour, of which a description appears in the *Electrical World*. The winding of each individual field coil is in six sections. The corresponding sections of all of the field coils are connected in series with each other, so as to form six groups. These six groups are then placed in series in a closed circuit, the end of group No. 6 being connected to the beginning of group No. 1, as will be seen in the accompanying diagram.



The six junction points between the groups are connected to a rectifying commutator containing six segments per pair of poles, interconnected in sets corresponding to the number of pairs of poles, as will also be seen in the accompanying illustration. Polyphase E.M.F. is impressed upon the commutator by means of suitable transformers. The number of turns in each group of coils is so selected that the resultant magnetomotive force of the currents in all of the groups due to the alternating E.M.F.'s impressed upon the several groups will remain at all times unidirectional and of a practically constant value. The inventor states that the successive groups should contain the number of turns represented by the following expressions: number of turns in first group $= k \sin a$; number of turns in second group $= k \sin \left(a + \frac{2\pi}{n}\right)$; number of turns in third group $= k \sin \left(a + \frac{4\pi}{n}\right)$, etc., $k$ being a constant, $a$ being any chosen angle, and $n$ being the number of groups.

**Electric Lighting in New York.**—During the recent investigation into the electric lighting service of New York some interesting features were brought to light at the instance of the New York Edison Company. The service from the series arc lighting systems had become less and less satisfactory, and during 1902-3-4 the city street lamps were gradually changed over to the low-tension, direct-current, enclosed arc system. In 1903 and 1904 the series arc lighting systems were operated at an actual loss, the cost of a city arc lamp of 2,000 c.p. per year averaging £33, as against the price to the city of £30. In 1903, owing partly to the cost of effecting these changes, the cost of the low-tension enclosed arc lamps was £28, allowing only a small margin—less than 5 per cent.—of profit. In 1904 the conditions improved somewhat, but the margin above actual cost did not allow more than a reasonable profit considering the character of the business. In the meantime most of the old, unsightly wooden lamp-posts, prescribed by the old Board of Electrical Control for high-tension lamps, had been removed, and these were substituted by ornamental iron posts. In the case of the lamps in two large streets, the average cost of the service for the three years 1902-3-4 was £34 per lamp per year. The price charged the city for this service (£37) seems reasonable enough, allowing only a fair margin of profit. The price of arc lamps in the borough of the Bronx, of which there are over 1,100, was voluntarily reduced in 1902 from 1s. 10½d. to 1s. 8d. per lamp per night, and a number of lamps in particular localities in the borough of Manhattan, for which the city had previously paid 2s. 1d. and 1s. 10½d. per lamp per night were reduced at the same time to the uniform rate of 1s. 8d. per night. The history of the lighting rates in New York City for private consumers began with a maximum charge of 11d. a kilowatt-hour, without discounts other than those obtained through special contracts. After several years of this method of charge, the price was reduced to 10d. a kilowatt-hour, with certain graduated discounts. For some time, however, the companies failed to offer adequate inducements to the long-hour consumer, but eventually they adopted a maximum charge of 10d. a kilowatt-hour during the first hour only of average use, thereafter making a reduction, not because of the quantity used, but because of better average use, of 25 per cent. for the second hour of average use, 50 per cent. for the third and fourth hours, 75 per cent. for all in excess of four hours. This was the retail rate upon the establishment of the New York Edison Company in 1901. Recognising the benefits, existing and prospective, that had accrued to the company from consolidation, this price was voluntarily reduced to a maximum of 7½d. during the first hour as well as the second hour of average use, representing in its aggregate a reduction of some £200,000 annually upon the present revenues of the company.

**The Mercury Arc.**—At the recent meeting of the American Electrochemical Society Dr. E. Weintraub presented a paper detailing the results of his investigations into the nature of the conductivity of the metallic vapours, as the result of which the author has devised a new method of starting an arc discharge in mercury vapour. According to the author's conception, an arc discharge in metallic vapours is a discharge deriving its carriers at least in the immediate neighbourhood of the cathode from the material of that cathode. The application of a moderate E.M.F. is of itself insufficient to start the process by which these carriers are formed out of the material of the cathode. The new fact discovered was that this formation of carriers (the "ionisation" process) is started and the arc discharge made possible if a spark or a small arc is produced at the surface of the cathode. The operation is graphically described thus: The tube is represented in Fig. 1. K is a cup filled with mercury. A and B are electrodes of graphite,

Digitized by Google

iron, or mercury. In the figure they are shown as mercury cups. The tube is exhausted by a Sprengel pump to the highest possible vacuum, and by some means, such as heating from outside, or by the arc itself, the gases are driven off from the walls of the tube and the anode material. Two different sources of direct current are used, one applied to K and B, the other to K and A, in such a way that K is the negative pole of both. If, now, the little arc, B K, is started by bringing the electrodes into contact, and separating them, the other arc, K A, starts instantaneously. If the connections are changed in such a way that K is the common positive pole of the two sources, the arc B K does not cause the starting of the arc A K. The fundamental importance of the cathode in the process of starting an arc is illustrated by this experiment in a simple and striking way. In the tube shown in Fig. 1 the use of two different sources can be dispensed with, and the same source used with different resistances in the two branches. In Fig. 2, B is the cathode, D and A are both connected to the positive pole; $r$ is a large resistance; $r$ is a small resistance used for the purpose of regulating the current in the main arc, B D.

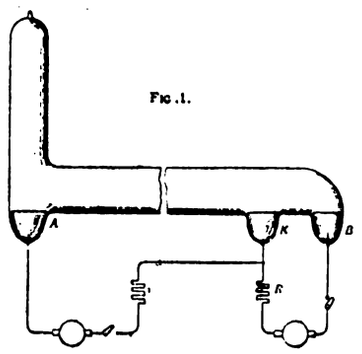


FIG. 1.

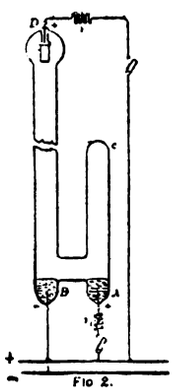

FIG. 2.

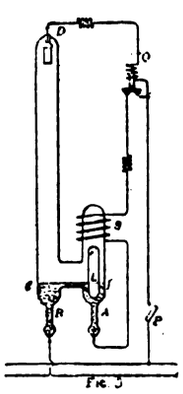

FIG. 3.

By slightly shaking the tube, the arc B A starts, whereupon the arc B D can then be opened and the auxiliary arc disconnected. For the practical use of this starting method, the operations of separating the electrodes B and A and discontinuing the auxiliary arc the moment the main arc is started, must be performed automatically by the cutrent itself. One of the arrangements that have been devised is represented in Fig. 3. K L is an iron plunger, S a solenoid, and O a magnetic cut-out. The solenoid, S, in pulling up the plunger, K L, produces the auxiliary arc. The current in the main arc flows through the magnetic cut-out, and automatically opens the circuit of the auxiliary arc. It will be seen that this method of starting an arc by contact through excitation of the cathode is similar to the old method, the only difference being that instead of having one arc instantaneously formed by another, there is a continuous growth, a short arc producing a longer one. Of the devices used by the author special mention is made of two. In both of them the tube contains three electrodes, one of mercury, the others of graphite, iron, or mercury. The one electrode of mercury serves as the cathode, the two others serve as anodes of the rectified arcs. In the first arrangement, represented in Fig. 4, a transformer is used, the ends of the secondary of which are connected to the two graphite anodes. A wire taken out from the middle of the secondary is connected to the cathode. One half-wave takes then in the arc the direction A K, the other the direction B K, and both are superposed in the same direction in the neutral wire of the transformer. The current derived is pulsating, and if the rectified voltage or current is low, usually a small direct-current arc, springing from the same cathode, is necessary to keep the cathode alive during the zero point of the current. If a constant-current transformer is used, this direct-current arc can be dispensed with. In the second method the alternating voltage is directly applied to the two graphite electrodes, and two reactance coils are connected in the way shown in Fig. 5. The reactances store up energy, while the current flowing in them increases and discharges through the arc in such a direction as to keep the cathode, K, alive. In this case, as in that of the one previously described, a great number of modifications and combinations have been devised for both monophase and polyphase currents. Voltages up to 15,000 have been thus rectified, giving unidirectional E.M.F. as high as 6,000 to 7,000 volts. Starting from the hypothesis developed by a number of modern scientists, according to which the conduction in

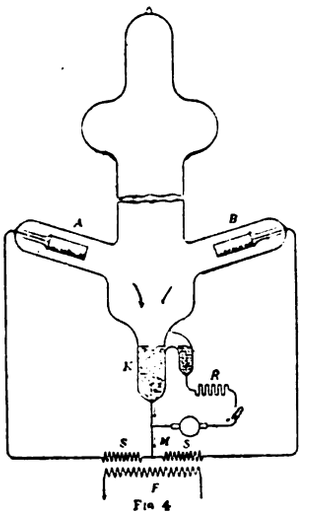

FIG. 4.

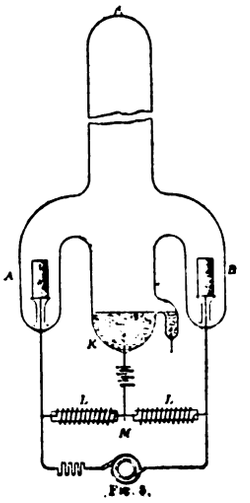

FIG. 5.

metals is due mostly to the negative electrons, and from the postulate that the mechanism of conduction in different states of matter must have the same general characteristics, the author assumes that the mechanism of the conduction in the arc is similar to that in metals, and that an arc is, electrically considered, in the main a flow of negative electrons directed from the cathode toward the anode. While in the metal the number of electrons is a given quantity and the conductivity accordingly constant, the number of electrons crossing the surface of the cathode and entering into the arc must be proportional to the current. Accordingly, the conductivity of the arc is proportional to the current. The process of starting an arc serves to initiate the process by which the electrons are driven out from the metal into the space. The starting is probably produced by purely electrical causes. If this process, by means of which the negative electrons are projected out of the metallic mass, is started, it goes on of itself so long as a sufficient amount of energy is applied. The disintegration of the cathode is a mechanical accompaniment of this electrical process. The light emitted by the arc is not due directly to the radiation of the electrons. These negative electrons are probably the same in all arcs, and the light emitted changes according to the molecular material through which these electrons move. We abstract the foregoing from the *Electrical World* of New York,

## ELECTRICALLY-DRIVEN WINDING ENGINES.

Englishmen are proverbially slow to adopt new methods, and in no home industry, perhaps, is this characteristic more marked than that of mining. It has been left to the Continent to do all the pioneering work in regard to improved winding engines, while over here many a machine is still called upon for service whose fabric would be deemed of interest by the antiquarian, and whose rightful place is, therefore, the museum. But the question of economical winding increases in importance with the depth and output of the mines worked, whence it follows that mine-owners who have hitherto been unprogressive will be compelled by necessity to seek improved methods in the future. And they will have Continental experience to guide them. In every case where electrical driving has been adopted, the cost of winding has been considerably reduced. We have it on the authority of Dr. Herzfeld that the amount of steam consumption per horse-power hour on mineral raised is in some cases as low as 24lb. to 26lb. The constant turning moment of an electric motor is more favourable to the life of the ropes than that of a steam-engine, where the torque varies from 0 to a maximum. It prevents dangerous waves in the ropes, while it is well known in mining circles that the variations of torque in a steam-engine cause "dancing," and consequent overstrains. Another great advantage of electrical winding engines, and one of the reasons why the energy required is less than in steam plants, is that steam winding machinery requires a very heavy drum to balance the varying torques. It is only necessary to mention the principal consequences of the heavy weight of the drum—viz., the high initial expenses, the large amount of energy consumed during the acceleration period, and the extraordinary size of the driving engine, which possesses all the disadvantages of machines having a greater capacity than their average load.

One of the first essentials for economical winding is constancy of load at the generating station. For a long time past, therefore, the builders of winding engines have taken care to balance the varying weights of the winding ropes, and several systems have been developed, the oldest of all being the bobbin system, which consists of two guides, between which the rope, generally flat, coils itself. This system, however, has not come into use in this country, on account, it is suggested, of the difficulty of obtaining the flat ropes—not a very adequate reason, it may be thought. An arrangement of conical drums for balancing the weights of the ropes, in which the gradient is so determined that the resulting turning moment due to the weights of the ropes, cages, and trains is zero, is therefore preferred to the former system. But this arrangement is an expensive one, and some mine-owners prefer cylindrical drums and balancing the weight of the rope by a tail-rope. Both of the latter methods are much used in this country. Some 20 odd years ago another system was developed on the Continent, known by the name of the "Koepe wheel," which compares very favourably with those above mentioned. In this system a grooved pulley is fitted on the shaft of a winding engine, and around this the rope, to the ends of which the cages are attached, is passed, the load being lifted by the friction between the rope and the pulley only. The weight of the rope is in every case balanced by a tail-rope attached to the cages, forming an endless system.

In considering what system and what type of motor should be applied for winding plants, it is of importance to know whether an electric supply of one or other kind is already available, or whether a new power-house is to be laid down. If there be an existing supply of polyphase current, the periodicity will, of course, influence the choice. The use of special starting arrangements for the winding motor has also to come into consideration. This becomes the more necessary if the winding plant is to be connected up to public supply mains. One of the systems which has been successfully installed to meet the latter condition consists of a converter set working in combination with the winding motor. It is known, after its original inventor, as the Ilgner converter system, and is a combination of a flywheel and a polyphase or continuous-current motor driving a continuous-current generator, being so arranged as to take an almost steady current from the supply network, although the actual supply of current to the winding motor will vary enormously. There are also other patent forms of control in use for the winding motors where the ordinary resistance control is inadvisable. These include systems with "buffer" batteries, counter-voltage control with balancing flywheels, Leonard control, etc., all of which have for their object the minimising of power losses in starting, stopping, and speed regulating, and the employment of less costly resistance apparatus, through which the main motor current need not pass. In the Leonard arrangement of plant, the generator used for supplying and starting the winding motor, as also the motor itself, are separately excited. The starting and speed of the winding motor, then, depends solely on the changing of the excitation in the continuous-current generator. This variation of the exciting current, which only amounts to a few per cent. of the main current, is effected by ordinary resistance regulation in a small controller operated by the driver, which is so arranged that any desired speed between zero and maximum can be obtained. By altering the direction of the exciting current the motor

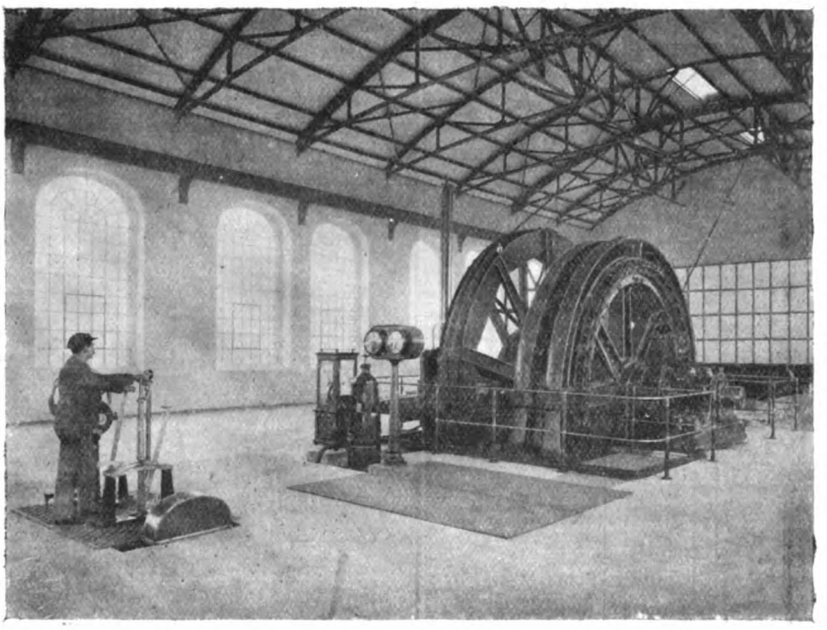

FIG. 1.—Winding Plant at "Preussen II." Pit.

Digitized by Google

can also be reversed. This form of control of the starting and speed regulation of the winding motor is also always used with the Ilgner system.

We will now proceed to describe some typical installations erected by the Allgemeine Elektricitäts-Gesellschaft, Berlin, to whose representative on this side, the Electrical Company, Limited, 121-125, Charing Cross-road, London, W.C., we are indebted for the particulars here given.

### Winding Plant at "Preussen II." Pit.

The accompanying illustration (Fig. 1) is a view of the winding plant at the "Preussen II." pit of the "Harpener Bergbau" Company's coal mines near Dortmund, while the diagram (Fig. 2) explains in detail the working of the plant and gear. This plant deals with an output of 100 tons of coal per hour, mined from a depth of 2,310ft. The installation, suiting the requirements of the case, was designed on the three-phase system with liquid resistance control for the winding motor. The generating plant consists of three three-phase revolving-field machines, each of 550 kw. output, working at 2,100 volts, with a frequency of 25, and at 94 revolutions per minute, the armature

For inspection of the shaft and rope, etc, any desired speed, ranging down to about 20in. per second, can be easily obtained. The winding drum is direct coupled to an A.E.G. three-phase induction motor with slip-rings. The 2,000-volt current is brought to the motor through insulated cables. From the diagram (Fig. 2) it will be seen that the current from the supply station goes through high-tension fuses to an emergency switch. Beyond the latter is arranged the reversing switch for altering the direction of rotation of the winding motor. This switch is actuated directly from the controlling lever, and the lever is set up for the driver in precisely the same way as in the case of a steam winding engine. In the mid position of the lever the current is switched off, and the motor electrically disconnected. By movement of the lever to left or right the current is sent through the stator of the motor for one or the other direction of rotation. The actual starting of the motor, as also its speed regulation, is controlled through the rotor windings and by means of a patented arrangement of liquid starting and regulating resistances.

Each of the three phases of the rotor is led to the resistance plates, which are insulated and suspended in the

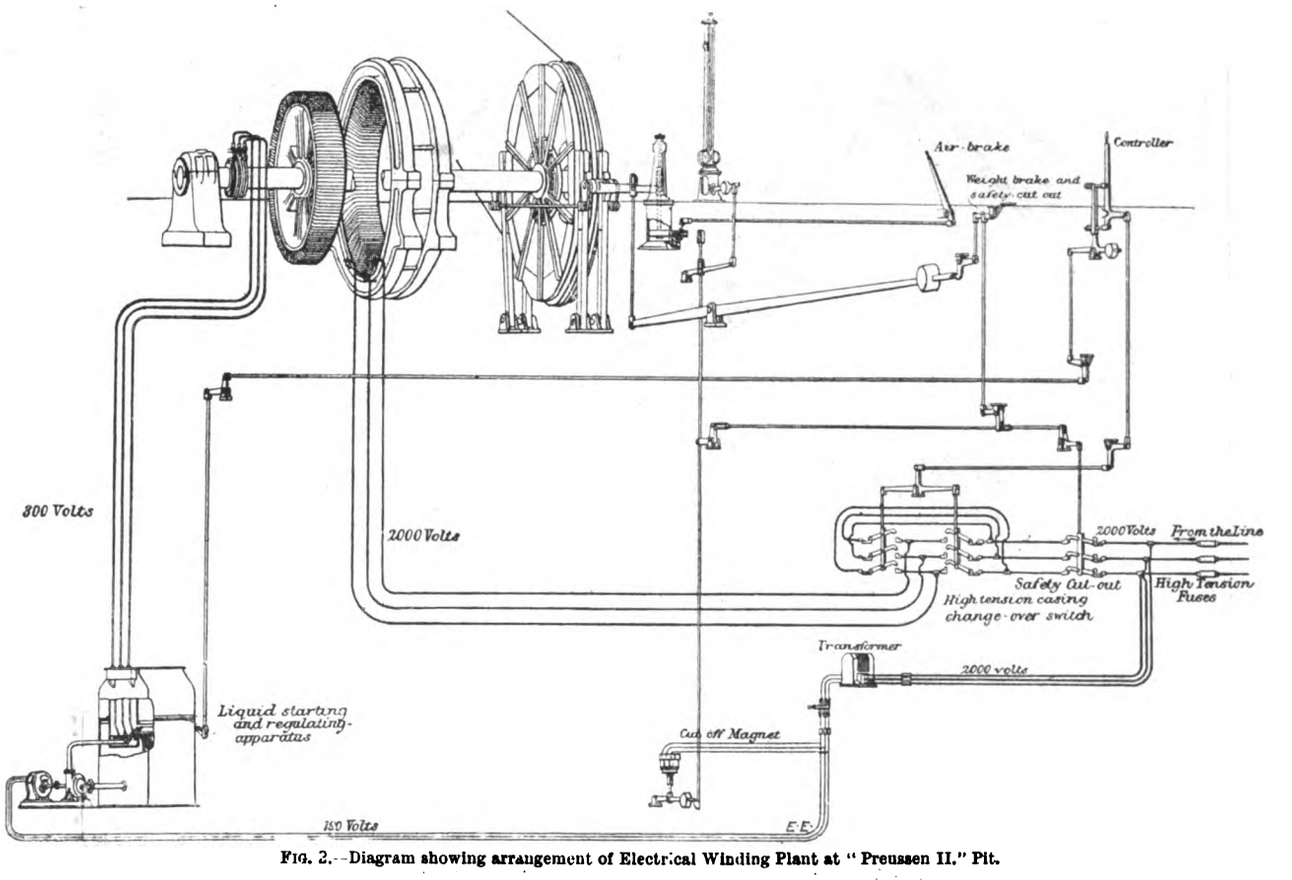

Fig. 2.—Diagram showing arrangement of Electrical Winding Plant at "Preussen II." Pit.

frames being of the A.E.G. patented type, with tie-rods. To drive these generators, there are installed three twin compound engines of 800 h.p. per set. The winding plant (see Fig. 1) includes a Koepe pulley of 20ft. diameter, the winding rope being 1¾in. diameter. Details of the winding are as follows:

| | |
|---|---|
| Coal lifted per journey ..... | 2 tons 3cwt. |
| Speed (for coal) ..... | 52½ft. per second. |
| Speed (for miners) ..... | 16ft. per second. |

The winding cycle for coal is:

| | | |

containing tank shown, with which is combined a reservoir below. Through both of the latter there is kept up a constant circulation of soda solution, and as soon as the regulating valves at the bottom of the upper vessel are shut the liquid begins to rise, and allows a passage of current between the resistance plates, thus speeding up the motor. The higher the liquid rises and the greater the surface of the plates covered, the smaller becomes the resistance in the rotor circuit, and therewith the speed of the motor advances towards its full value, which occurs when the liquid has reached the overflow point.

The actuation of the regulating valves is carried out from the same hand lever referred to above, which controls the direction of rotation of the motor. After the lever sets the stator switch back or forward for one or other direction of running, it can be moved through a certain arc without the reversing switch being affected. This intermediate path allows of the adjustment of the regulating valves to bring the liquid resistance to the correct height so as to run the motor at the required speed. Only when the lever reaches a point near the mid position is the stator reversing switch again actuated and the current interrupted. A special point of the arrangement is that the rise in speed of the

Digitized by Google

motor by decrease of the resistance is also controlled by the water supply of the pump feeding the resistance, so that the driver cannot possibly start faster than the arrangement of the water supply, made with due regard to the friction of the rope on the Koepe pulley, or the overload capacity of the plant, will allow. By this compulsory graded rise of the liquid and the progressive speed which it ensures, all shock or unsteady movements at starting are entirely avoided.

In order to obtain an immediate start of the motor when the hand-lever is set out to its limit, the resistance plates are so arranged that they are always immersed to a certain depth in the liquid traversed by the current, so that on switching in the stator the necessary current to enable the motor to start traverses the rotor windings. All current-bearing parts of the plant are railed off from contact, but, at the same time, are fully visible for inspection. The braking arrangements are laid out on a plan similar to that obtaining with steam winding engines, but are yet safer. The Koepe pulley carries on either side a brake run of some 20ft. diameter, on which four brake blocks work. These can be thrown in through compressed-air gear by a hand-lever, and so serve as a brake when winding. The same brake is also thrown in, in case of overwinding, by the action of the depth-indicating gear shown in the diagram (Fig. 2), and at the same moment the emergency switch opens, thus cutting off all current from the plant. In case of accidental interruption of the current due, for instance, to the blowing of a fuse in the main leads, an electromagnetic braking device is fitted which releases a weight and so actuates the connecting rod of the compressed-air brake and opens the emergency switch. For the further contingency that the pneumatic brake might refuse to act, a reserve braking device is provided in the form of a foot-lever, by depressing which the driver can also open the emergency switch.

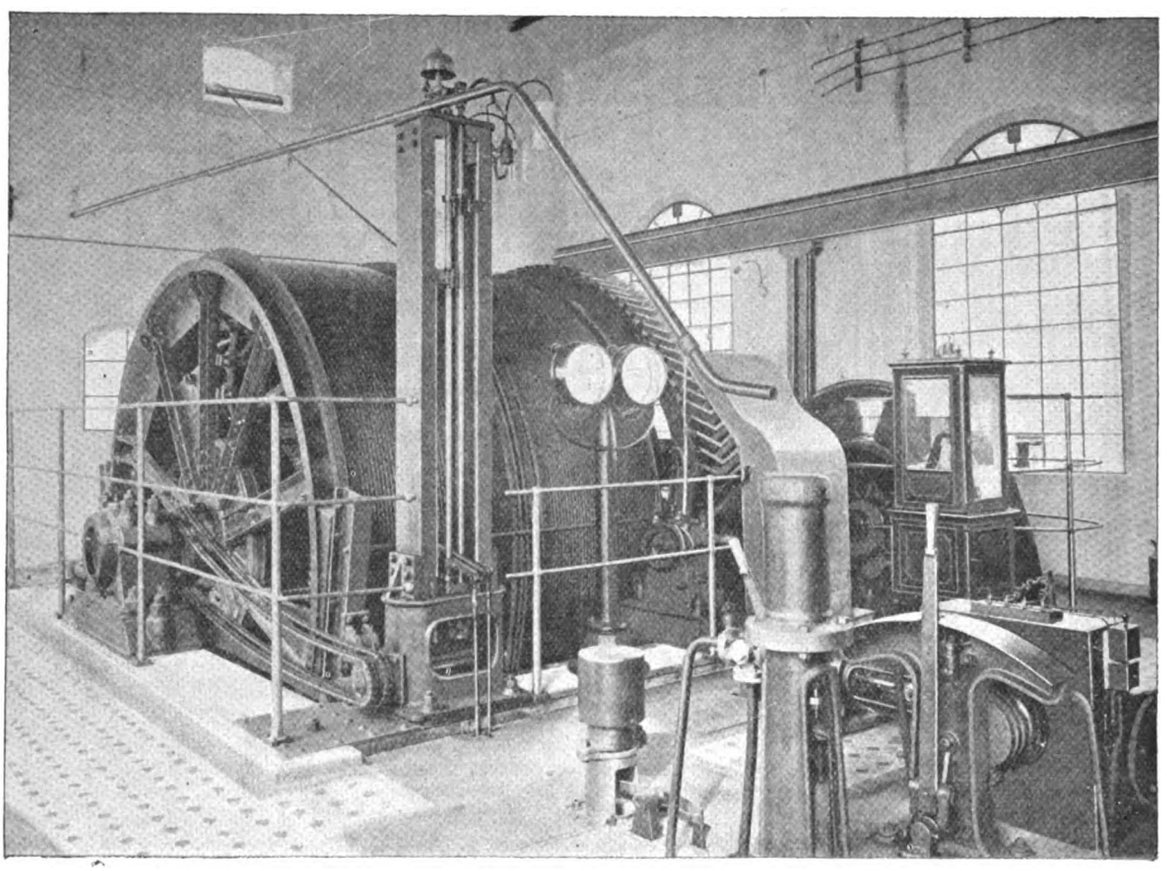

FIG. 3.—Winding Plant at the "Donnersmarckhuette" Collieries, Zabrze.

### WINDING PLANT AT THE "DONNERSMARCKHUETTE" MINES AND STEELWORKS, ZABRZE, OBERSCHLESIEN.

This plant (Fig. 3) is an illustration of the Ilgner system already referred to, with three-phase supply. Two 892-kw. three-phase machines in the power station generate current at 1,500 volts pressure, the speed of the machines being 94 revolutions per minute. These generators are direct coupled to Korting gas-engines operated by furnace gas. A third generator set is used as a reserve. On account of the speed variations inseparable from gas-engine working, the generators have "damper" windings in order to obtain perfect parallel running. They are excited with current at 220 volts. The frequency of the supply is 50 periods per second. The weight of coal lifted per journey is 1 ton 5cwt. from a depth of 1,650ft. and with a maximum speed of 16½ft. per second. The drums are each 12ft. 6in. diameter and 3ft. 7in. over-all width. The load is divided between two tubs, each weighing 7½cwt. empty, and the weight of the cage empty is five tons, it being designed to eventually take much heavier loads, according as the mine is deepened. A 1in. circular winding rope is used.

The continuous-current shunt-wound winding motor (Fig. 3) is separately excited at constant voltage from the exciter, E (shown on the diagram, Fig. 4), and runs at 150 revolutions per minute, with a normal output of 230 h.p. during winding, and an output up to 400 h.p. during starting. It drives the winding drum in this plant by means of toothed-wheel gear with reduction ratio of 1 to 6. The drum is fitted with brake blocks. Under normal working conditions the brake is actuated through compressed air by means of a hand-lever, but a drop-weight serves as a safety brake, and is actuated through the depth-indicating gear, or, in the case of the current being interrupted, by a magnetic brake, BM. The drop-weight is kept balanced by a compressed-air cylinder, but can also be released by hand.

The Ilgner converter plant includes a three-phase induction motor connected to the supply mains, giving at a theoretical speed of 500 revolutions per minute an output of 125 h.p. It will be noticed, therefore, that while the winding motor must work up to 400 h.p, the three-phase induction motor in this case is only of about one-third this output. The induction motor is coupled by means of a flexible coupling to a shaft carrying a cast-steel flywheel, weighing 15 tons, with a diameter of 11ft. (maximum peripheral speed about 280ft. per second), and mounted on the same shaft is a compensated continuous-current generator (Déri system) for an output of 72 kw. Beyond the left-hand outer bearing is an exciter set consisting of an 8-kw. 220-volt compound-wound machine, which excites the

Digitized by Google

fields of the continuous-current generator and the winding motor. The starting and speed control of the winding motor is effected by means of the Leonard system, already referred to, by alteration of the excitation through the reversing and controlling switch, R C R, as shown on the diagram (Fig. 4). One of the special features of the switching arrangements in this system is that the controlling lever of the resistance, R C R, is so designed that for each position to which it can be put by the driver there is a definite fixed speed for the winding motor, no matter what the load may be which is being lifted or lowered. Also, the driver can electrically brake the winding motor either quickly or slowly by suitably adjusting the lever so as to make the winding motor run as generator, and so help to speed the flywheel.

The Ilgner converter works in the manner described below. The energy in the form of three-phase current from the network is brought to the induction motor coupled to the flywheel and continuous-current generator. The latter, especially when the winding motor first begins to run, must commutate a current many times greater than the normal full-load current, with almost no volts pressure and with the brushes in neutral position. For this reason its having given off some of its energy; in other words, it is made capable of again supporting the demands of the winding motor. The flywheel has the further advantage that it safeguards the plant against any breakdown due to a fuse in the station or circuits giving out, as it alone has sufficient energy stored in it to drive the generator, C C G, for a considerable time. The speed variations of the converter in this installation lie between 490 and 432 revolutions per minute.

In order to produce these flywheel effects over the necessary range—that is, in order to ensure that the energy taken up by the three-phase motor from the network will not exceed a certain figure, carefully designed in each case with regard to the working conditions of the winding—the liquid starting resistance, S S R, used for the induction motor is provided with an automatic "slip" regulation, depending in action on the current being taken from the mains. This works in such a manner that at the moment of starting of the winding machine—that is, at the moment when the tendency of the motor is to take a higher current than its normal current—resistance is automatically inserted in the rotor, and *vice versâ* when releasing the load, during the slowing down and changing periods of the winding—

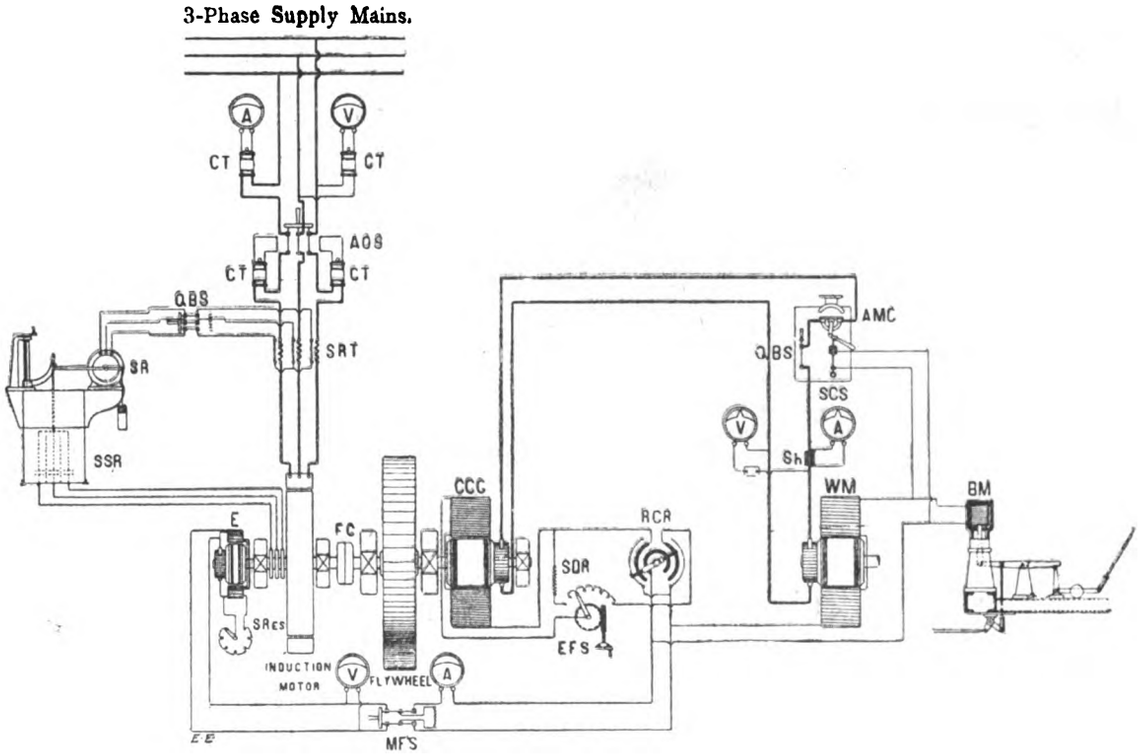

FIG. 4.—Diagram showing arrangement of Electrical Winding Plant at the "Donnersmarckhuette" Collieries. A, ammeter; A O S, automatic oil switch; A M C, automatic maximum cut-out; B M, magnetic brake connecting with compressed-air brake and depth-indicating gear; C T, current transformer; C C G, continuous-current generator (compensated Deri system); E, exciter; E F S, emergency field switch; F C, flexible coupling; M F S, main field switch; Q B S, quick-break switch; R C R, reversing and controlling resistance; S R, "slip" regulator; S R T, "slip" regulator transformer; S S R, starting and "slip" resistance; S C S, short-circuiting switch; S D R, spark discharge resistance; S Res, shunt resistance; Sh, shunt; V, voltmeter; W M, winding motor.

a so-called "compensated" continuous-current generator (Déri system) is used, and in this machine, by means of a special winding, any cross magnetic action of the armature is completely negatived, and perfectly sparkless working is attained for all loads and voltages.

The converter serves two purposes; firstly, it converts the high-tension three-phase current to continuous current; and, secondly, its still more important function is to secure an almost complete avoidance of the otherwise heavy "peaks" of current on the supply mains, brought about through the starting of the winding plant, and to thus make the actual current demand on the supply works uniform, and also proportional to the load dealt with by the winding plant. This is effected by the arrangement that at the starting of the winding motor and during its acceleration period the extra demands of the winding motor are supplemented by the energy stored up in the flywheel which drives the generator, C C G, and assists the induction motor. During the changing intervals and periods of slower or less loaded winding the supply from the power station is used in order to again accelerate the flywheel, which has meanwhile been slowed down due to that is, when the current tends to decrease the resistance is automatically diminished. As a result of this insertion of resistance, not only is the "slip" increased (up to about 12 per cent.), in other words, not only is the flywheel slowed down and forced to give up a considerable store of its energy, so helping to drive the generator, C C G, feeding the winding motor, but also as the resistance of the rotor circuit is increased in proportion as the speed falls, the rise in current in the induction motor is impeded. At the speeding up of the flywheel when the load on the winding motor is reduced, the reverse action takes place, when, by the gradual switching out of the resistance, a sudden sinking of the current in the induction motor below its normal value is prevented and it is gradually sent up again to its correct speed. In order to bring the converter set to a stop quickly when required, a brake block is arranged below the flywheel rim, and this can be applied by means of a hand-wheel and spindle and is fitted with water cooling, conveniently controlled by a tap near the brake spindle. The converter set is kept continually running during the hours of winding.

All necessary precautions, such as maximum cut-outs,

Digitized by Google

fuses, emergency switches, etc., as shown on the diagram (Fig. 4) in addition to the brakes already mentioned are provided. The switch, E F S, has for its object the immediate cutting out of the field excitation of the generator, C C G, in order to be able, if necessary, to stop the winding motor at once by this means. Near to the driver is also erected a cast-iron column bearing the ammeter and voltmeter, etc., which guide him when starting up, together with the pressure gauge to indicate whether the correct air pressure is available for the brake.

The important ends which are therefore achieved by this system, in addition to the advantages already mentioned, are as follows: (*a*) that while the current from the generator, C C G, to the winding motor, W M, will have to vary over a very wide range, and will have heavy "peaks" at the starting and accelerating periods, the current from the supply mains to the induction motor but very slightly oscillates above and below a constant value during a given winding cycle, and is proportional to the load being dealt with by the winding motor; (*b*) that the starting and stopping of the winding motor takes place with practically no loss of energy.

COAL MINES, GRAND HORNU, BELGIUM.

In several respects the installation at these mines esembles that at "Preussen II." pit already described. Three-phase current is generated at a pressure of 1,250 volts, and with a frequency of 23½ periods per second, being distributed by means of underground cables to the different high-tension motors.

In the power station there are installed two three-phase generators, one being designed for an output of 2.000 kw. at 88 revolutions per minute (flywheel effect, 4,100 foot-tons), and the other for 4,000 kw. at the same speed (flywheel effect, 11,200 foot-tons). These generators are driven respectively by a Carels tandem engine (Sulzer system) and a Carels double-tandem engine. A paralleling switch is provided for transferring the load from one set to the other. Jet condensers are installed, the double-tandem engine being provided with two separate plants, so that either half can be run as a simple tandem machine. The condensers work in conjunction with a water cooler of 130,000 gallons capacity, feed water for the boilers being taken from the condensers through an oil filter. The A.E.G. feed pump has a capacity of about 44,000 gallons per hour when running at 225 revolutions per minute, and is driven by a motor wound for 1,150 volts pressure. Körting injectors serve as a reserve for boiler-feed purposes. There are six Meunier boilers installed in the boiler-house, each having a heating surface of 2,000 square feet. Steam is generated at 140lb. pressure and superheated to 260deg. C.

In addition to the main generators, a three-phase direct-current transformer set has been installed. This consists of a three-phase motor wound for 1,200 volts, and a frequency of 23½, designed for an output of about 330 h.p. at 460 revolutions per minute, direct-coupled to a continuous-current dynamo on either side. One of the latter—a shunt-wound machine capable of an output of 90 kw. at 230 volts—is connected to a balancer, serves to supply exciting current at 110 volts, and maintains a pressure of 2 × 110 volts between the outers of the three-wire lighting network. The other, a compound-wound machine capable of an output of 130 kw. at 600 volts, supplies current to an electric locomotive used for haulage purposes, besides to a small power transmission system.

In order to maintain the exciting current at a constant pressure, a buffer battery of 130 cells is connected in circuit with the outer leads of the shunt-wound dynamo. This battery has a capacity of 144 ampere-hours for three hours, and also serves to supply starting excitation for the three-phase generators. Two dynamos wound respectively for 220 volts and 600 volts, belt driven from a steam-engine placed in an adjoining room, are provided as a reserve for this transformer. The main switchboard is erected on a gallery and consists of 12 panels. All the high-tension gear is placed in the basement. Both generators are provided with oil switches, and all high-tension cables are connected to the switchboard. The current passes through remote-control cut-outs, which can be operated from the main switchboard by means of press-buttons.

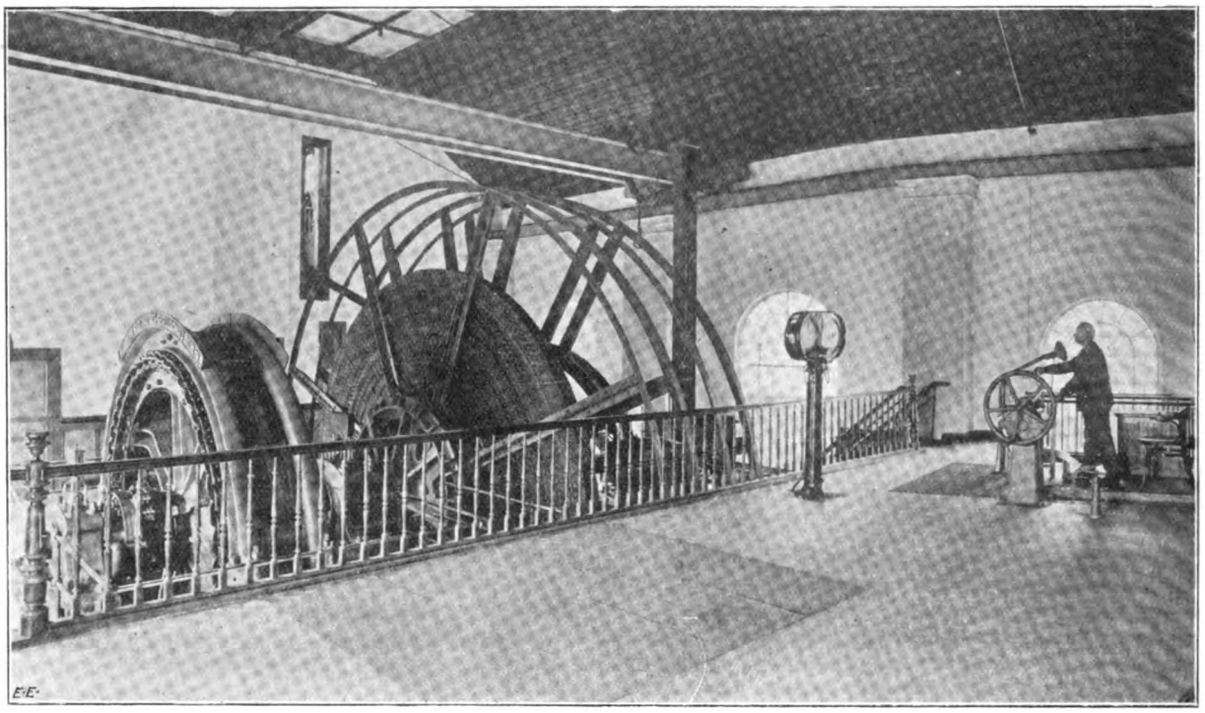

FIG. 5.—Winding Plant at the Grand Hornu Collieries, Belgium.

Supply is given to three main winding engines. These work on the bobbin principle, a pair of drums (Fig. 5) being provided for each shaft. Flat tapered winding ropes are employed. For the winding motor, the special form of liquid starting resistance as described in connection with "Preussen II." pit is used, the motor being direct connected, and the controlling arrangement in general as for "Preussen II." p't. Details of the winding are as follows

*For each of the Shafts VII. and XII.*

| | |
|---|---|
| Coal lifted per journey | 2 tons 12cwt. |
| Total lift (including rope) | 14 tons 6cwt. |
| Coal lifted per hour | 65 tons. |
| Depth | 3,300ft. |
| Max. speed (reducible to 20in. per second) | 45ft. per second |

The winding cycle (for coal) is as follows:

| | | | |
|---|---|---|---|
| Starting | 15 | seconds | 144 seconds. |
| Normal full speed | 78 | ,, | |
| Slowing | 12 | ,, | |

| Coal lifted per hour | 56 tons. |
| Depth | 1,864ft. |
| Maximum speed | 41½ft. per second. |
| Revolutions per minute of winding drum | 43. |

It should be mentioned that other services in these mines, such as pumping, ventilating, coal screening, etc., are also worked electrically, and absorb about 1,000 h.p.

We note that "Preussen II." pit is to be visited by the Verband Deutscher Elektrotechniker during their forthcoming annual meeting, June 4-8.

## THE BERLIN-ZOSSEN TESTS AND THEIR RESULTS.*

An interesting paper on this subject was presented by his Excellency Dr. Schulz, president of the Imperial German Railway Department, also chairman of the German investigation committee (Studiengesellschaft) on high-speed electric railways. It was in this second quality that Dr. Schulz presented the report upon the experiments on the Berlin-Zossen road. The investigation committee on high-speed electric railways was organised at Berlin in 1899, and in the trial runs speeds of 200-210 km. (124-130½ miles) per hour were reached, velocities far exceeding any other speeds before attained. The permanent way, consisting of steel rails 12m. long, each carried on 18 wooden ties, had a total weight of 224 kg. per metre (454·5lb. per yard), including the guard rails. There were no curves of a radius smaller than 2,000m., and the super-elevation of the outer rail was 80mm. The grades were few and inconsiderable. The experiments proved that the standard type of permanent way, when sufficiently strengthened, is amply sufficient for speeds of 200 km. per hour and more. The two motorcars were of similar design to the latest types of European express train cars. Each car had accommodation for 50 passengers, with a length of 22m, two trucks of three axles each and of a wheel base of 5m.; the total weight was 90 tons, uniformly distributed over the axles. Even at a speed of 210 km. per hour the cars ran quite smoothly. This experience proves, in the words of Dr. Schulz, "that the general design of our express train cars can be applied to extra high speeds, if the wheel base is increased accordingly. It will be possible in future construction to reduce the dead-weight of the cars."

Dr. Schulz then described the collecting devices, which are familiar to the readers of this paper, and which he said gave excellent success, and which "safely supplied the cars running at a speed of nearly 60m., or 200ft. per second, with as much energy as 2,000 kw., and this even in unfavourable weather." The motors were designed for a normal output of 250 h.p. each, and overload capacity of 750 h.p., and were coupled directly, or by means of a spring coupling, to the driving axles. The trials showed that motors for a three-phase current are well suited for the operation of high-speed trains on main lines. To determine whether the motors could be run directly by the high-tension current, Siemens and Halske built an electric locomotive fitted with two motors for a tension of 10,000 volts. This locomotive with a dead-weight of 40 tons, coupled to a train of 70 tons, reached a speed of 100 km. per hour; when coupled to a train of 100 tons, 50 km. per hour were made as a regular run. The current had an E.M.F. of 8,000-11,000 volts and 40-48 cycles. These motors gave satisfactory results on the trials.

*Train Resistance.*—The total resistance in the car, consisting of the different kinds of mechanical friction and of the air resistance, was measured, and the following results were obtained: (*a*) The friction resistance was found to be not more than 1·5 kg. per ton of weight of the car at a speed of 5 km. per hour. It slowly increased as the speed increased, and reached 300 kg. with a speed of 200 km per hour. (*b*) The air resistance increased much more and at a much higher rate with the increase in speed. The numerous observations gave the uniform result that the air pressure on one square metre of front surface, or that measured at right angles to the direction of travel, is equal to the square of the velocity in kilometres per hour multiplied by the constant 0·0052. Assuming 7·5 square metres to be the front area of a car, the air pressure on this surface with different speeds was as follows:

| | | | |
|---|---|---|---|
| At | 50 km. (31 miles) per hour | | 98 kg. |
| | 100 ,, (62 ,, ) | ,, | 390 ,, |
| | 150 ,, (93 ,, ) | ,, | 878 ,, |
| | 200 ,, (124 ,, ) | ,, | 1,560 ,, |

The air pressure on the sides of the car is relatively small, and depends a great deal on the direction and strength of the wind. The air suction on the rear of the car has no importance, and does not increase much with increasing velocity. The air resistance on the car might be reduced by giving the car a parabolic head; if, however, the train speed should be increased considerably above 200 km. per hour, the air resistance would increase at least to such an amount that the motors in the cars would no longer be able to supply the necessary power to overcome it. Dr. Schulz states, therefore, that it is the air resistance which determines the limit of the attainable speed. The resistance of a trailer is considerably less than that of a motorcar, for the greater part of the front area of the second car is covered by the first, and it was observed that the air resistance on the trailer was but one-seventh of that of the motorcar. The amount of energy, the current and the voltage applied were observed at the feeding point, of the experimental line, and also in the car itself. On the level and with no wind, the following average values were obtained for a motorcar weighing 80 tons:

| Speed | | Energy supplied. | Output. |
|---|---|---|---|
| Km. | Miles. | Kw. | H.P. |
| 100 | 62 | 193 | 218 |
| 150 | 93 | 546 | 613 |
| 200 | 124 | 1,190 | 1,340 |

With trailers weighing 40 tons, and with an accommodation for 50 persons, the output for the same speed was only 49 h.p., 116 h.p., and 233 h.p. Hence it follows that it is considerably more economical to care for a crowded traffic by means of trains consisting each of several cars than by many single motorcars of the same capacity running in short intervals, although the latter would be much more desirable for the conditions of general traffic.

*Brakes.*—Westinghouse air-brake equipment and hand brakes were used. The brake shoes were hollow, and were cooled with water to prevent the rims and the brake blocks from becoming overheated. At speeds of 170 km. and 180 km. the brakes stopped the car within a distance of 1,300m. and 1,400m., which corresponds to an average retardation of nearly 1m. per second². The admissible retardation can be increased to 1·5m. per second², without danger to the passengers, by raising the brake pressure, whereby trains running at speeds of 160 km. and 200 km. per hour can be stopped within 660m. or 1,000m. For speeds of more than 120 km. per hour the signals in cloudy weather could not be seen sufficiently soon. This was remedied by an electromagnetic device arranged in the car, which, by means of contacts along the line, presented a red disc before the eyes of the driver when the signal was at danger. This device has never failed, even at the highest speeds.

*Conclusion.*—In conclusion, Dr. Schulz makes the following remarks on the subject of safety: "As at the introduction of the steam locomotive, danger to the health of travellers was feared from very high speeds before these electric tests were conducted. I can state, however, from my own experience, that the passengers were in no way affected by the speed of 200 km. per hour or more, which we often reached. Each engineer was at his place, occupied in making his observations, and the silence in the car was only interrupted every 10 seconds by a bell signal to take readings on the instruments. The duty of the engineer, however, was more arduous, as he had uninterruptedly to observe with the greatest accuracy the run of the car, the line, and the signals. Surrounded as we were by apparatus and wires which carried a current of 14,000 volts, we, nevertheless, felt per-

* Abstract from the *Street Railway Journal* of paper read at the meeting of the International Railway Congress at Washington, May 11, 1905.

Digitized by Google

fectly safe; no personal injuries were ever sustained in spite of the short-circuits which occasionally occurred. It was possible during the run to observe the scenery comfortably, but persons standing on the platforms of the stations we passed could hardly be recognised. No injurious effects due to air pressure were ever felt when trains passed on the neighbouring line, and spectators standing near the line had no uncomfortable sensations. More than 300 runs were made, and all without a single accident. Nobody was killed or injured, and no damage to property occurred. Bloody remains, however, of small birds who were killed were observed on the front of the car. These birds, doubtless, thought they could avoid the approaching train, but the electric car moved faster than any bird can fly, and killed them. These were the only accidents that happened.

"The investigation committee on electric high-speed railways has thus accomplished its work; the conditions have been determined under which electric main railways can be operated with high speeds, and it has been proved that such operation is not more dangerous than the present railway practice. Here is a vast field for work open to railway men associated with electrical engineers, and may the time not be far off when a real high-speed electric railway will be an accomplished fact!"

## ELECTRIC TRACTION IN FRANCE.*

BY F. PAUL-DUBOIS, ENGINEER OF ROLLING STOCK AND MOTIVE POWER, ORLEANS RAILWAY OF FRANCE

Reviewing the status of electric traction in France, the author points out that the system of continuous-current traction with third rail can now be considered as well established, and leaves but little to be desired from the technical point of view, although further improvement is always possible and desirable. Continuous-current motors are economical, convenient, and reliable. The system of electric traction by direct current, however, has one very grave defect for railroad operation, as it is not suited to the use of high-voltage currents. Up to the present, hardly anything beyond 700 volts has been used in practice for operating continuous-current motors for traction, and the transmission of energy at such a moderate voltage results in a prohibitive cost for the mains as soon as the amount of energy or the distance over which it is to be transmitted become at all large. From this point of view there is a radical difference between tramways and railways. The method usually adopted for railways has been the use of transformer sub stations receiving a supply of high-voltage current from a central station and feeding the different sections of line with continuous current. This system has been applied more particularly on the line from Les Invalides to Versailles, on the line from the Quai d'Orsay to Juvisa, and on the Paris Metropolitan, and is to be applied on the extension of the Fayet-Chamonix line to the Swiss frontier. This arrangement, which at present is in general favour, makes it possible to extend the field of action of continuous current very largely. It would evidently be a great advantage from the economic point of view to increase the voltage at which the energy is transmitted and at the same time reduce the number of connecting links between the central station and the motors on the trains.

Numerous attempts in this direction have been made. Some of them are also based on the use of continuous-current motors. As belonging to the latter class, may be mentioned the "three-wire" system applied in France on the Grenoble-Chapareillan tramway, and on a section of the St. Georges de Commiers-La Mure. This system, which makes it possible to double or even quadruple the voltage of distribution while retaining the same voltage at the motor terminals, can be installed in several ways, either with a single wire divided into sections of alternate polarity, which makes it necessary to distribute the trains so that the load on all sections is practically the same, a condition which is impracticable on railways, or with two wires, one positive and one negative. In both cases the track performs the office of a neutral wire.

In the two applications made in France, the motors on the same vehicle are connected on opposite sides of the three-wire system, so as to balance the demand for energy. The lines in question, which are single-track lines, have two insulated conductors, showing a difference of potential of 1,200 volts in the first case and 2,400 volts in the second; the motorcars of the Chapareillan line have two 600-volt motors in series, and the La Mure locomotives have four motors of the same voltage also connected in series.

The use of 2,400 volts in the distribution has the result of reducing the loss in the mains to one-quarter of what it is with the ordinary voltage. Thus there is already a considerable economy in the first cost of the conductors.

However, this solution has its defects. In the first place, there is the complication of having two conductors at different voltage, particularly at switches and at crossings; then the motors have to be coupled up permanently in series, and consequently the "series-parallel" control has to be abandoned; finally, as there may be a difference of potential of as much as 1,200 volts between the different parts of the locomotive and the ground, there is greater difficulty in maintaining the insulation, particularly that of the motors.

*Polyphase Current Motors.*—Up till lately the only alternating-current motors capable of being utilised for traction were asynchronous polyphase motors. These motors have received in Europe, principally in Italy and Switzerland, a certain number of applications, some of them being important ones. The type generally used is the three-phase. On the Valtellina line the current is supplied at 3,000 volts, and on the experimental Marienfelde-Zossen line even at 10,000 volts. Although these motors give an interesting and advantageous solution in certain cases, they do not appear capable of general application. Against them, in the first place, is the fact that each track requires at least two working conductors at different voltages, and even three if the track rails are not used as a conductor; the resulting complication becomes very inconvenient at switches and crossings; moreover, the maintenance of the insulation becomes more difficult. Then the polyphase induction motor is essentially a constant-speed motor; any other speeds than those near synchronism can only be obtained at the cost of rheostatic losses, or by means of more or less complicated devices, the usual one being that known as "concatenation." This latter arrangement makes it possible to obtain a good efficiency at two different speeds, but its realisation is not without practical difficulties. With motors of this type the power stations and the lines carrying the current must have a greater capacity for an equal service than with continuous-current motors, owing to the greater power required, both in order to haul trains up gradients without reduction of speed, and also for starting, and, again, owing to the comparatively low power factor of three-phase traction systems. This increased capacity results in a corresponding reduction in efficiency, which is all the greater because it is not possible in this case to reduce the variations of load by using accumulators, so that the amount of energy consumed, other things being equal, is about the same as in the ordinary system with continuous current and transformer sub-stations. Hence the cases in which the system of three-phase motors is distinctly superior are comparatively rare. It may be stated in a general way that the conditions most favourable to its use are when the lines are long, when there are long intervals between the trains and they have few stops, or when the lines have long and regular gradients, particularly if there is plenty of motive power, and it is cheap; under such conditions it is cheaper both to instal and to maintain than the preceding system. In the case of mountain railways, three-phase motors have another valuable advantage, which is the automatic limitation of the speed and the return of the energy to the line while running down hill, when the motors act as generators. The existing applications of polyphase motors to traction mostly belong to one or other of these classes.

*Single-Phase Current Motors.*—A much more extended field seems to be available for single-phase alternating-current motors, long forgotten in this connection, but which recent improvements have once more brought into notice. The only monophase alternating-current motors at present existing which have the speed and torque properties suit-

* Abstract from the *Street Railway Journal* of a paper read before the International Railway Congress.

Digitized by Google

able for application to traction are the "commutator" motors. The question of applying motors of this kind to traction purposes has lately been taken up in several different countries simultaneously—thus in America by Mr. Lamme, in Italy by Mr. Finzi, in Germany by Messrs. Winter and Eichberg, in France by Mr. Latour. The motors tried are either of the series type with laminated poles, or of the repulsion type, or are a combination of both these types. The results already obtained raise the hope that it will not be long before there will be a monophase motor which will work satisfactorily, give a good torque at starting, a high power factor under normal conditions and an efficiency similar to that of the best continuous-current motors. Under these conditions the simple alternating-current motor is of very great interest, but it is necessary to wait for further results before any definite conclusions as to this system can be reached.

*Summary.*—In summarising the situation, the author believes that the use of electric traction on railways is already practicable in all cases where its use would be considered advisable from the economic point of view. Short-distance passenger traffic seems to offer the most favourable field for electric traction. Moreover, it is almost exclusively to this class that the applications already made on railways belong. Electric traction for freight trains exists only as an exception justified by peculiar local conditions. It may be said in a general way that in services of this kind the economy of the system increases with the reduction in the weight of the trains and with the increase in their number. Leaving out of consideration metropolitan railways, which form a special class for which electric traction is now a necessity, the suburban lines of some large towns may offer conditions favourable to the use of electricity. The latter, in the case of service with many stops, has the great advantage that it makes it possible to increase the average speed materially, owing to the rapidity of starting electric motors. The absence of smoke, the better lighting of carriages and stations are other advantages, which, although only of a secondary character, yet also contribute considerably to the general improvement of the service.

Similar conditions will be found to occur on sundry busy lines connecting large centres not very far apart in industrial districts, where the service must assume as nearly as possible the character of a tramway service. On lines of this kind, and even on certain secondary railways, the increased facilities of transport made possible by electric traction may lead to important increases in the traffic and in the receipts. Another case where the adoption of electric traction is worthy of consideration is that of lines which are worked up to their full capacity. For electric traction indeed makes it possible, under certain conditions, to increase the capacity for traffic, while avoiding more costly measures, such as quadrupling the track or enlarging the terminal stations. This possibility is due, in the first place, to the greater speed of the train, resulting from quicker starting and less loss of speed up gradients; and, secondly, to the reduced blocking up of the terminus stations owing to the smaller number of operations necessary to receive a train, and then clear the siding for the next train.

The great capacity of electric motors is especially advantageous on mountain railways, whether adhesion or rack railways. An electric locomotive need not weigh more than 40 kg. to 50 kg. per horse-power (89lb. to 112lb. per British horse-power), and the equipment of a motorcar not weigh more than 20 kg. to 25 kg. per horse-power (45lb. to 56lb. per British horse-power). Electric traction, moreover, makes it possible to obtain the maximum adhesion by making all the car wheels driving wheels. It therefore makes it possible to locate lines with sharper curves and steeper grades (for instance, the Fayet-Chamonix line, Paris-Lyons-Mediterranean Railway), which are cheaper to build. The saving effected may in some cases be so large as to cover, or even more than cover, all the additional expenditure for the installation of power stations and transmission lines.

The relative lightness of electric vehicles also makes them suitable for obtaining very high speeds. The large amount of power required to run a train at from 150 km. to 200 km. (93 miles to 124 miles) per hour can more easily be furnished by electric motors fed from outside than by a steam locomotive, the weight of which increases rapidly with the speed to be attained. The recent experiments made in Germany have proved (if, indeed, it was necessary) the superiority of electricity from this point of view.

The most serious objection to such a great increase in speed is the expense. In the first place, on very busy lines, which alone could serve as a motive for the use of high speeds, it would be impossible to run trains at 200 km. (124 miles) per hour, between ordinary trains, without disturbing the whole time-table and making the ordinary traffic impossible. It would, therefore, be necessary to build new lines, either by adding new tracks to the existing ones, or, better, by building entirely new lines with curves of large radii and a wider road-bed so as to have a greater distance between trains. The track itself would have to be strengthened materially. In the interests of safety it would also be necessary to absolutely prohibit level crossings, junctions, and other dangerous features. Taking it altogether, such a road would cost much more than the existing lines, quite apart from the electric equipment. Moreover, as a high-speed line would also be of considerable length, for it would scarcely be worth while to incur such a large expenditure merely in order to save one-quarter or half an hour on a journey, the capital required for construction would be enormous.

To earn dividends on such a capital and to meet the working expenses, which also would be very high, were it only on account of the great increase in tractive effort at higher speeds, one could only depend upon passenger traffic, and, perhaps, on some additional receipts from parcels traffic. No doubt cases will occur, sooner or later, where the development of the communication between two large centres may justify, from the economical point of view, the building of such a line. But in France, at least, this case does not seem to be likely in the immediate future.

*Conclusions.*—On the whole it seems to us that electric traction should at present be looked upon as a useful auxiliary to steam traction, capable of operating certain parts of railway traffic with advantage and economy. The principal cases in which its adoption may at present be feasible are: firstly, on lines which are chiefly underground, then on metropolitan and on suburban lines, on interurban lines of limited length and with much traffic, on railways with steep gradients, and on lines which are worked up to their full capacity.

It is impossible to indicate in a general report in any more definite a way the cases in which the system of working may lend itself to the application of electricity; it is essentially a question of degree, and each individual case requires special examination. In this examination special consideration must be given to the cost of the electric equipment, the principal factors of which are, in the first place, the conditions of working, the number and weight of the trains, and, secondly, the conditions under which the line is built; its length, profile, and plan; then the charges for interest and sinking fund of the capital outlay required must be compared with the economy which electric traction will give as compared with steam traction.

If it is a question of a new line, the adoption of electric traction may in certain cases result in a lower cost of construction, whereas in the case of existing lines the value of the rolling-stock which will be rendered useless by the introduction of electricity has to be taken into consideration and written off. Among the conditions in favour of electric traction are naturally the proximity of easily utilisable water power or of other cheap sources of energy, such as coal pits and blast furnaces.

In comparing the cost of traction, we must allow in the case of electricity, in addition to the eventual economy realised in the production of energy, for the reduction of dead weight resulting from the smaller weight of electric locomotives, the reduction in the cost of driving and of maintenance, as well as for the accessory economies capable of being effected in shunting operations at stations, in lighting the stations and trains, etc.

Finally, if so happens, the increased receipts which may result from the improved service have also to be taken into consideration. In any case, the problem becomes in the end a financial and economic one.

In an appendix Mr. Paul-Dubois gave an extended account of electrified steam roads in Europe, to which reference has been made above.

## THE INTERNATIONAL RAILWAY CONGRESS.

The two papers which we reproduce in abstract in this issue by Messrs. F. Paul-Dubois and Dr. Schulz were discussed before the International Congress at Washington, with two other papers. The first of these was by Mr. W. D. Young, who dealt with the progress of electric traction in the United States. Mr. E. Gerrard took up the same subject as far as Great Britain and Belgium are concerned, and to his paper some information was added by Mr. Victor Tremontani as to the progress of electric traction in Italy. In the discussion which followed some most interesting opinions were expressed.

Amongst the speakers from England was Mr. J. A. F. ASPINALL, of the Lancashire and Yorkshire Railway, who gave some details as to the electric line from Liverpool to Southport. Electric traction was not adopted on this line for the sake of economy, but to increase the receipts. Since the 12 months during which the line has been operated electrically the results are most satisfactory as to increase in traffic, but the operation is more expensive than with steam. The cost of coal per ton-mile especially is greater; the running expenses, however, are less, because of the greater mileage run by the crews. After describing the trains and service, Mr. Aspinall explained that one of the reasons for introducing electric traction on the line was the necessity of decreasing the crowding of the Liverpool terminus during the busy hours; the handling of an inbound steam train and its redispatching requires four distinct switching operations and eight signal operations, while for an electric train two switching and four signal operations are sufficient. It has, therefore, just doubled their terminal capacity. Further, as their terminal facilities for handling traffic on four tracks has increased, they are enabled to do all their passenger work on two tracks, leaving the other two for freight. Since electrification, however, the traffic has increased so much that they are preparing all four tracks for using electricity. The cost of the electric installations on the Liverpool and Southport line was as high as £20,000 per mile, or about 3½ times the installation of a steam locomotive service. If the interest and sinking fund charges of this sum are added to the cost of operation, it is not surprising that electric traction costs more than steam. Mr. Aspinall added that the weight of electric equipment of the trains on the Liverpool Southport line is not less than the weight of corresponding locomotives, and that the same will hold true for trains on main lines.

A discussion followed on the question of high-speed railways. Mr. T. H. LAURENT, of the Paris-Orleans Railway, commented upon the enormous consumption of energy required on the Berlin-Zossen trials. In order to run at 125 miles per hour on the level with a single motorcar weighing 30 tons and carrying 50 passengers, no less than 1,340 h.p. was needed. On his railway, with the high-speed trains running at from 62 to 75 miles per hour, a train carrying 400 first-class passengers was pulled by a 1,200-h.p. to 1,300-h.p. locomotive. He raised the question as to whether the economical problem of running such a high-speed service could be solved.

In reply, Dr. SCHULZ gave some information as to the proposed high-speed line between Berlin and Hamburg. He considered that the scheme was commercially feasible, and there were two large firms seeking the concession. The distance between the two cities is 179 miles, and the trains now took 3½ hours to do the journey. It is proposed with the high-speed line to do it in 1½ hours.

Mr. A. WILSON, of the North-Eastern Railway Company, gave some information on the use of electric traction on the suburban lines of that company near Newcastle-on-Tyne. He also furnished some data on the cost of operation of these lines, stating, however, that there was considerable difficulty in making a satisfactory comparison with steam traction. Electricity permits a better utilisation of the existing lines, and experience shows that the improved service which follows generally leads to increased receipts. The cost of electric traction for the month of February, 1905, was as follows:

| | |
|---|---|
| Mileage of trains | 92,541 |
| Mileage of cars | 254,938 |
| Average number of cars per train | 2·75 |
| Total energy consumed (kilowatt-hours) | 647,140 |
| Energy consumed per train mile (kilowatt-hours) | 6·993 |
| Energy consumed per car mile (kilowatt-hours) | 2·538 |
| Average cost of power per car mile (pence) | 1·601 |
| Engineer's pay per car mile (pence) | ·297 |
| Conductor's pay per car mile (pence) | ·217 |
| Total cost of traction per car mile (pence) | 2·115 |
| Total cost of traction per train mile (pence) | 5·7 |

In another discussion at the same congress, Mr. WILSON said that his company operated for the past year an electric suburban service in the Newcastle district with the object of regaining the traffic from the competing tramways and to increase its amount. All the traffic has not been regained from the tramways, but the amount handled has been considerably increased. The reduction in expenses has resulted in a net revenue which more than covers the interest on the extra cost of installation necessitated by the introduction of the electric power.

Mr. K. STEINBISS, of the Royal Prussian Railway, gave some information as to the running of the single-phase motors on the Niederschoeneweide-Spindlersfeld line near Berlin. The motors employed are of the Winter-Eichberg system, and the speed is from 25 to 37 miles per hour. Trains are made up of one or two auto-motorcars, with or without trailers; the heaviest train contains five cars and weighs 150 metric tons. Encouraged by the results given by this trial, German engineers are applying the same system to a line connecting Hamburg, Altona, and Blankenese, which is 15¼ miles long. The trains in ordinary service will consist of two cars, with three axles each (one two-axle truck and one independent axle), with a total of 100 seats. These trains will be run at a speed of 37 miles per hour, with three minutes' headway between trains. The work of equipping the line has been begun; it is to be opened to traffic Oct. 1 of next year.

Mr. W. D. YOUNG also gave more information on the subject of single-phase motors in order to supplement his report. He also referred to the third rail, which he did not believe was as dangerous as people said. Ten years ago there was installed in Baltimore, to avoid the third rail, a system of overhead wiring which proved very expensive, and gave a great deal of trouble, particularly in the tunnels, which extend over half the length of the line. The corrosion caused by the sulphurous smoke and vapour from the locomotives finally made it necessary to renew this line throughout. As all the changes and repairs had to be made without interrupting the service, and working with live wires, the expense was very great. Consequently his company decided three years ago to replace this overhead wiring with a third rail. This third rail is protected between stations by guard boards; at stations the third rail is entirely enclosed, except at the top, where a slot is left for the contact shoe. As an additional measure of safety, a system of automatic switches has been installed at the stations and at points where the workmen most frequently cross the tracks, but this system works irregularly, and therefore is not very reliable. Last year the line was extended across the North Baltimore Station; where passing this station the third rail has merely been omitted for a distance of 700ft., over which the trains are carried by momentum. Finally, Mr. Young pointed out the importance of the different railroad companies arriving at a definite agreement on the question of the location of the third rail. On the Baltimore and Ohio Railroad the horizontal distance between the axis of the third rail and the axis of the track rail nearest to it is 31½in.; the height of the third rail above the track rail is 3½in. This height is almost the same everywhere, but the horizontal distance varies greatly with the different companies, and it would be very desirable to make these dimensions uniform.

After discussion, the following conclusions were adopted by the congress:

### CONCLUSIONS.

The section recognises that electric traction should be

Digitized by Google

considered at present as an important auxiliary of steam traction, being capable of handling certain portions of railway traffic with advantage and economy.

It is impossible in a general exposition to point out the exact service to which electricity can be most readily applied, the application being essentially a question of local conditions, each particular case requiring special study. In this study there must be taken into account the expense of electrification, and the following points: first, condition of service—that is, the frequency and weight of trains; second, the physical conditions of the line, such as length, profile, and plan. In comparing the expenses of operation by electricity and by steam, the interest and depreciation on the electrical installation must be considered.

The increase in revenue which the improvements in service will generally produce should also be given consideration. An important point in the use of electricity is the increase in the present station facilities resulting from the reduced number of movements in the stations by the use of electric traction.

From the information furnished to the congress it would seem that with the third rail, as now used, security can be assured under favourable conditions without it being necessary to cover or protect the third rail for its entire length.

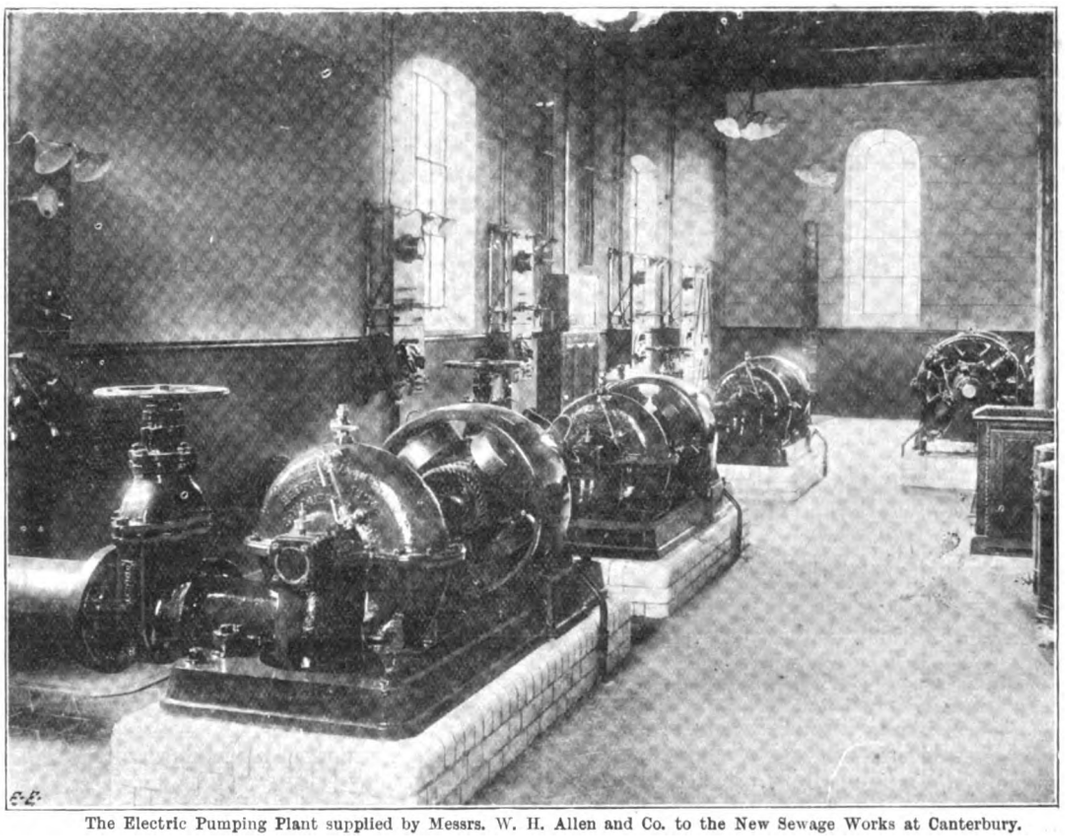
The congress has heard with much interest the results experienced with high-speed electric traction between Marienfeld, and Zossen, and also of the tests and first application for traction purposes of the alternating-monophase motors in several countries.

Finally, the congress recommends that, on account of their future usefulness, exact data on the cost of electric traction be obtained.

## ELECTRICALLY-DRIVEN PUMPS AT THE CANTERBURY SEWAGE WORKS.

The new sewage-disposal works of the Canterbury Corporation have recently been opened, and a few words as to the extensive use made of electrically-driven pumps will be opportune. The contract for this part of the new works was placed with Messrs. W. H. Allen, Son, and Co., Limited, of the Queen's Engineering Works at Bedford. The complete contract includes four motor-driven sewage pumps of Messrs. Allen's Conqueror type, having suction and discharge branches each 10in. diameter, each pump being capable of delivering 100,000 gallons of sewage per hour against a head of 20ft. when running at a speed of 525 revolutions per minute and absorbing approximately 20 b.h.p. In addition to these four pumps, the firm have also installed two storm-water motor-driven centrifugal pumps, each having suction and discharge branches of 14in. diameter, and each capable of delivering 200,000 gallons of water per hour against a maximum head of 20ft. when running at a speed of 425 revolutions per minute and absorbing approximately 37 b.h.p. The centrifugal pumps are of Messrs. Allen's standard pattern, the casings being cast in two halves and bolted together along a horizontal diameter. The impellers are likewise of cast iron, and are securely keyed to a steel spindle. The bearings are of cast iron lined with white metal, and lubrication is effected by "Stauffer" spring grease cups.

The motors for driving both sewage and storm pumps are mounted on the same base-plate as the centrifugal pump in each case, and are of the company's standard four-pole shunt-wound type, designed for the speeds named when supplied with continuous current at about 450 volts. The field magnets are cast from high-permeability steel, with four poles of the same material bolted to the inner periphery on faces which are accurately bored to receive them. The pole-shoes, which are of laminated steel plates, are screwed to the pole-face, and retain in position the field coils, which can be easily removed for inspection. The armatures are of the slotted barrel-wound type, and are provided with the usual ventilating ducts. The commutators are built of hard-drawn copper bars of specially deep section, insulated with micanite sheets, and securely clamped in position. The armature shafts are mounted in standard pedestals provided with self-oiling bearings, the brush arms being carried from the outer bearing and fitted with hand worm gear for adjusting the angular position of the brushes. The pumps are provided with the usual suction foot-valves, delivery valves, charging valve, and water gauges to show the height of water in the pump when charging. Each motor is provided with a separate switch panel mounted on the wall, each panel consisting of a patent starter with no voltage and overload automatic releases, and independent shunt regulator interlocked with the starting switch in such a manner that the field resistance is all cut out at starting. Also each switch panel is pro-



The Electric Pumping Plant supplied by Messrs. W. H. Allen and Co. to the New Sewage Works at Canterbury.

vided with a suitable ammeter, a double-pole switch and two lamp brackets, the lamps being coupled across the terminals of the double-pole switch in such a manner that they are lighted only when the switch is closed. A main fuse board has also been installed, which consists of three panels of oiled slate separated by insulating fillets. These panels are provided with the necessary 'bus bars, fuses, and terminals. The illustration shows the arrangement of the four sewage pumps and motors, together with their switch panels, the arrangement being a neat one and well adapted for the purpose.

## THE COVENTRY LOG-SHEET.

In our issue for May 19 we printed an interesting lecture on the supply of cheap electrical energy for industrial purposes by Mr. J. A. Jeckell. In it reference was made to a log-sheet which Mr. Jeckell has prepared for giving a ready means of comparison between the cost of working in two successive periods. At the request of several of our readers, and with the permission of Mr. Jeckell, we reproduce herewith one of these log-sheets. They are supplied bound in book form with two such sheets facing each other, and are copyright. Each book contains sheets for 12 months, four quarters, two half-years, and one year bound up together.

## THE GLOVER SELF-LOADING CABLE-DRUM CARRIAGE.

The following two photographs show a new cable-drum carriage of unique design which has recently been made by Messrs. W. T. Glover and Co., of Trafford Park, Manchester. The object of the new carriage is to reduce the heavy labour charges frequently incurred in loading up cable drums on to the older types of carriages or on to lorries. This has often involved the sending of a number of men to a railway station where the work to be performed can

be done in a time which is small compared with the time taken by the men on the to and fro journey. With the apparatus as now illustrated the driver of the carriage is able to do all that is required himself. The operation is briefly as follows. He first backs the carriage over the drum, and then puts the usual bar through the centre of the drum, with its ends engaging in the scrolls, which form a portion of each wheel. The horse is then started forward, and the action of the wheels and scrolls revolving gradually lifts the drum until it reaches its final position in the centre of the scrolls. When this has been done, the end caps, which are seen in one of the illustrations, are added, and lock the bar in the central position. In order to unload the drum, all that is needed is to reverse the movement. This is done by backing the horse, which causes the drum axle to run in the reverse direction round the scroll work until the drum reaches the ground. The fixed scroll on either wheel is connected to the shaft portion of the carriage by means of the knife-edge wheel supports, which are shown in the illustration, and which act as the bearings. The design in the illustration shows a somewhat heavier construction than is found to be necessary after trial. The carriage in question is an interesting application of a very ancient device, and Messrs. W. T. Glover and Co. are to be congratulated on having utilised it for modern cable work. We need hardly say that they are prepared to supply these carriages to any electrical engineer requiring the same for his mainlaying department.

FIG. 1.—The Glover Self-Loading Drum Carriage.

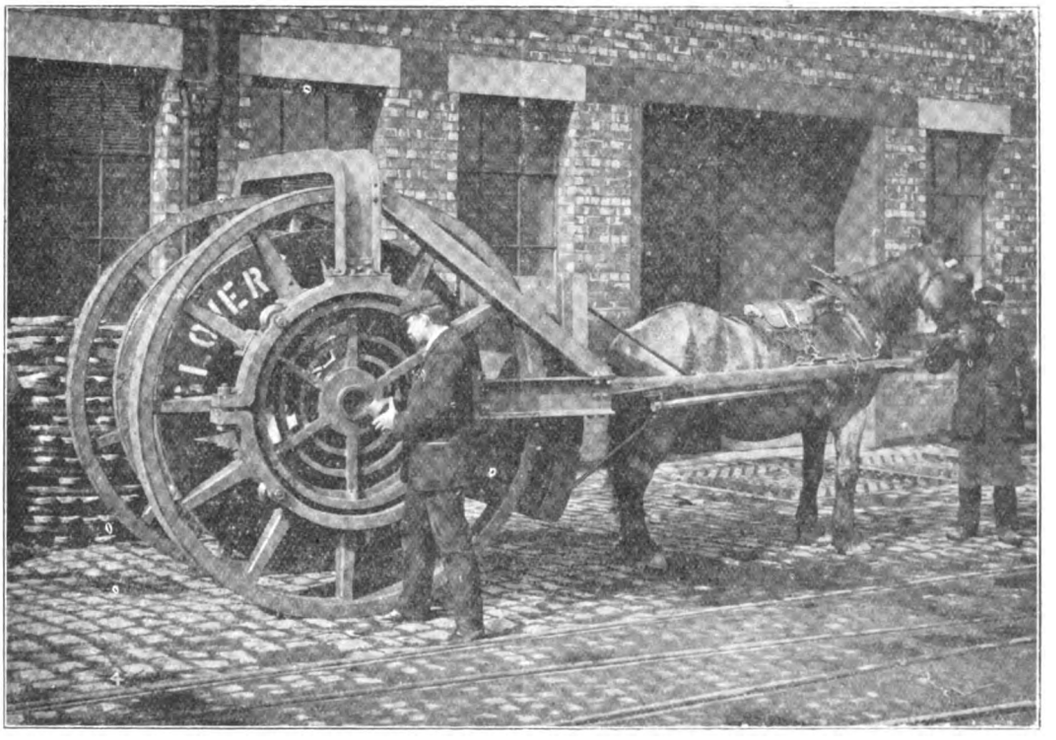

FIG. 2.—The same Carriage with Drum in Position.

**Personal.**—We are informed that Mr. J. R. Williams has been appointed power station superintendent to the Sheffield Corporation Tramways Department, but not chief mechanical engineer as well, as stated in our last issue.

## WIRELESS TELEGRAPHY MEASUREMENTS.

The communication on the above subject from Mr. W. Duddell and Mr. J. E. Taylor to the Institution of Electrical Engineers marks a great step forward in the development of wireless telegraphy. Up to the publication of this paper there had been a great deal of matter available as to different methods of etheric wave transmission, but there were hardly any quantitative data. From the paper and the further information which was given by the authors to the Institution, it is clear that the energy required both for sending and receiving messages need no longer be unknown. The preliminary tests made by the authors in Bushy Park last year were carried out for the Postal Telegraph Department at the request of the engineer-in-chief, Mr. J. Gavey, C.B. The essential feature of the investigation is the apparatus by which the very small current received can be accurately measured. Until recently there was no satisfactory instrument at the disposal of the electrical engineer for the measurement of extremely small alternating currents. This want has been met by Mr. W. Duddell by his thermo-galvanometer, which in the experiments described actually measured currents whose average values were as small as 0·0000383 of an ampere. This thermo-galvanometer is an ingenious combination of a resistance connected in series with the receiving wire of the system and a delicately suspended thermo-electric couple. The resistance is wound to form a small cup, into which one end of the thermo-junction dips. The current in the thermo-couple circuit produces a deflection which is read by means of a reflected beam of light in the usual way. The apparatus is thus of the laboratory type, and in the experiments described the receiving station was fixed, while the sending station was moved to various distances from the same. The investigations as to the connection between the value of the current received with the distance under various conditions are fully described in this paper. The sending circuit was usually arranged to give constant current, and then the resistance in the receiving circuit was varied. From the curves obtained under two conditions—*i.e.*, when the receiving circuit was tuned and when it was untuned—valuable information is obtained as to the laws governing Hertzian wave transmission. It is proved, for instance, that both these curves follow the well-established formula for determining the current flow in an alternate-current circuit. For the conditions which obtained when the experiments at Bushy Park were conducted, the formula for the current with untuned conditions became $\frac{0{\cdot}12}{\sqrt{(185)^2+(56+r)^2}}$ where $r$ equals the added resistance in the receiving circuit. When the circuit was tuned, the term $(185)^2$ vanished, and the equations of the curve became $\frac{0{\cdot}12}{56+r}$ It is interesting to note that under these conditions it would seem as though an E.M.F. of 0·12 volt was induced in the receiving aerial conductor. As is pointed out by the authors, this represents the square root of the mean square voltage over the whole time, and not over the time each set of oscillations last. To get, therefore, the actual voltage during the time the oscillations exist, one has to allow for the interval between its discharges. The authors state that it is improbable that the groups or sets of effective oscillations (taken on a basis of fifty effective cycles per train) last much more than one three-thousandth of the time interval between them. If this is so, the root of the mean square voltage induced during the oscillations cannot be much less than $0{\cdot}12 \times \sqrt{3{,}000} = 6{\cdot}6$ volts under the conditions of the very strong signals used for these tests.

Digitized by Google

This correction shows the extreme difficulty of arriving at the exact determination of the quantities involved in wireless telegraph signalling due to the intermittent oscillations of current. Further experiments were made in Bushy Park from which curves were plotted to show the connection between the value of the current received and the distance from the sending station. The distance available was comparatively small, but the general conclusion foreshadowed was that the product of the distance into the current received was constant if obstacles were eliminated. This conclusion was amply confirmed by further experiments made on the Irish Sea. In these the sending apparatus was erected on a steamer, and the receiving station was installed on shore. With the current in the sending circuit constant, Mr. Duddell proved that the product above mentioned of current received into the distance was constant up to sixty miles. The curve, however, rose in the immediate neighbourhood of the sending station, which was also the case in the Bushy Park experiments. In conclusion, congratulations are due to the authors as the successful pioneers of exact measurements of wireless telegraphy currents.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### INDUCTION MOTORS.

SIR,—Referring to "Student's" questions dealing with certain points in connection with my article on induction motors, I have pleasure in answering them as follows:

*Question I.*—R = reactance of coil C, and $c^2$ = resistance of the non-inductive resistance.

*Question II.*—As "Student" does not give sufficient data to enable the resultant currents taken by the two chokers when in series or parallel to be determined, it will be necessary to first deal with each choker separately, as it is impossible to determine the resultant currents from the information given.

"Student" states that the current and power taken by the choke coils separately on a 500-volt circuit are

4 amperes, 1,600 watts, on, say, No. 1 coil.
6 „ 2,000 „ „ 2 „

In the case of No. 1 coil $\cos\phi = \frac{1,600}{2,000} = \cdot 8$,

and $\sqrt{R^2 + p^2 L^2} = \frac{E}{C^1} = \frac{500}{4} = 125$ impedance of No. 1 coil.

For coil No. 2 we have $\cos\phi = \frac{2,000}{3,000} = \cdot 66$,

also $\sqrt{R^2 + p^2 L^2} = \frac{E}{C_2} = \frac{500}{6} = 83\cdot 3$ impedance of No. 2 coil.

With the chokers in series, the same current will flow in each. Let $e^1$ = volts across No. 1 coil, and $e_2$ = volts across No. 2 coil. Then $e^1 = C\sqrt{R_1^2 + p^2 L_1^2} = 125 \times C$, and $e_2 = C\sqrt{R_2^2 + p^2 L_2^2} = 83\cdot 3 \times C$. We now require to know the value of $\cos(\phi_2 - \phi_1)$ which represents the phase difference between $e_1$ and $e_2$. This quantity has been worked out by means of a clock diagram, and found to have a value = ·978 If E = resultant E.M.F. across both coils in series, we have

$$E^2 = e_1^2 + e_2^2 + 2 \cdot e_1 \cdot e_2 \cdot \cos(\phi_2 - \phi_1),$$

and substituting the values above

$$= (125 \cdot C)^2 + (83\cdot 3 \cdot C)^2 + 2\,(83\cdot 3 \times C)\,(125 \times C)\,(978).$$

$$\therefore E^2 = C^2 \times 42,914, \text{ and } C = \frac{E}{\sqrt{42,914}} = \frac{500}{206\,5} = 2\,4 \text{ amps.},$$

the resultant current with the two chokers in series.

With the "chokers" in parallel, the voltage between the terminals of each will be the same—*i e*, $e^1 = e^2 = 500$. If $C_1$ = current in No. 1 coil, and $C_2$ = current in No. 2 coil, we have

$$C_1 = \frac{e^1}{\sqrt{R_1^2 + p^2 L_1^2}} = \frac{500}{125} = 4 \text{ amperes};$$

also $$C_2 = \frac{e^2}{\sqrt{R_2^2 + p_2 L_2^2}} = \frac{500}{83\cdot 3} = 6 \text{ amperes.}$$

If C = resultant current when the two chokers are in parallel

$$C^2 = C_1^2 + C_2^2 + 2 \cdot C_1 \cdot C_2 \cos(\phi_2 - \phi_1),$$

and substituting known values we get

$$C^2 = 4^2 + 6^2 + 2 \cdot 4 \cdot 6 \cdot \cdot 978 = 98\,9$$

$$\therefore C = 9\cdot 9 \text{ amperes},$$

being the resultant current when the two chokers are in parallel.

So far as the rule for finding the resultant current with the series or parallel combination of two choking coils is concerned, it would follow from the working out of this example that the total impedance = the sum of the reactances and resistances respectively in each choker for the series combination, and the sum of the reciprocals of these respective quantities for the parallel combination. As regards the third question, the no-load magnetising current is found by running the motor light at its normal voltage. As the magnetic leakage, together with the magnetising current, determine the power factor, the former cannot be neglected. I must apologise for taking up so much valuable space, but the absence of anything like a fair amount (to me) of data in connection with Question II. has necessitated my trespassing on your columns to such a length.—Yours, etc, W. ROGERS.

Swansea, May 30, 1905.

### LIGHTNING.

SIR,—When writing the letter that appeared in your last issue I made a clerical error in asking what were the cases that the Lightning Research Committee excluded from Appendix A. I intended to have written "6," not "16."

Since that letter was written I challenged these figures in the course of the discussion that followed Mr. Killingworth Hedges's paper before the Society of Arts on the 24th inst., and elicited the fact that, notwithstanding the statement that the committee received reports of 40 cases of damage to "protected" buildings, the list of 34 contains *all* the cases sent in by reporters; but no explanation was forthcoming as to why seven cases of damage to "unprotected" buildings were included in a list that professed to be one of lightning conductor failures only! As regards the eighth case, there was a lightning conductor, but the damage, if caused by lightning—I have reasons for thinking it was not—occurred long before the committee were formed. Its inclusion in the list is no doubt excusable, as the committee were not informed of the whole facts.

In the course of the three years that this committee were collecting details, 27 cases of damage to (so-called) protected buildings occurred, out of which particulars of 26 were sent in. That this number was exaggerated to 40 may be a mistake or not. I cannot help saying that it may be business, but it is not science.

In his reply to my remarks at the Society of Arts, Mr. Hedges complained that I was trying to throw cold water on the committee's work, and said that if I thought the work was being done wrongly I ought to have come forward earlier and given the results of my experience. This is a reasonable charge, and as the rules of debate did not permit me to reply at the time, I shall be obliged if you will allow me to state in your columns that at first I did point out two or three cases in which the reports were at fault; but being somewhat "behind the scenes" I came to the conclusion—justified, I think, by the ultimate report—that there was a desire to throw discredit on a subject in which I am greatly interested, quite apart from business connections, and I therefore declined the request that I should examine and report to the committee on all the cases that occurred.—Yours, etc.,

May 29, 1905. ALFRED HANDS.

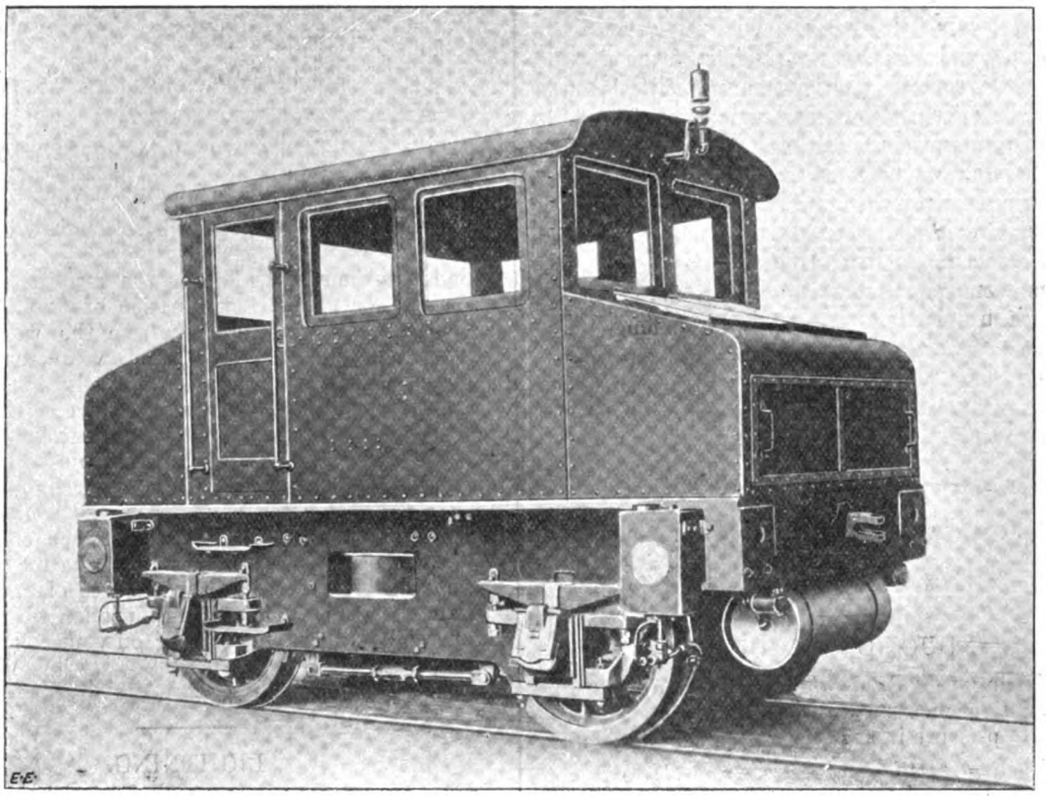
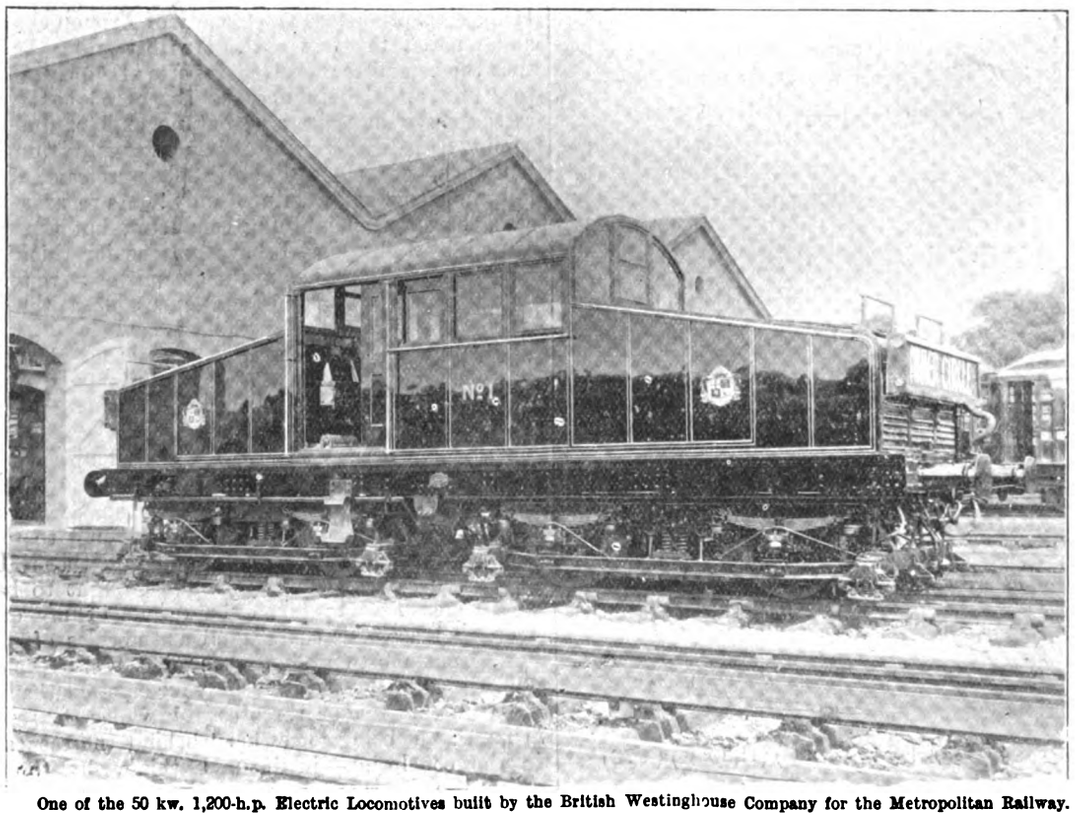
## SINGLE-PHASE ELECTRIC LOCOMOTIVE FOR SWEDISH STATE RAILWAYS.

The illustration shows a single-phase electric locomotive supplied by the British Westinghouse Electric and Manufacturing Company for the Swedish Government. One of the interesting features is the high trolley voltage for which the equipment is designed—18,000 volts—though connections are supplied for operating at several voltages lower than this, the minimum being 3,000 volts. This high voltage necessitates the use of an oil-cooled main auto-transformer and an oil-break circuit breaker, oil having insulating properties which have been amply demonstrated by service in high-tension transmission. The intention is to experiment at various line pressures with a view to ascertaining the highest working pressure suitable for the conditions prevailing upon the Swedish State Railways.

The control system is electro-pneumatic, and consists of an air-compressor driven by a single-phase alternating-current motor, an air-motor on the induction regulator, air-cylinders on the circuit breaker and reverser, and the necessary magnet valves. The air-brakes and air-sanders are also to be supplied by the above compressor. There are two connectors at each end of the locomotive, so that two locomotives can be coupled together and operated by



View of a Westinghouse 300-h.p. Single-Phase Locomotive as built for the Swedish State Railways.



One of the 50 kw. 1,200-h.p. Electric Locomotives built by the British Westinghouse Company for the Metropolitan Railway.

Digitized by Google

one motor switch. The master switch is in the middle of the cab, and is so situated that the operator has a clear view in all directions without leaving his seat. The weight of the locomotive and equipment is 25 tons, all of which is on four 41in. drive wheels. Two 150-h.p., 25-period, single-phase motors are geared, one to each axle, with a gear reduction of 18 to 70, and have shown an ability to handle a 70-ton train at 40 miles per hour without exceeding the rise of temperature for which they were designed. The equipment has been so installed on the locomotive as to permit ready access to all parts. Only the small operating devices have been placed in the cab, and the lay-out is such as to allow of the greatest convenience in operation with a maximum of safety to the operator.

The illustration shows the locomotive as sent out from the makers' works, and it should be noted that buffers and collecting device, etc., are being fitted at the railway shops in Stockholm. This locomotive has been built to the requirements of Mr. Robert Dahlander, director of the electrical department of the Swedish State Railways, who is about to carry out a most interesting series of experiments upon the application of electric power to main-line railway service.

In this connection it is to be noted that this is by no means the most powerful single-phase locomotive manufactured by the Westinghouse Company. Thus during the visit of the delegates to the International Railway Congress at the Westinghouse Works at Pittsburg on May 16 a great deal of interest was attracted to the new 1,500-h.p. Baldwin-Westinghouse single-phase alternating-current electric locomotive in use on the Westinghouse Interworks Railway. This locomotive has just been completed by the Westinghouse Company and the Baldwin Locomotive Works, and is in two parts, which, when connected together, are connected by the unit-switch system. The weight of the locomotive complete (both halves) is 135 tons, and the total length over buffers is 45ft. The maximum height with trolley down is 17ft. The driving wheels are 60in. in diameter, and the distance between centres of drivers is 6ft. 4in. The extreme width of the locomotive is 9ft. 8in. The locomotive is equipped with six single-phase, single-reduction motors, one for each axle, having a normal capacity of 225 h.p. each, with gear reduction of 95 to 18. Induction regulator control is used and a pneumatically-operated trolley. The air-brake equipment is a combination of the automatic and straight air types, and pneumatic sanders are used to sand the tracks in both directions. The locomotive is designed to operate on 6,600 volts trolley voltage, with a voltage of 140 to 320 on the motors. The locomotive has a draw-bar pull of 50,000lb. at a speed of about 10 miles per hour, and a maximum speed of approximately 25 to 30 miles per hour.

## ELECTRIC LOCOMOTIVES FOR THE UNDERGROUND.

The first of ten 50-ton electric locomotives has just been supplied to the Metropolitan Railway by the British Westinghouse Company. They will be used for hauling the main-line trains between Harrow and Baker-street, the steam locomotive that brings them up from Aylesbury, etc., being taken off at the former point and put on at the return journey. The trains used on this portion of the line are 120 tons in weight, and the new locomotives (as illustrated herewith) will propel them at a speed of 36 miles an hour. The same locomotives will be used on the Metropolitan half of the Inner Circle for goods traffic and for hauling the steam trains of other companies possessed of running powers over it. The electric locomotive will pick up the train at Edgware-road, being replaced by a steam locomotive at the point where the train leaves the Circle. The new locomotives will be equipped with four motors of 300 h.p. each, and a feature of interest is that owing to the terminus facilities being somewhat restricted it has been necessary to use motors of a smaller size than usual equipped with forced ventilation, so as to keep down the length of the locomotives to convenient limits for handling at the termini.

## INSTITUTION OF ELECTRICAL ENGINEERS.

The following extracts from the report of the Council presented at the annual general meeting, held on Friday last, May 26, shows a healthy state of progress. Since the last annual general meeting to May 25, inclusive, there have been elected 12 members, 156 associate members, 20 associates, and 273 students, making in all a total of 461 accessions. Candidates have been approved for ballot at this annual general meeting. To the class of members there have been transferred 31 associate members and 13 associates. To the class of associate members there have been transferred 57 associates and 10 students, and up to the end of December, 1904, five students had been transferred to the class of associates. The increase in membership during the past year may be seen from the following approximate tabular statement, which gives the number of members on the roll of the Institution at the end of the session 1904, and at the corresponding period in the current year:

| | 1904. | 1905. |
|---|---|---|
| Honorary members | 6 | 6 |
| Members | 955 | 990 |
| Associate members | 1 435 | 1,593 |
| Associates | 1,761 | 1,635 |
| Students | 1,107 | 1,322 |
| Foreign members | 136 | 131 |
| Total | 5,410 | 5,677 |

It has been thought desirable by the Council to pass standing orders that no candidate shall in future be elected or transferred to the class of associates who may be eligible for election or transfer to the class of members, associate members, or students Students or candidates professionally engaged as electrical engineers can, therefore, no longer join the class of associates, which, in accordance with the terms of Article 15 of the articles of association, is reserved for persons who are so associated with the application of electricity that the Council consider their admission as associate would conduce to the interests of the Institution.

After referring to honours conferred on members of the Institution during the past year, the report deplores exceptionally heavy losses by death of distinguished members. Amongst these was the late Major-General C. E. Webber, C.B., past president, honorary member, and one of the founders of this Institution.

A long list of papers read at the London meetings, and of those of the local section papers which are printed in the *Proceedings*, is given. The premiums awarded are as follows:

The Institution premium, value £25, to Mr. E. H. Rayner for his paper "On the Effect of Heat on the Electrica and Mechanical Properties of Dielectrics," and "On the Temperature Distribution in the Interior of Field Coils."

The Paris Electrical Exhibition premium, value £10, to Prof. H. S. Hele-Shaw, F.R.S., Dr. A. Hay, and P. H. Powell, for their paper, "Hydrodynamical and Electromagnetic Investigations regarding the Magnetic Flux Distribution in Toothed-Core Armatures."

The Fahie premium, value £10, to Mr. D. Murray, for his paper, "Type Setting by Telegraph."

Three extra premiums, value £10 each, one to Mr. R. Goldschmidt, for his paper, "Temperature Curves and the Rating of Electrical Machinery"; one to Mr. Miles Walker (Manchester Local Section), for his paper, "Compensated Alternate-Current Generators"; and one to Messrs. D. K. Morris and J. K. Catterson-Smith (Birmingham Local Section), for their paper on "Some Uses of the Oscillograph."

One extra premium, value £5, to Messrs. J. B. Henderson and J. S. Nicholson (Glasgow Local Section), for their paper, "Armature Reaction in Armatures."

An original communication premium, value £10, to Mr. A. B. Field, for his communication on "The Dissymmetry of a Three-Phase System."

An original communication premium, value £5, to Mr. T. Baker, for his communication, "The Magnetic Properties of Some Alloys of Iron and Silicon."

STUDENTS' PREMIUMS.

The first students' premium, value £8, to Messrs. E. A. Biedermann and J. B. Sparks, for their paper on "E.M.F. Wave Forms."

Digitized by Google

The second students' premium, value £5, to Mr. J. W. Anson, for his paper, "The Present Electrical Equipment of the London County Council Tramways."

The third students' premium, value £5, to Mr. A. C. Anderson, for his paper on "The Applications of Electricity in Mines."

An extra premium, value £4, to Mr. A. E. Jepson, for his paper on "Electric Heating."

An extra premium, value £3, to Mr. R. F. Chaffer, for his paper on "The Equipment of a Modern Generating Station, with Special Reference to the Chelsea Station of the Underground Railways."

The Council has awarded three Salomons scholarships, value £50 each, to Mr. A. E. Clayton, of King's College; Mr. E. A. F. Goodfellow, of the Central Technical College; Mr. F. C. Prentice, of University College.

Two David Hughes Scholarships, value £50 each, have also been awarded to Mr. E. A. Biedermann and Mr. J. B. Sparks, both of the Finsbury Technical College.

The American visit is referred to in the report, as is also the St. Louis Congress. As a result of a resolution of the Chamber of Government Delegates at the International Congress at St. Louis, the Institution of Civil Engineers directed the Engineering Standards Committee to consider and report on the proposal to endeavour to secure international electrical standardisation. The main committee presented their report in due course to the Institution of Civil Engineers with the request that they confer with the Institution of Electrical Engineers. The President, Mr. Alexander Siemens, has accordingly conferred with the president of the Institution of Civil Engineers, and as the outcome of the conference, a sub-committee of the Engineering Standards Committee, with the President of the Institution, Mr. A. Siemens, as chairman, has been formed for the purpose of entering into correspondence with foreign countries with a view to ascertain their attitude towards the question of international standardisation, and, if favourable to the idea, to procure their support to the proposal to form an international commission on standardisation.

The Council has been in communication with the departments of the Board of Trade and Home Office with regard to the revision of the regulations affecting the use of electricity, and they were invited during the recess by the Board of Trade to send in any observations they might wish to offer on the draft revised regulations for securing the safety of the public and for ensuring a proper and efficient supply of electrical energy. The consideration of the Council was also invited by the Home Office for the revised provisions of the Factory Act. The president-elect, Mr. Alexander Siemens, was chairman of the special committee to which the two questions were referred, and in due course the committee reported to the Council, and recommendations were made to the Board of Trade and the Home Office embodying the amendments proposed.

On the invitation of the Mining Association of Great Britain the Council in May, 1905, agreed to discuss mutually with that body the draft rules of the Home Office relating to electricity in mines. The consideration of the drafting of amendments was referred to the Traction, Light, and Power Committee, with Mr. W. H. Patchell, vice-president, as chairman, and much time and care were devoted to the work. Finally, the committee was empowered to hold a joint meeting with the Mining Association in order to exchange views, and the deliberations resulted in the inclusion of many important amendments in the recommendations of the Mining Association to the Home Office.

It is by such committees that the Institution does so much to advance the true interests of the profession. In the latter part of the report much of the other work of the Council is referred to, and we are pleased to note that the appeal for more support for the benevolent fund was most successful. Annual donations to this fund, which has already been of service in four cases, are asked for.

The financial position of the Institution continues to be a matter for congratulation by the Council. The excess of income over expenditure for 1904 amounts to £2,125. 15s. The surplus is not so large as that of the previous year, owing to certain exceptional items of expenditure.

At the annual meeting, at which the report was passed, the formal election of the new officers and Council for the next session was completed. As there were no further nominations, the gentlemen proposed by the Council take office without a ballot. The names were announced in a previous issue.

## TRADE NOTICES AND NOVELTIES.

### Electric Fans.

The new list of "Freezer" electric fans just issued by the General Electric Company, Limited, is very seasonable, being

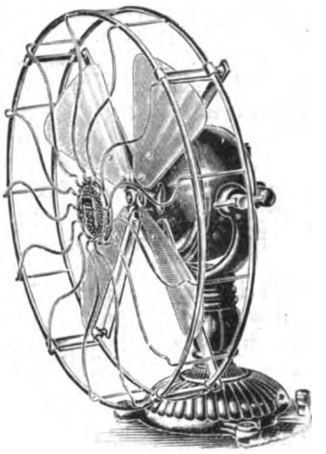


FIG. 1.

so suggestive of that refreshing breeze for which one has been longing lately. We illustrate herewith several of the patterns included. The new one (Fig. 1) is claimed to represent the most advanced ideas in the development of fan motors, com-

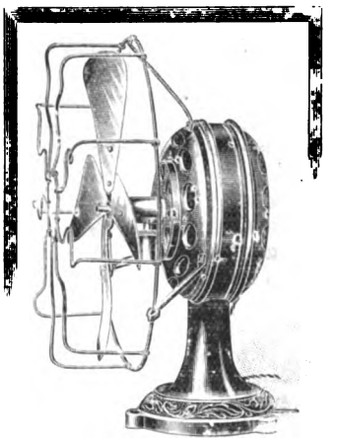

FIG. 2.

bining in one unit the three styles known as desk, trunnion, and bracket fans. It can be adjusted to propel the air in any direction without the use of special tools. The regulator with which it is provided gives three speeds. No doubt there will

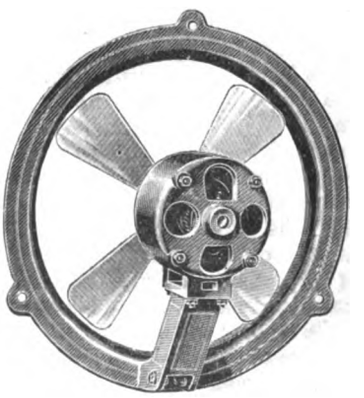

FIG. 3

be a large demand for this particular type. Fig. 2 is an example of some patterns arranged for alternating current. These are fitted with switches, but not speed regulators, their speed varying from 1,150 revolutions per minute at 40 cycles up to 1,400 revolutions per minute at 60 cycles. Something

Digitized by Google

new in the way of small ventilating or porthole fans is also listed. Fig. 3 illustrates such a fan fitted with an alternate-current motor, and specially designed for ventilating small rooms and offices. For further particulars of the above-mentioned and other useful types of "Freezor" fans we must refer the reader to the list under notice.

## Relays for Automatic Switches.

We have received a well illustrated descriptive pamphlet of relays for automatic switches in alternate-current installation from Messrs. Richardsons, Westgarth, and Co., Limited, Hartlepool, agents for Messrs. Brown, Boveri, and Co., Limited, of Baden. The action of the automatic overload relay (Fig. 1) herewith is based on Ferraris's well-known principle. A light aluminium disc is arranged to revolve between the poles of a laminated electromagnet. The electromagnet is energised by alternating current taken from the secondary side of a transformer, the secondary current being proportional to the main current of the machine. The necessary rotatory field to produce the torque on the disc is obtained in a very simple manner by adding a short-circuited copper ring to cover half the cross-section of the magnet. In this way one obtains two alternating fields differing in phase, these two fields giving a resultant rotating field, which sets up Foucault currents in and induces a torque on the aluminium disc. The spindle of the disc is horizontally pivoted, and carries a small drum on which a silk cord with a weight suspended at the end is wound up. At normal load and up to a predetermined current strength, the weight prevents the disc from turning. If the working current now exceeds the prearranged figure, the torque on the disc increases and the cord with the weight suspended at its end is wound up on the drum. When the weight rises a certain height, it closes a circuit by bringing

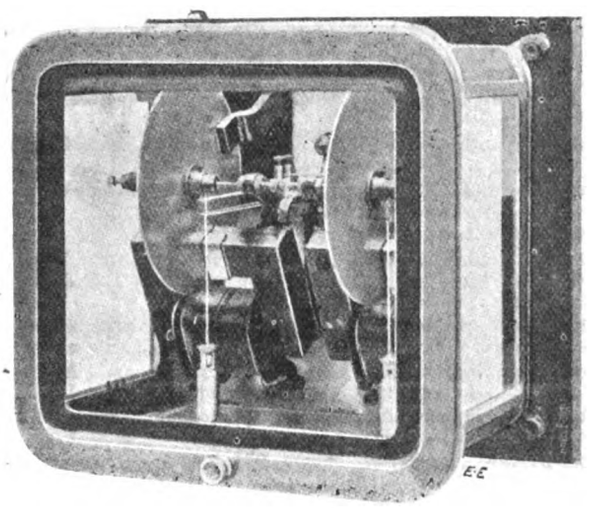

FIG. 1.—Two-Pole Overload Time-Limit Relay.

together two very light contact springs arranged in an horizontal position. A strong permanent magnet, between whose poles the aluminium disc rotates, serves to damp the action of the disc and prolongs the time taken in lifting the weight. The contact springs are connected to the circuit of the tripping solenoid arranged on the switch. When the contacts are brought together the solenoid attracts its armature, and the main switch, due to its own weight and to the action of the springs, operates. The tripping current is about two amperes, and is generally taken from the exciters, or from a small accumulator battery. Platinum, silver, or carbon is employed for the contact points.

By regulating the lengths of the cord on which the weight is suspended the time limit can be varied, and by adjusting the weight itself the current at which the time-limit device should commence to operate can be varied. The time which elapses from the moment the disc commences to rotate until the circuit for the solenoid is made depends also on the extent of the overload, so that the time is long when the overload is small and short when the overload is large. For various normal working currents the ratio of transformation of the current transformer is altered so that the secondary current is always one ampere when the pointer of the ampere-meter gives its maximum deflection, this latter being usually selected so that it is about 30 per cent. above the normal working current. Every relay is built for this current strength—*i.e.*, one ampere—and the same relay can be employed for any circuit, provided that the corresponding current transformers are made use of, no matter what the current strength in the circuit may be. The normal type of relay is single-pole, but same can be connected up to form two or three pole relays, if required. In single-phase installations a two-pole relay is generally employed; a single-pole relay is, however, sufficient. In two-phase installations two-pole and in three-phase installations two or three pole relays are used. In three-phase plants with a neutral a three-pole relay must be adopted. The tripping contacts in the multipole arrangements are connected up in parallel.

In the dispositions described above it is necessary to have continuous current for the tripping coil of the switch. Continuous current is always available in a central station, but, on the other hand, it can happen that this current is not at one's disposal, as, for instance, in a transformer sub-station, and to obtain which one prefers not to employ an accumulator battery. For such cases Brown, Boveri, and Co. have put on the market a tripping device to be operated with alternating current. This device has, we understand, met with great success. It is evident that it is not possible to actuate the tripping coil by employing a tension transformer only fed from the network, for at the very instant that the relay should operate, for instance, on a dead short-circuit, the drop in the voltage is very great or the tension disappears altogether. The tripping device must, therefore, on this account be actuated by a current transformer. In a three-phase system it can happen that the overload, or short-circuit, occurs on one phase only, and it is for this reason necessary to feed the tripping device from at least two phases of the system. As current transformers are always available for the standard type of overload time-limit relays, the former can at the same time be employed for the tripping device of winding a second coil on the core of the current transformer. This winding generally remains open, but is switched on to the tripping coil mounted on the main switch by means of the time relay as soon as the latter starts to operate, so that the mechanism of the tripping device opens the switch. In order to keep the phases separate from one another, two or three

FIG. 2.—Automatic Switch with Mechanical Relay.

separate tripping coils, mounted on the core of the tripping device, are employed in connection with a two or three pole relay respectively.

In certain cases—that is to say, when the relay is not required to operate with great accuracy, and more so when a very simple arrangement is required for tripping the switch without having to employ a separate tripping circuit—Brown, Boveri, and Co. have made use of a most successful mechanical relay, which is based on the same principle as the one just described, but is so constructed that it trips the switch directly. This relay also consists of an aluminium disc which rotates between the poles of a laminated iron core carrying a current coil, and is also with a short-circuited ring. A weight attached to the end of a lever which can be rotated is employed instead of the cord with the weight suspended at the end, and this weight is raised by the spindle of the aluminium disc operating through mechanical reduction gearing. On the weight being lifted to a certain height, it is released and falls back to its original position, striking the pawl arranged on the tripping mechanism of the switch, and enabling the switch to open. This relay is also a time relay, but the time element cannot be varied as in the case of the one previously described, in which the time element is varied by adjusting the length of the cord carrying the weight. Moreover, this relay is not so sensitive since the reduction gearing consisting of two small spur wheels has a certain amount of friction. Fig. 2 shows such a relay mounted direct on a two-pole 8,000-volt switch. The current coil is fed with low-tension current from a current transformer, which, at the same time, serves for the ammeter. This arrangement is employed in carbide works when the transformers are

Digitized by Google

subject to very heavy overloads, and the relay switches out in 30 seconds with an overload of 50 per cent., or in five seconds when the overload is 2½ times that of the normal load.

Another use to which the overload relay, when constructed as a "no-voltage" and overload relay, can be advantageously put is in connection with large alternate-current motors. Owing to a very ingenious combination, the employment of a special tripping circuit has been avoided. On the switch there are arranged as the case may be—viz., single, two, or three phase motors—one, two, or three magnet cores respectively, which are held up by means of tension coils, these latter being energised directly from the leads to the motor. As soon as the tension on these leads, owing to some reason or other, disappears, the magnet cores fall, and in dropping release a pawl and trip the switch. Now, in order to also make use of this "no-voltage" switch as an overload switch, one, two, or three pole overload time-limit relays are connected up in the motor circuit, and these relays are so arranged that, on the relay operating, a circuit is opened and not closed, as in the case of the standard apparatus—that is to say, the circuit of the "no-voltage" coil is opened so that this latter again releases the pawl of the tripping mechanism on its particular switch. If the corresponding driving gear of the switch is now combined with that of the starter of its corresponding motors, so that the switch after it has been switched out can no longer be switched in till the lever of the starter has been brought back to its original position, one obtains a switching arrangement such that the motor is fully protected against an overload which would be too large, or against a wrong manipulation, or also to allow it to remain switched in when the tension disappears.

Further particulars of these interesting devices will be found in the pamphlet under notice; also a description of a reverse-current relay. Several useful diagrams are included.

## FORTHCOMING EVENTS.

FRIDAY, JUNE 2.

**Optical Convention.**—Continued at the Northampton Institute till to-morrow.

SATURDAY, JUNE 3.

**Association of Municipal and County Engineers.**—Meeting at Gloucester.

MONDAY, JUNE 5.

**Society of Engineers.**—"Improvement of London Traffic."

THURSDAY, JUNE 8.

**Royal Institution.**—At 5 p.m., "Electromagnetic Waves," by Prof. J. A. Fleming (Tyndall Lecture III).

**Physical Society.**—June 16, "The Ratio between the Mean Spherical and Mean Horizontal Candle-power of Incandescent Lamps," by Dr. J. A. Fleming; "The Electrical Conductivity of Flames," by Dr. H. A. Wilson; "Contact with Dielectrics," by Mr. R. Appleyard; "The Pendulum Accelerometer, an Instrument for the Direct Measurement and Recording of Acceleration," by Mr. F. Lanchester; "A New Form of Pyrometer," by Mr. N. V. Stanford; and an exhibition of a refractometer by Mr. R. Appleyard.

**Electrical Contractors' Association.**—Dinner at the Holborn Restaurant, June 27.

**Incorporated Municipal Electrical Association.**—June 27-30, annual convention.

## PHYSICAL SOCIETY.

At the meeting of this society on May 12, Dr. C. Chree, F.R.S., vice-president, in the chair, Dr. A. D. DENNING described a simple method of determining the radiation constant, suitable for a laboratory experiment. The apparatus consists of a hemispherical copper cap to the outside of which is affixed a jacket through which steam or water can be passed. The receiving surface consists of a silver plate, and the rate of rise of temperature of the plate is measured by means of a silver-constantan thermo-junction. When performing the experiment, a non-conducting pad is placed between the hemisphere and the silver disc till the temperature of the jacket is uniform. Then the pad is slid out, and the deflections of the galvanometer in the thermo-junction circuit are noted every few seconds. By plotting these deflections on a curve, the initial slop of the curve—*i.e.*, the initial rate of temperature of the silver disc—is obtained; and from this, knowing the constants of the disc, etc., the radiation constant can be calculated. The author gives some numbers which indicate that a very fair degree of accuracy can be obtained.

Prof. CALLENDAR asked what steps had been taken to protect the area of the edges of the silver disc, which appeared to be about half the area of the upper surface, from the oblique radiation of the hemisphere. The upper surface alone was taken as the effective area in the calculation. He had found this difficulty in applying the Crova disc method to the measurement of radiation in a previous case, although the radiation was nearly parallel and normal to the disc, instead of being distributed over a hemisphere. He thought that greater sensitiveness would be obtained by using a single short constantan wire for the couple. It was necessary that this wire should be exceedingly fine to prevent error in the temperature measurement owing to cooling of the end near the junction by conduction. A copper disc appeared preferable to a silver disc as reducing the number of junctions of different metals. The constantan wires used by the author did not appear to be fine enough to eliminate this source of error, which, however, would tend to compensate the error introduced by the neglect of the area of the exposed edges of the disc.

Mr. CAMPBELL asked whether the convection currents do not introduce considerable error. The effect of the rim of the disc could be made of relatively less importance by increasing the diameter of the disc.

The AUTHOR, in reply, said that from the form of the radiator the amount of radiation received by the edges of the disc was only a very small fraction of that received by the horizontal surface, whilst the method of placing the radiator over the disc would probably not cause any great changes in the condition of the air directly under the radiator.

Another paper by Prof. H. L. Callendar on "A Bolometer for the Absolute Measurement of Radiation" is unavoidably held over.

## APPOINTMENTS VACANT.

**General Manager,** Johannesburg, £2,000; Station Engineer, £1,000, with house. Applications to Mordey and Dawbarn, 82, Victoria-street, Westminster.

**Chief Assistant Electrical Engineer,** Battersea Borough Council. Commencing salary, £200 per annum. Applications by noon on June 6.

**Assistant Borough Electrical Engineer,** Poplar. Salary, £200 per annum, rising by annual increments of £10 to a maximum of £300 per annum. Applications by June 14. See advertisement in last issue.

**Articled Improver,** Maidenhead Electricity Works. Applications before June 9. See advertisement in last issue.

**Junior Engineer,** Dundee Electricity Department. Applications to H. Richardson, A.M.I.E.E., general manager and engineer. See advertisement in last issue.

**Jointer,** experience with electric light cables, East Sussex County Asylum, Hellingly. See advertisement in last issue.

**Director,** with £5-10,000, large electrical supply company on the Riviera. See advertisement in last issue.

**Partnerships (two).** See advertisements in last issue.

**Assistant Engineer,** Newcastle City Asylum, Gosforth. Wages, 36s. weekly and house on the estate. Applications by June 3. See advertisement in last issue.

**Switchboard Attendants (three),** North of England. Wages to commence 35s. per week of 56 hours. See advertisement in last issue.

**Draughtsman,** Trowbridge. Salary, £100 per annum. Applications to Mr. R. W. Merriman, County Offices, Trowbridge, by June 10.

**Electrical Engineer's Assistant,** Bray, Ireland. Salary, £60 per year. Applications by June 5.

**Fitter-Driver,** Clesthorpes. Wages, £2 per week. See advertisement.

## A NEW AUTOMATIC POINT SHIFTER.*

BY J. P. TIERNEY, STUDENT.

The point shifter which I am about to describe is that which is used on the Dublin United Tramways system. It is the outcome of experiment in connection with a previous point shifter which was discarded in favour of the present one on a point of cheapness in first cost, maintenance, and more efficiency in working. The first arrangement just mentioned necessitated a magnet being placed on each car, which, when energised, operated a switch box in the street, the lid of which being non-magnetic had no influence on the magnet of the car, but beneath the lid was hinged a soft-iron plate which was lifted upwards against the lid of the box by the magnet on the car, the lifting of the iron plate closing the circuit from the overhead line to the electromagnet which operated the point tongue.

This apparatus was installed at the London Bridge-road junction of the Sandymount line on May 23, 1903, and worked satisfactorily until Aug. 29 of the same year, when the present point shifter was installed in its place; the present point shifter, as will be seen, only requiring a contact on the trolley globe of the car as against an electromagnet in the former arrangement. It may be of interest here to note that the electromagnet on the car gave a pull of 2lb. at an air-gap of 2in., the pole-pieces being elongated and fitted with shoes so that the period of time during which the magnet exerted its influence on the switch box was extended as much as possible.

The point shifter at present in use can be applied to any existing system of points in either of two different methods. The first method consists in having each point always set for one particular line; the cars on this particular line will thus not have to move the point, but the cars going on the other line

* Paper read before the Dublin Section of the Institution of Electrical Engineers, May 11, 1905.

Digitized by Google

will always move the point for themselves and set it back again after they have gone through. The second method is one in which the points will not be fixed for any particular line, but each car approaching it will move the point for itself irrespective of whatever route it desires to go should the point be set against it. In this case the cars need not throw back the point to its original position. It is equally applicable to all systems of electric traction. whether operated on the trolley, conduit, surface-contact, or accumulator systems.

I will now describe the first method of operation, which I will do under four different headings—first, the point or street equipment; secondly, the car equipment; thirdly, the overhead line equipment; and fourthly, the general method of operation. The street equipment of a point with the apparatus is identical for either methods of operation. It consists of two cast-iron boxes mounted one on either side of the point, each containing a special design of stopped solenoid. The plungers of these

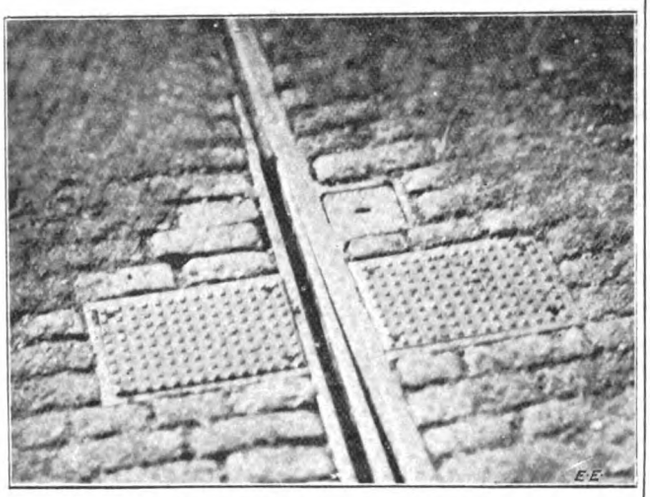

FIG. 1.—Automatic Point Shifter at Dublin.

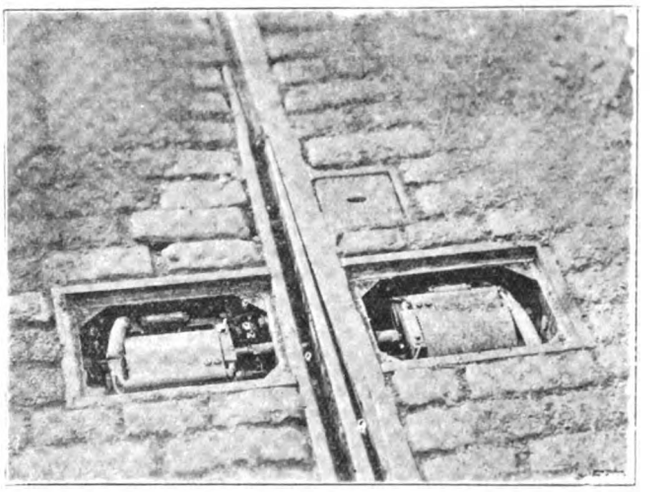

FIG. 2.—Automatic Electric Point Shifter.

solenoids operate on a special forging which, when pushed one way or another, operates the point as desired. These cast-iron boxes measure 14in. by 12in., and are 9in. deep, and constitute the only alteration in the permanent way. The solenoids used are of the stopped type, but instead of the plungers pulling their work after them when sucked into the coil, as is the general practice, the stop of the solenoid is bored out and a brass rod screwed into the plunger passes through the top. By this means the solenoid plungers are used to push instead of to pull their work. This arrangement has the advantage that the plunger rod pushing against the rod which passes through the point acts as one buffer of a railway car to another, and need not necessarily be in line with one another, which would be required if both were screwed or otherwise securely fastened together.

The mechanical details of the point equipment consist of a rod which passes through the casting of the point beneath the floor of the switch; on both ends of this rod are securely fastened two castings, each of which carry a pin $\frac{5}{8}$in. diameter. One of these pins passes through the running head of the point casting and one through the check rail. The point tongue lies between those two pins, but it is not bored or altered in any way. The tongue of the point lying between these two pins cause the movement of the pins to control the movement of the point. The advantage of this arrangement lies in the fact that the tongue of a point can be replaced at any time without disconnecting or interfering in any way with the gear of the point shifter. From this it will be seen that the solenoid plungers moving the rod which passes beneath the floor of the point also move the point tongue. By this arrangement, to remove a solenoid it is only necessary to disconnect the wire coming from the line contacts and lift the solenoid out, the solenoids only sitting at the bottom of the street box, and not being mechanically secured to same, the other end of the solenoid coil being permanently grounded on the magnet case. The solenoid coils are enclosed in a hermetically-sealed zinc case, this in turn is placed in a cast-iron cup-shaped covering, the stop of the solenoid and this cup-shaped covering being in the one piece. This cast-iron covering completely encloses all parts of the solenoid, the plunger rod working through a gland in the cover. This ensures the solenoid being absolutely waterproof, which is a necessity, as they must frequently work under water during periods of very heavy rain. The solenoid coils are wound to operate on the 500-volt line pressure direct without any resistance.

The car equipment consists of a contact piece mounted on the trolley globe of the car (Fig. 4). This contact piece is insulated from the globe, and is connected by a wire brought down the trolley pole of the car to a switch on the driver's platform; the driver, by operating this switch, can make this contact piece electrically alive. The driver's switch can only be operated by a special handle, which can only be removed when the switch is brought to the "off" position. This prevents the switch on the rear end of a car being interfered with by passengers, and also ensures that the switch on the rear end is left in the off position, each driver only being supplied with one handle.

The overhead line equipment consists of an ordinary ear with two hubs (Fig. 5) soldered in the usual manner on to the trolley wire. Each of these hubs carry a special insulator, which in turn carry between them a contact strip. This strip is so suspended and placed that when the trolley head of the car is passing under the ear, the contact piece on the trolley head will rub against and make contact with this contact strip on the line. This contact strip is connected to one of the solenoids in the street boxes through a suitable switch and fuse placed in a box on the nearest street pole. The car carrying this contact strip is placed about 48ft. distant from the point, so that the front of the car is 20ft. from the point when same is operated. This gives the driver full opportunity of seeing that the point has been properly operated before he goes through. A second contact strip is placed on the trolley wire in an exactly similar manner to the first which I have just described. This is placed directly over the point, so that when the wheels of the car have cleared the point a few feet the trolley of the car will pass through this second contact. This contact is electrically connected to the second solenoid of the point in a similar way as the first contact strip was connected to the first solenoid. When the driver of a car approaches a point which it is necessary to move, he closes the switch on his platform, thereby making the contact piece on the trolley head of his car electrically alive. When the trolley of the car passes under the first contact strip on the overhead line, the contact piece on the trolley head rubbing against the contact strip on the line makes same electrically alive, thereby sending a current to one of the solenoids at the point, which solenoid on becoming energised will shift the point to the desired position. When the trolley of the car has passed from under the first contact strip, the current is cut off this solenoid. The car having passed through the point the

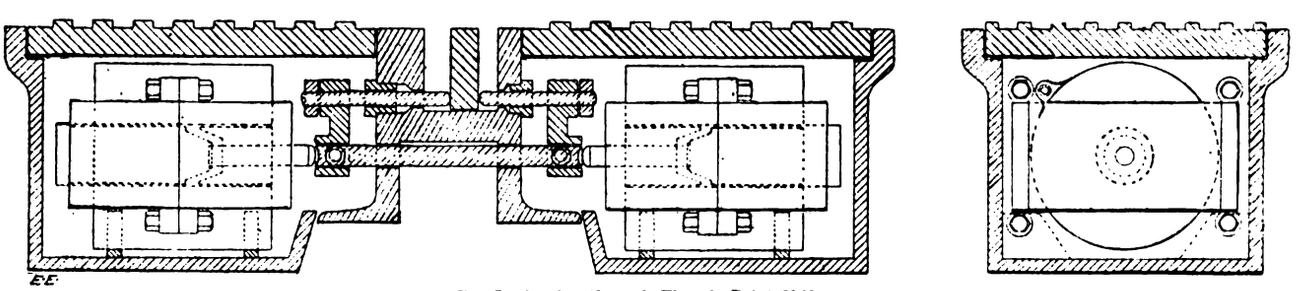

FIG. 3.—Section through Electric Point Shifter.

Digitized by Google

trolley passes under the second contact, which is now made electrically alive, thereby sending the current to the second solenoid, which throws back the point to its original position. If the driver of the car does not want to move the point, he leaves the switch in the off position.

On the Dublin United Tramways the car equipment has been reduced to the placing of a non-insulated contact piece on the trolley globe of the car. By fitting the cars of certain routes

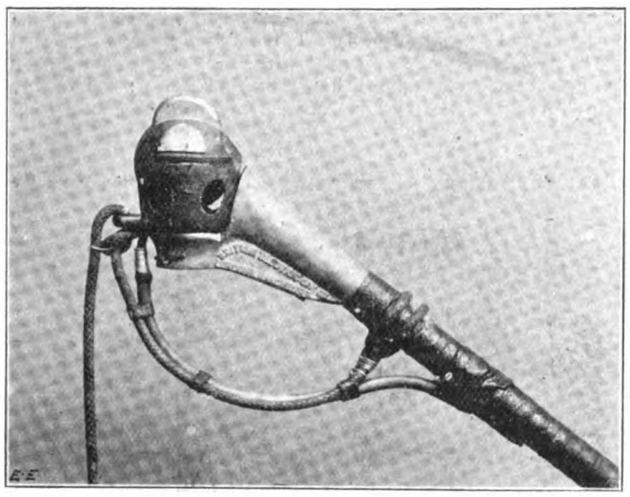

FIG. 4.—Trolley Head with Special Contact Piece.

in this manner the satisfactory operation of the points has been accomplished. To briefly explain how this has been done, I will take a specific example with which you are all doubtlessly acquainted. The points at the bottom or Nassau-street end of Dawson-street and the top or Stephen's-green end of Dawson-street are electrically operated. The contact strips for operating the point at the Nassau-street end are placed on the right-hand side of the line in the direction of travel. The Terenure,

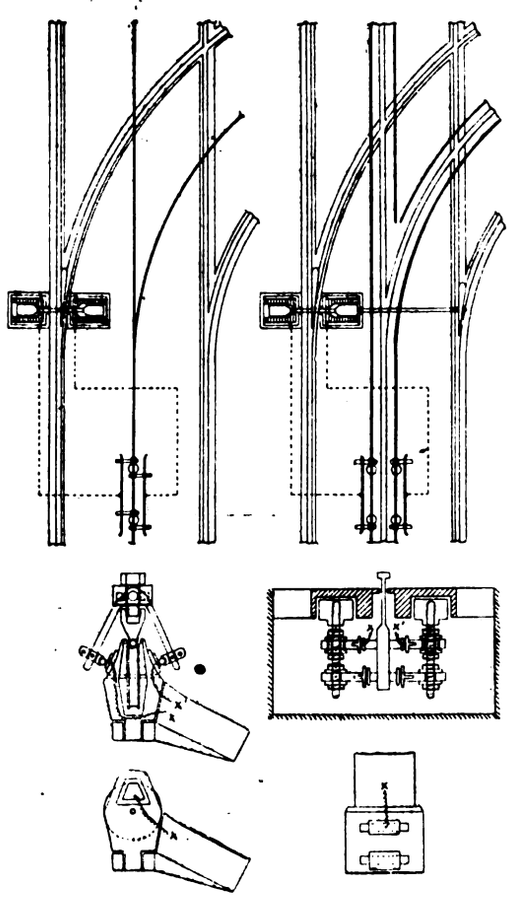

FIG. 5.—Details of Point-Shifting Contacts as applied to both Trolley and Conduit Systems of Traction.

Dartry, and Clonskea cars are fitted with contacts on the right-hand side of the trolley globe, so that they open this point for themselves and close it after they have gone through, leaving the point set right for the Dalkey and Donnybrook cars. The contact strip for operating the point at the top of Dawson-street is placed on the left-hand side of the line, the Clonskea cars being fitted with contacts on the left as well as on the right-hand side of the trolley globe, so that they open this point for themselves and close it after they have gone through, leaving the point set right for the Terenure and Dartry cars. Although at first sight the use of this arrangement of car equipment may appear limited, but having gone into the working of the routes of the Dublin tramways, which is one of the largest networks in the United Kingdom, I find that the arrangement can be practically used throughout the system.

In the second method of operation, in which this point shifter can be fitted to a point, the street equipment is identically similar to the first method which I have just described, so I will pass to the overhead line and car equipment, where the difference exists. The overhead line equipment consists of a double-hubbed ear carrying the two insulated hangers, which, as before, is mounted on the overhead line about 48ft. from the point. In this case the two insulated hangers carry two contact strips one on either side of the line, each of which are insulated from the line and from one another, and each one is connected to one of the solenoids as in the first method. In this case there are no contacts over or after the point, as each car having perfect control for either route, it is not necessary for the cars to throw back the point after they have gone through. The car equipment in this method consists in having an insulated contact piece on each side of the trolley globe; each of these contact pieces is connected to a two-way switch on the driver's platform whereby he can make either of these contact pieces electrically alive, but he is unable to make the two contact

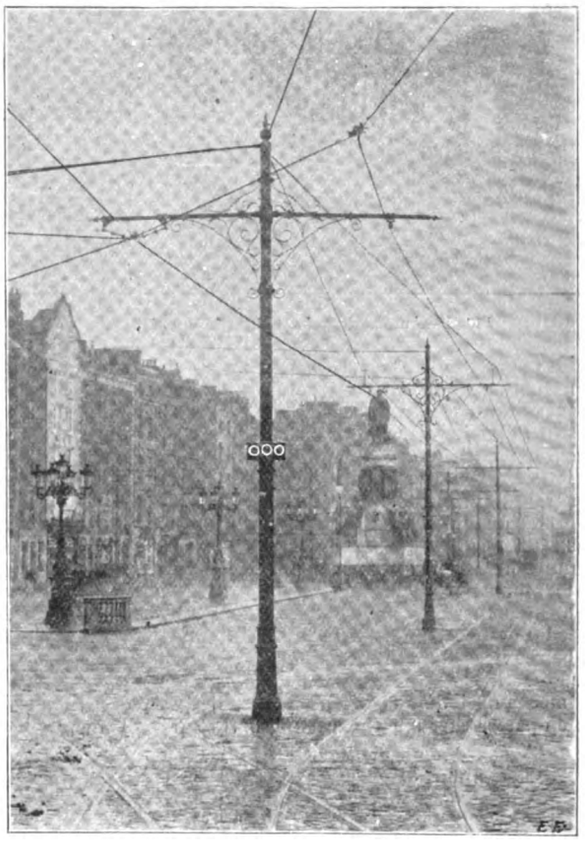

FIG. 6.—Signal Lamps to show position of Points.

pieces alive together; otherwise the details of the switch are identical with that described in the first method of operation. When the driver of the car approaches a point which it is necessary to move, he turns his switch handle on platform to the right or left, according as he desires to go on the right or left track. If he puts it to the right, he makes electrically alive the insulated contact piece on the right-hand side of the trolley globe of the car. When the trolley of the car passes under the contact strips on the overhead line, it makes electrically alive the contact strip on the right-hand side of the line, which is connected to the solenoid in one of the street boxes at the point which, when energised, moves the point for the right-hand road. If the driver desires to go to the left, he puts his switch on the platform to the left, and the operation is the same as in the former case, except the other solenoid now gets the current, thereby moving point for the left-hand road. It will, therefore, be seen that the putting of the driver's switch to the right or to the left controls which solenoid in the street boxes at the point becomes energised, and, therefore, controls for which line the point will be moved.

At night-time motormen of cars experience difficulty in seeing if their points are properly set. To obviate this difficulty, signal lights are placed on some pole convenient to the point, these lights indicating the exact position of the tongue of the point, whether being set for the right or left hand point, or if it is jammed in a midway or neutral position. The signal arrange-

Digitized by Google

ment consists of three lights placed horizontally in a row (Fig. 6), the centre one being green and the two outside ones red. If the point is set for the right-hand route, the left-hand red light and the green light are lighting. This shows a green light or "all clear" signal for the right-hand route, and a red light or "danger" signal for the left-hand route, indicating that the point is set in the proper position for the right-hand route. If the point is set for the left-hand route, the right-hand red light and the green light are lighting, which shows a green light or "all clear" signal for the left-hand route and a red light or "danger" signal for the right-hand route, showing the point to be set for the left-hand route. These lights are controlled by a switch in one of the boxes containing the solenoids at the point, and is operated by the tongue of the point itself, consequently they are *entirely* and solely controlled by the point. This switch is so set that should the tongue of the point accidentally get jammed midway in a neutral position, all lights will go out, which will indicate the state of affairs to the motorman.

# LEGAL INTELLIGENCE.

## BIRMINGHAM CORPORATION V. BIRMINGHAM CANAL COMPANY.

Mr. Justice Farwell last week delivered his reserved judgment in this case, of which we have already given a report.

His Lordship said that the question turned on the true construction of Section 82 of William IV. of 1834. The plaintiffs contended that their generating station was a manufactory within the meaning of the section. The defendants contended that the only manufactories entitled to the benefit of the Act were manufactories belonging to persons who at the date of the Act possessed steam-engines used for the purposes of such manufactories, or, in other words, that additional steam-engines were allowed to manufactories then using steam-engines and nothing more, and that if even this was not so a generating station was not a manufactory within the meaning of this particular Act. *Prima facie* the words "the above manufactures" must mean the manufactures mentioned above, and that only the manufactories so mentioned were those having steam-engines in existence at the date of the Act. It was said that the reference to the future acquisition of land and the future extension of the canals excluded this view, but it had to be observed that it was the future erection of the manufactories which was mentiond as contemplated, and it was quite possible that engines might be erected after the Act on land thereafter acquired within 200 yards of canals thereafter cut and yet be for the use of manufactories existing at the date of the Act. Further, the Act distinguished in the face of it between manufactories and cornmills, and collieries, ironworks, and other works. The manufactories were qualified by the use of the word "above." Cornmills had no such qualification, and collieries, ironworks, and other works had no claim to draw water for any new fire-engines at all. The section undoubtedly contemplated the existing state of things, and that only in reference to collieries, ironworks, and other works, and there was therefore no apparent reason why the existing state of things should not be equally intended with respect to manufactures. The inference he drew was that steam-engines had been erected and were in use for some manufactories and cornmills under an Act of George III., and also for some ironworks, and without any statutory authority, and that the *status quo* was preserved as to all these with additional rights in the case of existing manufactories to erect and use further and other engines for such manufactories on the existing canals and also on canals thereafter to be made, while all cornmills within the limits had the right whether erected before or after the Act. He saw nothing unreasonable in this construction, but even if he did this apparent unreasonableness would not justify him in striking out the "above" or altering the plain words of the section. Even if he could read "above manufactories" as equivalent to "any manufactories similar to those mentioned above" he did not think that a generating station could fairly be deemed to be included therein. The result was that the plaintiffs' claim failed.

Judgment for defendants, with costs.

## BOGOTA TELEPHONE COMPANY.

Mr. Justice Swinfen Eady, in the Chancery Division on Saturday, had before him a petition presented by the Bogota Telephone Company, Limited, for the sanction of the Court to an alteration of its memorandum, by giving the company power to issue debentures.

His Lordship remarked that the memorandum was in peculiar form, and the company was, perhaps, justified in desiring to make the alteration. He would, therefore, sanction the addition to the memorandum, as asked.

## AN ELECTRICAL ENGINEER'S CLAIM.

In the King's Bench Division last week Mr. Justice Wills had before him the case of Pressland *v.* Edmundson's Electricity Corporation, Limited, in which the plaintiff, an electrical engineer, claimed commission or remuneration for professional services in connection with the establishment of electric supply stations in the neighbourhood of Wigan. Defendants denied liability, or, alternatively, if they were held liable, brought a sum of money into court as sufficient to meet the claim.

In October, 1903, defendants, to whom the scheme had been introduced by the plaintiff, entered into a contract for carrying out the works for £300,000, and on an agreement, dated Aug. 6, 1897, plaintiff claimed 5 per cent. commission, £15,000, or, alternatively, reasonable remuneration for his services. For the defence it was denied that plaintiff introduced or promoted the scheme or that they requested him to do any work; or, if plaintiff did any work, it was under another agreement, by which defendants, in partnership with two other companies, were to pay plaintiff out-of-pocket expenses, and when the Bill to carry out the scheme became an Act he was to receive such further remuneration as the partnership might consider reasonable.

Plaintiff, in his evidence, described the work he did in connection with the promotion of local Bills for electric power, and said he was continually travelling about seeing public authorities, and making arrangement for provisional orders. There were no less than 122 local authorities, and 18 000 factories and a number of quarries in the area were supplied with electric power. In cross-examination, plaintiff said in the course of five years he had received £20,000 from defendants, but had spent a third of that sum in travelling and hotel expenses.

Mr. C. A. Russell, K.C., said the defendants went into the matter apart altogether from Mr. Pressland, who had never done any work on the scheme. The partnership syndicate had spent £19,200 on the promotion of the Bill, and up to the present they had not received any sort of profit at all. All plaintiff had done was to canvass local authorities.

His Lordship, in giving judgment, said he had come to the conclusion that the work done by the plaintiff did not come within the agreement of 1897, but he thought, having regard to all circumstances, that a jury would have awarded him £1,200.

Mr. Wallace informed his Lordship that £1,100 had been paid into court.

Judgment was entered for plaintiff for £1,200, with costs.

## WORKMEN'S COMPENSATION ACT.

### Stevens v. Leicester Corporation.

At the Leicester County Court last week Judge Wightman Wood heard an action brought by David Stevens against the Corporation under the Workmen's Compensation Act. The plaintiff was employed by the Corporation in the construction of the electric tramways in Leicester. On Aug. 28, 1903, he met with an accident. It appeared that he was engaged in the operation of shooting cement, and that a gust of wind blew some of the cement into his eyes. He suffered great pain at the time, and there was no doubt that he sustained serious injury. Stevens struggled on with his work for a few hours that day and the next morning tried to continue, but he suffered such acute pain that he was sent by his foreman to the infirmary. He was there examined and the doctors came to the conclusion that he had been so seriously injured that he could not work. They gave him a certificate to that effect. He took the certificate and his infirmary book, which contained a written notice of the accident, to the head foreman. Stevens was put on half-pay for 17 weeks, after which the Corporation gave him light employment, paying his original rate of wages. The Corporation sent him to an eye specialist at Nottingham, and in consequence he had to discontinue his light work, the Corporation discontinuing the former half-pay allowance on the ground that it was voluntary.

Confirmatory evidence having been given on behalf of the plaintiff, the Town Clerk, on behalf of the defendants, said there had been an arrangement in force in all the departments of the Corporation for many years that if a man met with an accident and was incapacitated from work he was put on half-pay. This pay went on during a workman's incapacity, but the case was revised from time to time for obvious reasons.

The Judge said this was a very clear case. The plaintiff was engaged in employment definitely protected by the Workmen's Compensation Act. By force of that Act plaintiff became entitled to compensation—of half the wages he was earning. If the position taken up by the Corporation was a correct one, it would set up a local law which would be over-riding the general law brought into force for the protection of workmen, under which workmen were not allowed to contract themselves out.

Judgment for plaintiff.

## PRODUCTION OF TRAMWAY TICKETS.

At Bradford Police-court, John Wilkinson was summoned for failing to show his ticket on an electric car when requested to do so.

It was stated that when the inspector went round to examine the tickets the defendant said that his was on the floor. He did not show it, and refused to pay the fare.

The Stipendiary drew attention to a Sheffield appeal in a similar case. A passenger pointed to his ticket on the floor, but refused to pick it up to show it. The case was taken to the High Court, and the decision was against the Corporation, as the Court held that the man was not bound to handle the ticket.

The case was adjourned for a week in order that the prosecution might consider the point raised.

# COMPANIES' MEETINGS AND REPORTS

## REUTER'S TELEGRAM.

The annual meeting of this Company was held on Wednesday, Admiral Sir J. C. Dalrymple Hay presiding.

The Chairman stated that great expense had been incurred in reporting the Far East campaign. Latterly, at any rate, this heavy

Digitized by Google

expenditure had not been covered by the receipts; indeed, during one month, at least, a not inconsiderable loss was incurred. This was due to the fact that little or no news was being received while expenses were going on all the time. The other branches of the Company's activity, which the Board had carefully fostered, made up for the deficiency, and indifferent results in one department were counterbalanced by profitable business in another. The Board's chief preoccupation during the past 12 months had been the service from Russia, where the collection of news had become a reality owing to the abolition of the censorship, which had existed from time immemorial. In order to be able to do full justice to the new state of things the directors lost no time in strengthening the staff in that country, and the Company were now in a position to furnish their supporters with detailed and accurate accounts of the important events transpiring in the Russian Empire. They were taking advantage of the establishment of direct telegraph communication with Abyssinia to extend their organisation to that country. The Company's operations in South Africa have been placed on a satisfactory footing.

## WEST INDIA AND PANAMA TELEGRAPH.

The fifty-sixth ordinary general meeting of the shareholders of this Company was held last week at Winchester House. Particulars of the report appeared in our last week's issue.

Mr. W. B. KINGSFORD, who presided, stated that the traffic receipts for the current half-year showed considerable increase at the time when the report was issued. Since then a return had been received stating that the estimated receipts showed a marked improvement. The traffic receipts at the British West India station had remained stationary, and this was disappointing, because they had reason to anticipate that there would certainly be some increase, owing to the failure of the Continental beetroot crop and the higher prices obtained for West Indian sugar, and also to the reported improvement generally in the commercial prospects of the colony. During the early part of last year they were in communication with the Government with reference to an extended cable system in the West Indies, and certain proposals were made by them which involved, if carried out, the grant of an Imperial subsidy. They had all read of the new national defence scheme for the Empire, and of the announcement that the Government had decided to withdraw white troops from the West Indies, and also to reduce the naval forces in those waters, and to discontinue the maintenance of St. Lucia as a coaling station. The Colonial Office had recently informed them that the proposals made by the Company could not be entertained.

In reply to a question, the CHAIRMAN stated that the directors were carefully watching wireless telegraphic developments in the West Indies.

The report was unanimously adopted.

## WORCESTER ELECTRIC TRACTION.

The second ordinary general meeting of this Company was held at Donington House, Mr. H. S. Day (chairman of the Company), presiding.

The CHAIRMAN, reviewing the position generally, remarked that the major portion of the line was opened on Feb. 6; the London-road was opened in April, and the six furlongs in the Bath-road in June. The amount of revenue from the cars was £11,640, and the amount of expenditure £6,308, giving a profit of £5 332. With the 'buses the revenue was £3,970, the expenditure £4,134, and the net revenue loss £164. The Board of Trade have extended the time for the completion of the whole of the remaining lines until Dec. 17, 1906. There was some likelihood of the proposed St. John's route extension being revived in the future. The Bath-road section had not yet realised expectations.

The report was unanimously adopted, as were the following resolution: "That the following resolution, which was passed at an extraordinary general meeting held on Dec. 17, 1902, be rescinded: 'That the capital of the Company be divided into 12,000 shares of £5 each to be called ordinary shares, and 12,000 shares of £5 each to be called preference shares, and to confer on the holders thereof the right to a fixed cumulative preferential dividend at the rate of 6 per cent. per annum on the capital for the time being paid up on such shares, and such preference shares to rank as regards dividend in priority to the other shares, and not to confer any further right to participate in profits or surplus assets.'"

## CALLENDER'S CABLE AND CONSTRUCTION.

The ninth general meeting of this Company was held last week at Hamilton House, Victoria-embankment. Particulars of the report appeared in our issue of the 26th ult.

Mr. HENRY DRAKE, who presided, stated that during the year the Company had had a considerable amount of trouble to do business. In no year since the inauguration of the undertaking had it been more difficult to obtain orders or to get them at satisfactory prices. The work was largely with municipalities, and the financial stringency, together with the new views which were taken about municipal trading, had had a considerable influence on the amount of work carried out by the local authorities. It had therefore been difficult for them to borrow money as freely as they had been in the habit of doing, and even the most necessary extensions in many cases had to stand over until better times. With the advent of improved financial conditions, orders which had been under consideration for many months were being given out. The business of the Company had never been in a healthier condition than it was at present. The Board had no uneasiness as to the future. They objected to the prices which the Company were getting for their work, but they recognised the existing condition of affairs, which they believed would shortly pass away. They had been especially busy in the East, which they had made their own field, and in which they hoped to maintain their ascendancy. They had made several endeavours to open up trade with Continental countries, but tariff difficulties stood in the way, preventing them from submitting tenders which could be of the slightest use. The Company were getting considerable trade in the important business of power distribution. The fact that they had been in the business from the beginning and had pioneered the work had given them a very strong position in the field, and one which they would do their utmost to retain. Their policy in acquiring the undertaking of the Anchor Company had been amply justified.

The report was adopted.

## NEW COMPANIES REGISTERED.

**"Otto" Electrical Manufacturing Company (1905), Limited.**—Capital, £75,000. Object: to acquire the business of the "Otto" Electrical Manufacturing Company, Limited, to adopt an agreement with A. C. M. Jenkins and Co., and to carry on the business of electricians, suppliers of electricity, etc.

### Liens Registered.

**Blackpool, St. Annes, and Lytham Tramways Company, Limited.**—Lien registered May 22, for £5,000 5 per cent. debentures, part of £15,000; amount previously issued, £10,000; no trustees; charged on the undertaking and all the property, present and future, including the uncalled capital.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Palermo.**—The Sicilian Railway Company require tenders for electric wires and cables. Tenders by June 11.

**Darlington.**—The Corporation invite tenders for switchboard extension and booster. Tenders by June 19.

**Cataqueses (Spain).** — The local light and power company require tenders for electrical plant. Tenders by July 1.

**Grays Thurrock.**—The Urban District Council invite tenders for switchboard extension, storage battery, etc. Tenders by June 17.

**Partick.**—The Town Council invite tenders for the supply of various plant at their electricity works. Tenders by 12 noon on June 6.

**Edinburgh.**—Tenders are invited for steam and exhaust pipework at McDonald-road electricity supply station. Tenders by 10 a.m. on June 6.

**Madrid.**—The Public Works Department require tenders for carrying out a scheme for an electric tramway for goods transport along Bilbao quays.

**Madrid.**—The Post and Telegraphs Department require tenders for construction and working of a telephone line at Matron (Baleares). Tenders by June 5.

**Cardiff.**—The Asylum Visiting Committee invite tenders for the electric lighting of their new asylum at Whitchurch. Tenders by June 14. See advertisement.

**Bracebridge (near Lincoln).**—Tenders are invited for the installation of fire alarms, telephones, bells, and tell-tale clocks at the Bracebridge Asylum. Tenders by June 7.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

**Brussels.**—The Belgian Government Railways require tenders for a number of lamps and accessories. Specification No. 97 may be obtained from their office at Brussels. Tenders by June 14.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Bristol.**—Tenders are invited for single-phase alternating-current transformers and three-phase to direct-current motor-generators. Full particulars from the City Electrical Engineer, Temple Backs, Bristol.

**Talgarth (Wales).**—Tenders are invited for (1) wiring of the new farm buildings, including the supply and fixing of motors and (2) fire-alarm installation at the Brecon and Radnor Asylum. Tenders by June 7.

**Edinburgh.**—Tenders are invited for the supply of lead-sheathed, paper-insulated copper cables for electricity supply conductors for the year ending May 15, 1906. Tenders by June 5. See advertisement in last issue.

**Moxley (near Bilston).**—The South Staffordshire Joint Small-pox Hospital Board invite tenders for the electric wiring and lighting (including main cables, fittings, etc.) at the small-pox hospital. Tenders by 9 a.m. on June 7.

**London.**—The London County Council invite tenders for the purchase of the modern electricity generating machinery and plant at the generating station, 8 to 16, Sardinia-street, Lincoln's-inn-fields, W.C. Tenders before 3 p.m. on June 5. See advertisement.

**Madrid.**—The Post and Telegraphs Department require tenders for 50 tons 4mm. zinced iron wire and 5 tons 3mm. bronze wire. The maximum price for the iron wire is 580 pesetas and that for the bronze wire 3,400 pesetas per ton. Tenders by June 5.

**Stalybridge.**—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

Digitized by Google

**Lugano (Switzerland).**—Tenders are invited for the erection of an electric power station at Zordola, to be worked by water power. Particulars may be obtained from the town clerk. Tenders by June 9.

**Ossett (Yorks).**—The Town Council invite tenders for the following plant: (Section No. 1) quick-speed engines for direct coupling to dynamos; (2) dynamos, boosters, and balancers; (3) storage battery; 4) switchboard; (5) travelling crane; (6) cables. Tenders by June 14.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Esh (Durham).**—Tenders are invited for erection of electric lighting plant on the road leading from Cornsay Lodge by Commercial-street, Cornsay Colliery, and then by the low road to Hawsteels crossing, being a distance of about 1,600 yards. Tenders to the Esh Parish Council by June 13.

**Glasgow.**—The Corporation invite tenders for the construction of tramway in Dalmarnock-street and Springfield-road from Great Eastern-road to Dalmarnock-road. Specification, etc., can be had on application to Mr. James Dalrymple, general manager, 46, Bath-street, Glasgow. Tenders by 10 a.m. on June 13.

**Bristol.**—The Docks Committee invite tenders for the construction, delivery, erecting in place, fitting, testing, and maintenance for 12 months after completion, of four two-ton movable electric jib cranes, and one three-ton movable electric jib crane to be erected on the adjoining wharf at Canons Marsh. Tenders by June 7.

**Hammersmith.**—The Council are about to supply all electricity to the stands at the Olympia Electrical Exhibition, and invite propositions from bona fide British manufacturers for the hire of the necessary materials for the distribution inside the hall. The materials required will consist of (A) meters; (B) lead-covered and armoured cables; (C) distribution pillars; (D) fuse and switch boxes for exhibitors' stands; (E) continuous-current plant (motor-generators, rotary converters, or steam driven). Tenders by June 2. See advertisement in last issue.

## RESULTS OF TENDERS.

**Islington.**—The Electricity Committee recommend the acceptance of the contract of the Union Electric Company for the supply of 42 Excello flame lamps at a cost of £388. 13s.

**Shoreditch.**—The Borough Council have accepted the tender of W. T. Glover and Co., at £3,234. 6s. 4d., for the supply of 3,800 yards of ·75 high-tension concentric, paper-insulated, lead-covered cable.

**St. Marylebone.**—The Council have ordered from the St. Helens Cable Company 10 miles of ·03 concentric cable at £154. 12s. per mile, 3 miles of ·03 triple-concentric cable at £287. 4s. per mile, 2 miles of ·05 triple-concentric cable at £362. 8s. per mile, and 1 mile of ·1 triple-concentric cable at £474. 8s. per mile.

**Bournemouth.**—The Town Council have received the following tenders for Contract No. 6—11 electric cars: Dick, Kerr, and Co., Limited; British Thomson-Houston Company, Limited; British Westinghouse Electric and Manufacturing Company, Limited (withdrawn); Brush Electrical Engineering Company, Limited. No tender has been accepted so far.

**Birmingham.**—The following tenders have been accepted for the necessary materials and the works of reconstruction of the tramways: Bolckow, Vaughan, and Co., Middlesbrough, 1,660 tons of tramrails with fishplates, £5. 10s. per ton; Hadfield's Steelfoundry Company, Sheffield, special tramway work, £1,708. 10s.; Dick, Kerr, and Co., Preston, reconstructing permanent way, £42,261. 15s. 1d.*; Dick, Kerr, and Co., 200 electric cars, including provision of spare parts and contingencies, £110,411. 12s. *This amount is exclusive of the cost of paving the sides of the roads, which will be carried out by the same firm at the same time for the Public Works Committee; it is also exclusive of the cost of the overhead electrical equipment.

# BUSINESS NOTES.

## TRACTION.

**Swinton.**—The Swinton Tramways (Extension of Time) Bill has been read a third time in the House of Commons.

**Bristol.**—A meeting of the inhabitants of Westbury unanimously resolved to ask the company to substitute electric cars for 'buses.

**Blackpool.**—The receipts from the trams for the period between April 1 and May 18 totalled £4,985, as against £4,539 last year.

**Leven-Kirkcaldy.**—The Commissioners under the Private Legislation Procedure (Scotland) Act have found the preamble of this Bill proved.

**Gilmerton (N.B.).**—A meeting of inhabitants decided to petition the Mid-Lothian County Council to support the proposed electric tramway.

**Doncaster.**—The *plébiscite* on the question of Sunday running has resulted in an adverse vote, the figures being: against Sunday running, 1,536; in favour of same, 564.

**Garcia Renault Electric Cars Co.**—An order for compulsory winding-up has been made with respect to the Garcia Renault Electric Cars and Accumulators, Limited.

**Hastings.**—The Hastings Tramways Bill (except the portions dealing with the Bexhill tramways) has now passed through all the committee stages of the House of Lords.

**Nottingham.**—The Corporation are experimenting with a 20-h.p. Wolseley motor 'bus with a view of testing the respective merits of such vehicles and electric trams for Sneinton.

**Lampeter.**—At a meeting of the inhabitants a resolution supporting the light railway scheme to New Quay was carried with enthusiasm, and it was decided to ask the Cardigan Town Council and the rural district councils to contribute towards the cost.

**Bournemouth.**—The work of constructing the electric tramways to Christchurch and through the suburb of Southbourne has just begun. This will, doubtless, be welcomed by the inhabitants, as at present the journey, which is scarcely four miles, costs 6d. by 'bus.

**Bradford.**—At the meeting of the Tramways Committee the city treasurer reported a profit of £70,000 on the tramways, and after the repayment of sinking fund there remains a disposable balance of £16,000. This is the largest balance which the committee has had.

**Whetstone and Barnet.**—At a meeting of the East Barnet Urban District Council the plans submitted by the Herts County Council for the light railway between these places were considered, and it was decided to forward the County Council certain recommendations as to street widening.

**Halifax.**—The Corporation having obtained powers to construct tramways to Wainstalls, an out-of-the-way district, they decided to apply to the Board of Trade for leave to substitute motor 'buses. A reply from the Board has been received, stating that the Board are not empowered to give the authority desired.

**York.**—The Wolseley Motorcar Company recently conducted some tests with one of their vehicles, and the results are reported to have been highly favourable. There is expected to be an interesting discussion on the part of the Corporation at an early date in regard to the electric tram *versus* motor 'bus question.

**Edinburgh.**—It has been announced officially that the Mid-Lothian County Council has now withdrawn its objections, and consented to the provisional order of the Edinburgh Suburban Electric Tramways Syndicate, Limited. As Dalkeith and Bonnyrigg have also granted their consent, the approval of the whole local authorities on the route has now been obtained.

**Wellingborough.**—The House of Commons Committee on Wednesday rejected the Wellingborough and District Tramroads and Electricity Supply Bill, promoted by the British Electric Traction Company. The company sought powers for an extension of time for the construction of authorised tramways and for power to establish generating stations and supply electric power in portions of Northamptonshire, Bedfordshire, and Huntingdonshire.

**Darlington.**—As the result of the introduction of ½d. fares, the tramway receipts have shown a fall, notwithstanding an increase in the number of passengers. During the four weeks the ½d. fares have been in operation the passengers have averaged 60,000 a week (in a population of 48,000); the receipts, amounting to about £778, show a decrease of some £100 as compared with last year. The inference appears to be that resort should not be had to ½d. stages until a tramway system is well established.

**Metropolitan Railway.**—Orders for 10 electric locomotives, each developing 1,200 h.p., have been placed with the Westinghouse Company for use on their newly-electrified line between Harrow and Baker-street. Experiments with the discarded "Tube" locomotives proved that these engines were not sufficiently powerful for the work on the Metropolitan line. The same locomotives will be used on the Metropolitan section of the Inner Circle for goods traffic and for the steam trains coming off the Great Western and Hammersmith lines, *viâ* Bishop's-road.

**London Southern Tramways Co.**—Several witnesses having been examined in support of this company's Bill seeking power to reconstruct their system electrically, the chairman (Mr. T. G. Ashton) intervened, and said there was no necessity to proceed further, as the committee were of opinion that the preamble was not proved. Mr. Vesey Knox protested that it was contrary to the Standing Orders and the practice of the House to decide against a Bill before hearing the whole of the promoters' case, but the committee adhered to their decision, and the scheme was rejected.

**Seaham Harbour.**—At the monthly meeting of the Seaham Urban District Council, the Finance and General Purposes Committee reported that negotiations with the tramways company had resulted in the company deciding to promote a Bill enabling them to construct a line through Murton Colliery and Seaham Colliery to Seaham Harbour, in lieu of the line which they proposed to construct from South Hetton, around by Easington, to Seaham Harbour, and that the company proposed also to make a line of tramways from Seaham Harbour to Ryhope.

**Bury.**—On account of the increased demand for energy, the Tramway Committee in November appointed representatives to confer with the Electricity Committee on the question of price. The result of the negotiations was a decision to charge 1½d. per unit for the half-year ending September last, 1·4d. per unit for the quarter ending December, and 1·3d. per unit for the quarter ending March 31. A further reduction to 1·2d. per unit came into force on April 1. The difficulty in the way of a further concession appears to be the abnormal traffic on the occasion of football matches, which necessitates additional generating plant for such days only.

**Ramsgate.**—An accident occurred to one of the trams at Ramsgate last week. Apparently, on descending a hill leading to the harbour, the brakes failed to act, and the car ran at a great speed and dashed into a grocer's shop. The passengers jumped from the car and escaped serious injury. The shop was wrecked, and a seven-year-old daughter of the manager was found with her head terribly injured. Her life is despaired of. The driver of the car was taken to a surgery in an unconscious condition, having sustained head and chest injuries, and the conductor was also removed with his cheek bone laid bare and a scalp wound. There were a number of other injuries of a less serious character suffered by passengers.

Digitized by Google

**Birmingham.**—The Tramways Committee of the City Council in their report state that, under the terms of the agreement with the City of Birmingham Tramways Company, the latter have informed the committee that the order in which they desire the reconstruction of the undermentioned tramways under lease to them to be proceeded with is as follows: (1) Saltley and Nechells route; (2) King's Heath route; (3) Moseley-road route; (4) Stratford-road route. The accounts for the year ended March 31 last show a gross profit on the Steelhouse-lane route of £8,764 1s. 2d., and after providing for interest on capital and contributions to sinking fund, there remains a net profit of £5,800. 17s. 9d., which the committee have carried to the reserve fund.

**Belfast.**—At the meeting of the Tramway Committee on Monday, a deputation from the National Telephone Company attended. They stated that the company were willing to meet the committee so far as they could, but they asked the latter not to adhere to their decision that all the telephone wires along the tramway routes must be placed underground, as this would entail great hardship and expense. A lengthened discussion ensued, but ultimately it was decided that in order that the position of the Corporation on the question might be accurately ascertained, the town clerk should submit a case to counsel. The Lord Mayor reported on behalf of the sub-committee which had visited the depôts that the work was proceeding satisfactorily, and the city surveyor intimated that the reconstruction of the tramways system was being carried out in a manner which met with his approval. The consideration of the question of fares was further adjourned.

**Blackburn.**—The sixth annual report of the Corporation tramways shows receipts amounting to £48,875 against working expenses of £30,580, leaving a gross profit of £18,295. Interest on loans absorbs £8,599 and sinking fund £12,488, showing a deficit on the year of £2,792. The mileage passengers receipts and receipts per car mile for the past and the preceding year respectively are as follows: 986,953 and 951,484 miles; 8,661,720 and 7,742,692 passengers; receipts, £47,118 and £43,374; receipts per car mile, 11·46d. and 10·94d. The cost of maintaining the rolling-stock shows a marked decrease as compared with last year. The consumption of power shows a slight decrease, being 2·77d. per car mile against 2·81d. for the previous year. This is attributed to the bonus system to drivers. The joint managers (Messrs. Johnston and Cowell) do not think the general expenses can be materially reduced, except in regard to the charge for energy, which represents over 30 per cent. of the total expenditure.

**Inquest.**—An inquest was held at Gateshead on Monday into the death of John Henry Fenwick, a bricklayer's labourer, employed on the North-Eastern Railway, who met his death by taking hold of a live wire at Gateshead railway shop. Matthew Waller, an electric crane driver, said he shut off the current to the electric crane at 4.45 on Friday afternoon. He tried the switch, and everything was safe when he left at five o'clock. Another witness, who was working with the deceased, said that on the side of the walls on which they were working were three wires that conveyed the current to the crane. After deceased had gone up the ladder he heard a shout, and saw him grasping one of the wires in his right hand. He was standing on the electric crane. He did not know what the deceased was doing to get hold of the live wire. He thought that whilst standing on the crane he must have grasped the wire to save himself from falling. Dr. Robinson said that death was the result of shock due to the passage through the body of the electric current. A verdict of accidental death was returned.

**Municipalisation in the States.**—Mr. Dalrymple, the manager of the Glasgow Corporation tramways, is on his way to Chicago to assist the mayor of that city in the work of taking over the tramway systems. The decision of the Chicago Corporation to municipalise the trams created something of a sensation in the States. Mr. Dalrymple was met at New York by several members of the Municipal Ownership League of Chicago, who came from that city to welcome him, and also by a deputation of New York city officials. He was given a public reception at the Hoffmann House last night, at which Mr. McClellan, mayor of New York, presided. In an interview Mr. Dalrymple said that he was going to Chicago without delay, as he was anxious to make his absence from Glasgow as short as possible. On being asked his opinion of the tramways system of New York he criticised it severely. He did not think they were worthy of a great city, and declared that they were not nearly as good as Glasgow possessed. Much of his criticism was directed to the lack of discipline on the part of the tramway employés.

**Leicester.**—At a special meeting of the Corporation on Tuesday Councillor Flint moved the adoption of the report of the Tramways Committee, which included the report of the borough surveyor on the cost of the electric tramway scheme. The total expenditure authorised by Parliament was £580,747. The amount estimated to be spent on the work which had been actually done was £475,000, and the actual cost had been £469,746. This was a saving of £30,219, but there were other items in which they had exceeded the original estimate, amounting to £24 000, and the net saving on the estimates was £5 274. The total amount unexpended of the original estimate was £111,000, this including the saving on the work done. The parliamentary estimate was for 42 miles of track and 90 cars. The routes actually constructed totalled 36½ miles of track. The figures, worked out on the basis he had given, came out at £12,869 per mile, while the borough surveyor's estimate was £13 014 per mile, the total saving being £5,275. Councillor Flint remarked that, considering the admirable system they had acquired, he thought the result must be deemed highly satisfactory. The report was adopted.

**Railway Motor 'Buses.**—At the meeting of the Municipal Tramways Association at the Westminster Palace Hotel the committee considered the amendments made by the House of Commons Committee in the North-Eastern Railway Bill, with a view to the protection of the Hull and Newcastle Corporations regarding the running of railway motor omnibuses. The committee of the association decided that the amendments did not go far enough to satisfy the requirements of corporations owning tramways. Under the circumstances it was resolved that when the Bill is set down for consideration on the report, an attempt should be made to still further limit the powers of railway companies with regard to motor omnibuses, and a motion is to be made in the House of Commons on that subject to the effect that "notwithstanding the powers granted by Section 54 of the Bill, nothing contained in that section shall authorise a company to run any railway omnibuses in a borough or urban district provided with a system of tramways, otherwise than for the conveyance of railway passengers, passengers' luggage, and mails to or from a station or hotel of the company, without the consent in writing of the local authority for such a period as may be therein specified."

**Proposed Electric Railway.**—A meeting will be held in Manchester early in June with a view to ascertaining whether or not sufficient local support will be forthcoming to justify the promotion in the next session of Parliament of a Bill asking for powers to construct the South Manchester Electric Railway to connect the outer Cheshire suburbs and the city. The proposed railway will be an express suburban cross-country "belt line" of standard gauge and constructed as a light railway, the main line being about 16½ miles long, and the branches bringing the total mileage up to about 26 miles. The line is intended for both passenger and goods traffic, and will transversely intersect and connect all the existing southern trunk lines from Manchester to London. It will commence from a proposed new centrally situated terminal station on the southern outskirts of the city, thence running about seven miles south-westwards direct into Cheshire, and thence through the outer belt of North Cheshire suburban residential districts, at an average radius of nine miles from the Manchester Town Hall, and terminating at a proposed new station at Hazel Grove, adjacent to the Stockport Corporation tramways terminus, and to the Midland Railway Company's new main-line station.—*Macclesfield Courier.*

**South Staffordshire Tramways Co.**—At an extraordinary general meeting last week, the agreement with the Corporation of Wednesbury for the sale to the latter of the portion of the company's undertaking within the borough was confirmed. The length of line concerned is about four miles. It was also resolved that the proposed agreement between the company and the South Staffordshire Tramways (Lessee) Company be approved. The Chairman said that the net result of the agreement was that the claim of the lessee company had been reduced from a possible £55,000 to £51,500, but some reconstruction work still remained to be carried out. The fifteenth ordinary general meeting followed, when the Chairman stated that the revenue for the half-year amounted to £1,257. After deducting all expenses chargeable to revenue, there remained a profit of £663, which it was proposed to apply in the payment of a dividend of 1s. 8d. per share on the preference shares, which would absorb £633, leaving £35 to be carried forward. This dividend was against a dividend of 1s. 4d. to June 30 last. Certain arrangements had been made which would give them a saving of about £550 a year in expenses of administration, or enough to increase the dividend on the preference shares by 1s. 5d. per share. The only other municipal authority besides Wednesbury with which they were in negotiation was Dudley, and he hoped to be able to report something definite as to that by the next meeting. The report was unanimously adopted.

**London County Council.**—At the meeting of the Council on Tuesday the Highways Committee recommended that sanction should be sought in the parliamentary session of 1906 for laying temporary tramway tracks. Another recommendation was that £7,150 should be voted for the erection of the Streatham sub-station. An important subject on the agenda was the construction of the following new tramways: (1) from Camberwell-green, *via* Denmark-hill, Champion-park, Grove-lane, Dog Kennel-hill, and Grove-vale, to the junction of Lordship-lane and Crystal Palace-road; (2) from the terminus of the authorised tramways in Lordship-lane, *via* Lordship-lane and London-road, to Dartmouth-road, Forest Hill; (3) from Grove-vale, *via* Goose-green, East Dulwich-road, and Peckham Rye, to Stuart-road, Peckham; (4) from the existing London County Council tramways in New Cross-road, *via* Lewisham High-road, Loampit hill and vale, and High-street, Lewisham, to Rushey-green; (5) from the existing London County Council tramways terminus in Trafalgar-road, Greenwich, *via* Blackwall-lane, to a point near Blackwall Tunnel. The estimated cost is £302 950 for the track, including cables and ducts, £26 200 for cars, £18 500 for car-sheds, and £14,300 for sub-stations. Owing to the amount involved, a decision was adjourned for a week in accordance with standing orders. The Finance Committee are in communication with the Highways Committee on the matter, as the former think that, owing to the expense involved in the approaching reconstruction of the northern system, other outlays should be curtailed as much as possible. The receipts for the week ended May 20 totalled £14,345 against £11 451 last year, and for the period from April 1 to May 20 the amount was £100 182, against £78,458.

**New York.**—The Rapid Transit Commission at its meeting on May 12 adopted all the tunnel routes informally chosen a week ago, with the exception of that for a four-track subway in Thirty-fourth-street. The commission decided to run the new Lexington-avenue route through Thirty-fifth and Thirty-sixth streets, as originally proposed, and leave Thirty-fourth-street as a route for an independent cross-town line or moving platform. This modification was brought about by a letter signed by Max E. Schmidt, Stuyvesant Fish, and Cornelius Vanderbilt, representing the Continuous Transit Securities Company. The letter said that, subject to possible damages to abutting property owners, the Interborough Rapid Transit Company would be glad to have a moving platform on the Forty-second-street spur of the Third-avenue elevated road. The engineers for the New York City Railway Company said they did not longer desire a four-track route through Thirty-fourth-street, but preferred the route as originally laid down, with

Digitized by Google

two tracks in Thirty-fifth and two in Thirty-sixth street, between Lexington and Fifth avenues. The Thirty-fourth-street cross-town line will be built in two sections, one section being from the East River to Ninth-avenue, and the other from Ninth-avenue to the North River. The commission authorised the extension of the Interborough system from the present northern terminus on the west side to Van Cortlandt Park, Mr. Bryan saying the cars would be running there in a year's time. Acting-engineer Rice said that trains would be running down Broadway to the Battery within six weeks. Mr. Rice also said that as soon as leaks were stopped in the tunnel under the Harlem in about three weeks, it would be put in operation. The Interborough Company's proposition to four-track the Second-avenue elevated track was rejected. On the four-tracking of the Fulton-street, Brooklyn, subway, a letter was read from August Belmont saying that the Interborough was willing to pay half the cost if the city would pay the cost of the connection. This offer was accepted The city will pay £300,000 and the company £100,000.—*Electrical World* (New York).

## LIGHTING AND GENERAL.

**Halifax.**—The Corporation last year made a profit of £5,825 from their electricity works.

**Sale of Plant.**—Particulars of a sale of a complete direct-coupled steam set appear in another column.

**Penrith.**—The Urban District Council have decided to transfer their electric lighting order if a suitable offer is received.

**Rubber.**—An association has been formed in France to promote rubber production in the Congo and other French colonies.

**Grangetown-in-Cleveland** —Plans have been prepared for the erection of an electric power station here for the supply of Tees-side district.

**Malton.**—The Town Council's contract with the gas company having expired, it is now proposed to ask for tenders for lighting by gas or electricity.

**Blackburn.**—Last year's working of the electricity department shows a net profit of £251, after providing for £14,297 interest and sinking fund.

**Johannesburg.**—An international exhibition is to be held in 1907, under the patronage of the Government and the Chambers of Mines, Commerce, and Trade.

**Elgin.**—The Town Council have remitted to a committee to report on the best method of taking the necessary steps for the introduction of electric light to the burgh.

**Argentine.**—There is said to be a good opening at Rosario for electric plant and appliances. The Harbour Works Company are just constructing a central station.

**Batley.**—The loss in the electricity department of the Corporation has been reduced to £340 for the past year, as compared with £854 for the previous eight months.

**Pitlochry.**—Enquiries are being made with the view of ascertaining what local support can be obtained in connection with the proposal to introduce the telephone to the district.

**Hanley.**—In consequence of the electrical engineer's report on the expenditure necessary for mains, tools, meters, etc., application is to be made for sanction to borrow £11,000.

**Nicaragua.**—The Government have granted a monopoly for utilising the Tipitape Falls for generating electricity to the Nicaraguan Finance and Improvement Company.

**Western Telegraph Co.**—An interim dividend has been declared, payable on June 24, of 3s. per share, or at the rate of 6 per cent. per annum, free of income tax, for the quarter ended March 31.

**Barnstaple.**—The Town Council are advertising in the local papers to the effect that where, during alterations in premises, it is found necessary to interfere with any electric apparatus, notice thereof must first be given to the electric engineer.

**Dunfermline.**—The Fife Electric Power Company's station at Townhill has been completed. The streets in the northern part of Dunfermline are being opened up for cable-laying. The company are under contract to supply several factories in the city and collieries in the district.

**New Works.**—The Simplex Steel Conduit Company inform us that, owing to enormous increased demand for their conduits and fittings, they have found it necessary to build entirely new factories at Garrison-lane and Maxstoke-street, Birmingham, and have made special arrangements for quick delivery.

**Newtown Telephones.**—The Urban District Council have rescinded the following resolution: "That inasmuch as the Council have consented only to be liable for £120, to be made up in Newtown, they cannot now see their way to increase their liability, which the new guarantee proposes to do."

**Electrical Plant for Japanese Dockyards.**—A Reuter's telegram announces that contracts to the amount of 5,000,000 dol. have been placed in the U.S.A. for shipment with all dispatch of electrical equipment machines, tools, and installation in the Japanese Government shipyards and arsenals.

**Hessle.**—The Court of Referees of the House of Commons on the 30th ult., after hearing an objection taken by the promoters of the Hessle electric lighting provisional order to a petition which the Hessle Gaslight and Coke Company sought to present in opposition, decided to allow a *locus* on the ground of competition.

**London County Council.**—On Tuesday it was agreed to lend the Hackney Borough Council £11,083 for electric light installation and the Poplar Borough Council £3,660 for electric lighting purposes. Sanction was also given to the borrowing of £1,782 by the Islington Borough Council for electric lighting purposes.

**Swansea.**—The Council have decided to ask the National Company what steps they are taking with regard to Justice Buckley's decision on the question of intercommunication. The Postmaster-General is enquiring as to the number of present Corporation exchanges, the number of subscribers, and the amount of capital expended.

**Cape-to-Cairo Rail and Telegraph.**—Messrs. Pauling and Co., contractors for the extension of the Cape-to-Cairo Railway beyond the Victoria Falls, have received a cable from their representatives in Rhodesia to the effect that the railway and telegraph lines have reached Kalomo, the headquarters of the North-Western Rhodesia Administration.

**Walsall.**—An enquiry has been held into the application of the Town Council for sanction to borrow £5,500 for electric lighting. The loan is mainly required to replace the present plant at the station in the centre of the town by larger machinery, the demand having so increased that the plant is already overtaxed, and will be quite unequal to the demand of the coming winter.

**New Branch.**—The Weston Electrical Instrument Company, of Newark, N.J., U.S.A., have opened a branch office and laboratory at Audrey House, Ely-place, Holborn, E.C., under the management of Mr. A. Davy. We are informed that catalogues describing the firm's standard voltmeters, ammeters, wattmeters, ohmmeters, etc., for portable testing work, laboratory standard instruments, switchboard instruments, etc, will be posted on request.

**Finchley.**—The fire which broke out in the boiler-house of the electricity works on Wednesday morning last week damaged the woodwork, and the roof collapsed. The whole of the works are insured, and the damage is roughly estimated at about £1,500. The facts having been greatly exaggerated in the London Press, Mr. Calvert, the electrical engineer, caused the public lamps to be switched on in the course of the day, so as to show that there was no need for alarm.

**Anglo-Chinese Telegraph Convention.**—A convention was signed at the Wai-wu-pu on May 23 on behalf of China and Great Britain by Sir Ernest Satow and Na-tung renewing Article 16 of the Burma Convention of 1894 respecting a junction between the Burma and China telegraph lines, with a modification of rates to meet the general lowering of rates of submarine cables. The negotiations were conducted by Mr. Berrington, of the Indian Telegraphs, and Chu Pao-fay, of the Chinese Telegraphs.

**Hammersmith.**—The last report shows that the premises of 13 additional consumers, representing a maximum of 315 8-c.p. lamps, have been connected to the mains, 10 consumers have been disconnected, making the present number of consumers 1,585. An application of the Postmaster-General for permission to the placing of an underground telegraphic line along the south side of Uxbridge-road, from the existing line at the east corner of Godolphin-road to 101, Uxbridge-road, has been agreed to.

**Shipley.**—The accounts of the Urban District Council electricity department for the year ended March 31, 1905, with which we will deal more fully in another issue, give the total costs at £3,490, an amount which is arrived at by deducting £500 for the cost of repairs, renewals, and attendance to public lamps, and £320 the cost of materials sold, etc., making a total of £820 to be deducted from the amount of £4,310, representing the actual total costs. The net profit of £562 on the year's working is carried forward to provide for bad debts.

**Sunderland.**—The annual report of the Corporation's electricity undertaking states that on March 31 an equivalent of 289,800 8-c.p. were connected, as compared with 197,683 the previous year, an increase of 46 per cent. The number of units sold was 4,772,913, as against 3,508,139, equivalent to an increase of 36 per cent. These were distributed as follows: lighting, 1,080,330; power, 1,661,586; tramways, 1,707,261; and public lighting, 323,736. The total cost of production per unit was reduced by 10 per cent. as compared with the previous year.

**Hull.**—The Chairman of the Electric Lighting Committee (Mr. Millington), in a recent report on the electric light undertaking, states that there are at present 2,453 consumers. Electric light consumers increased by 185 and motor users by 65. The gross receipts for the year amounted to £39,867, and the balance £22,700, with the actual profit of £4,980. During the year negotiations were completed for the supply of large quantities of electricity in bulk. The Hull Chamber of Trades have appointed a sub-committee to watch the telephone question.

**Private Bills.**—In the House of Lords the following Bills have been read a third time: Weybridge-upon-Thames Electric Supply, Chelsea Electric Supply, North Metropolitan Electric Power Supply, Gosport and Fareham Tramways, Hastings Tramways, South Lancashire Tramways, Baker-street and Waterloo Railway, Edgware and Hampstead Railway, Charing Cross, Euston, and Hampstead Railway, and the London United Tramways (Extension of Time). In the House of Commons the following Bills were read a third time: Great Northern, Piccadilly, and Brompton Railway (No. 1) and the Mexborough and Swinton Tramways Extension.

**Blackpool.**—The electrical engineer (Mr. C. Furness) in his report for the month of April shows a decrease in total works output over the corresponding month last year of 14,039 units, made up as follows: Private lighting—1904, 72,418; 1905, 76,864; increase, 4,446. Public lighting—1904, 13,785; 1905, 12,801; decrease, 984. Corporation tramways—1904, 103,222; 1905, 90,238; decrease, 12,984. Lytham and St. Annes Tramways—1904, 10,269; 1905, 5,742; decrease, 4,517. Total for month—1904, 199,684; 1905, 185,645; net decrease, 14,039. The engineer attributes the decrease in output to the Corporation tramways to the service along Lytham-road being suspended.

**Stock Exchange.**—The Stock Exchange Committee have ordered the undermentioned securities to be quoted in the official list: British

Digitized by Google

Columbia Electric Railway Company's £115,000 5 per cent. cumulative perpetual preference stock, in lieu partly of the 5 per cent. cumulative perpetual preference shares now quoted; South Metropolitan Electric Light and Power Company's further issue of 35 368 7 per cent. cumulative preference shares of £1 each, fully paid, Nos. 200 001 to 235 368, and £48 292 4½ per cent. first debenture stock. An application has been renewed to allow the City of Wellington Electric Light and Power Company's £75 000 5 per cent. registered first debentures of £50 each, Nos. 1 to 1,500, to be quoted in the official list.

**Shoreditch.**—Some interesting proposals are before the Lighting Committee with regard to erection, in connection with the refuse destructor, of a clinker crushing and sorting apparatus. This would save the cost of carting clinker from the destructor yard, and at the same time turn the clinker into a saleable article. The committee, in conjunction with the Highways Committee, have inspected a similar plant at work at Stepney, which consists of a crushing mill, elevator, and three-grade sifter. The estimated cost, including erection, is £975. Judging from the experience of those authorities who have such an apparatus at work, it is estimated that the capital cost of the plant will be covered in the first year by the saving on cartage of clinker and revenue from the sale of sorted clinker. It is also proposed to increase the stock of demand indicators.

**Tottenham.**—The tender of Messrs. Graham, Morton, and Co., Limited, has been accepted by the Tottenham and Edmonton Gas-light and Coke Company for the supply and erection, to the designs of Mr. Arthur Edward Broadberry, the company's engineer, of a new retort-house, a coke storage tank, an overhead coal storage tank with measuring chambers and hydraulic actuating gear, piping valves, etc., also a coke storage tank in the coke yard at the north end of the house, and the supply and erection of coal and coke handling plant, comprising: (1) coal-handling plant from truck into coal tanks; (2) auxiliary plant for putting coal into store; (3) gravity bucket conveyor for conveying coke from storage tank in yard to storage tank for C.W.G. plant; (4) hot-coke conveyor from retorts to coke storage tank; (5) coke-screening plant; (6) conveying plant from coke storage tank top to coke yard; (7) engine in duplicate for driving the above plant.

**Electrical Supply.**—The Croydon Corporation Bill was before Lord Newton's Select Committee of the House of Lords on the 26th ult. The Bill authorises the construction of certain linking-up tramways in Croydon, and makes further provision for the sanitation and good government of the borough. It has been amended and passed by the Police and Sanitary Regulations Committee of the House of Commons, and one clause was opposed. Under it it was proposed that if the local authority for any district adjacent to the area which the Corporation were for the time being authorised to supply with electrical energy, or any company were authorised to supply energy within such district, the Corporation and these authorised undertakers "may enter into and carry into effect agreements for the supply of electrical energy in bulk by the Corporation to such local authority or company." The County of London Electric Supply Company, the South Metropolitan Electric Tramways and Lighting Company, and the South London Electric Supply Corporation successfully opposed the clause. The other clauses were adjusted, and the preamble having been proved, he Bill was ordered to be reported to the House for third reading.

**Eastbourne.**—An enquiry has been held into the Council's application for sanction to a loan of £2,518 for the purpose of laying two additional feeder cables and making alterations to the switchboard and sub-stations, necessitated by the growing demand on the electric lighting works. The electrical engineer, Mr. J. Kempe Brydges, stated that the load last year on the plant was 743 kw., and it would be 870 in 1905 if progress was maintained at the same rate as hitherto. The four existing feeders between the works and the town were fully loaded last winter. The Electric Lighting Committee proposed to lay two additional feeders of the same size as the existing ones, in order to avoid future excavations under the path from the works to the town, a distance of 1½ miles. Increased capacity is to be provided for future demands. Instead of only laying these two feeders and drawing them into a two-way pipe, allowance has been made for an eight-way pipe for a part of the distance and a six-way pipe for the remaining part. Right up to the town there would be four ducts into which feeder cables could be drawn as they were required in future. This would obviate taking up the road again for some years. The ducts were of glazed stoneware, and suitable manholes had been provided at intervals. He submitted the following estimate: estimated cost of ducts, £750; trench work and laying ducts, £326; inspection boxes, £90; 5,500 yards of cable, £1,100; drawing-in and joining cable, £68. 15s.; extension of switchboard and two sub-sections, £90; contingencies, £93. 5s.—total, £2,518.

**St. Marylebone.**—The Finance Committee reported at the last meeting of the Borough Council that they had received a memorandum from the Electric Supply Committee with a report from the consulting engineer and accountant, with reference to the probable further requirements on capital account, from which it appeared that to provide for such expenditure it would be necessary to take up further instalments of the sanctioned loan of £433 800 from the London County Council as follows: A third instalment of £50,000 in June next, and a fourth instalment of £100,000 in July prior to the summer vacation. They were making application to the London County Council for such further advances, and informed the Council accordingly. The committee's recommendation that the seal of the Council should be affixed to mortgages of the general rate to secure the repayment to the London County Council of the sums at £3. 7s. 6d. per cent. within the period sanctioned by the London County Council was agreed to, as was also a proposal of the committee to continue the present rates of charges for current until the end of the year, or until such time as they shall have obtained sufficient data to revise the same. In answer to a question, the Town Clerk said the Central Electric Company had not obtained any powers by their Parliamentary Bill to supply electricity in the borough, but they had power to lay additional trenches for their generating stations. With regard to the Metropolitan Electric Supply Company, they also had no power to supply current, except for traction purposes to any railway that might pass through.

**Leeds.**—The receipts of the electric lighting department of the Corporation for the past year from sales for lighting were £73 597, and for power £10 819 a total of £84,416, as compared with £75,720 the previous year. The working expenses, taxes, and costs incidental to change of system amounted to £28,364, as against £25,183 a year ago. The gross profit of the department was £56 052, a large increase on the previous year's figures, which were £49,537. Interest and redemption fund charges increased from £46 106 to £55,770, making a net surplus of £282 for the year, against the surplus of £3 430 in 1903 4. The total number of units sold last year was 7,030 681, and the average price paid per unit was 2 88d. As the expenses per unit, including interest and sinking fund, amounted to 2 87d., there was a surplus of only ·01d. per unit, as against ·13d. in the previous year. Capital to the amount of £64.795 was expended during the year, and the total capital consumed by the undertaking to date has been £822,122. The 35-watt lamps have been increased during the year by 29,355, the total number now installed being 264,628. The units sold for private lighting amounted to 4,871.731, and for street-lighting to 217,997, the revenue from the purely lighting department being £73,597, or 5s. 10·55d. per lamp installed. The units sold for power and heating amounted to 1,940,953, the revenue in this branch being £10.819, or £3. 5s. 8d. per horse-power installed. The aggregate horse-power installed at the end of the year was 3 904, an increase of 1 001 over the previous year. The accounts were presented to the Electricity Committee yesterday, Alderman E. Matheson presiding.

**London Wiring.**—When the Police and Sanitary Regulations Committee of the House of Commons (Mr. J. W. Wilson in the chair) resumed consideration of the electricity clauses of the General Powers Bill of the London County Council on the 25th, the Chairman stated that the committee's decision (reported in our last issue) had been entirely unanimous. Mr. Freeman, K.C., on behalf of the London County Council, stated that, in consequence of the committee's decision, the words "whether directly or otherwise," having relation to the manner in which a borough council might charge for wiring, fittings, and apparatus, had been struck out of Clause 63. The County Council and the gas companies had agreed to the following provisos to the clause: (1) Provided also that every such council shall so adjust the charges to be made by them as aforesaid as to meet any expenditure by them under the powers of this section, including interest upon any moneys borrowed under and for the purposes of this part of this Act and payments to sinking funds in respect of such moneys; (2) every sum charged by any such council to a consumer in respect of the wiring and fitting of the premises of such consumer and the supplying of wires, fittings, motors, and apparatus shall be clearly stated on every demand note by such council for payment for electrical energy supplied to such consumer distinct from the charge for such energy. The total sums received and expended by any such council under this part of this Act in each year, including the amount required for interest on and payments to sinking fund, in respect of any moneys borrowed, shall be separately shown in the published accounts of the electric lighting undertaking of such council for such year. The committee assented to the amendment in Clause 63 and the new provisos, and inserted them in the Bill.

**Gloucester.**—The annual report of the city electrical engineer, Mr. W. J. Bache, M.I.E.E., which was presented at a meeting of the City Council on Tuesday, stated that 71 new consumers have been added, and the number of 8-c.p. lamps now connected is 37,276, an increase during the year of 8 378 The capital expended on the undertaking has increased from £67,276 to £75,240. and this is almost entirely on account of the light railways plant. The amount set aside for interest and sinking fund is £797 higher than in the previous year, and is just under 6 per cent. on the capital. The total expenditure on revenue account, apart from financial charges, is £4,872. 0s. 8d. The total cost of generation and distribution has largely decreased, owing to the increase in the number of units sold. Last year the average cost per unit was 1·68d., and it has now fallen to the very satisfactory amount of ·997d. There are very few stations of similar output producing current so cheaply, and it is entirely due to this fact that, in spite of the very low scale of charges, the undertaking shows such a substantial profit. The revenue of the undertaking has amounted to £10,409. 7s. 9d., and the gross profit is £5 537. 7s. 1d., or 7½ per cent. on the capital outlay. Financial charges rose to £4,448. 12s. 4d., leaving a balance of £1,088. 14s. 9d., which is net profit, and will go to reduce the accumulated deficit of £1,858. 13s. 10d. This now stands at £769. 19s. 1d., and there should be no difficulty in entirely wiping this out next year. The total amount of capital repaid out of revenue is now £5,078. 19s. 5d. An enquiry has been held into an application by the Council for sanction to borrow £12,100 for extensions at the electricity works, consisting chiefly with the enlargement of the station and the installation of three new boilers and other plant. The proceedings were purely formal.

**Burnley.**—The financial returns of the electricity works for the past year ending March make a very satisfactory show. At the beginning of the 12 months it was estimated that the surplus would be £7,598, including a charge of 1½d. for traction, but after then the charge was reduced. Out of that estimated profit it was proposed to place £3,000 to the reserve and depreciation fund, put aside £500 for contingencies and hand over £4,098 towards the borough fund in reduction of the rates. It transpires now that the actual profits of the department were £11,000. Out of these, a further remission of a farthing per unit has been granted to the Tramways Committee for the current used during the year, equal to £2,400. The same provisions of £3,000 for reserve and depreciation and £500 for contingencies are made, leaving £5,100 to go towards

Digitized by Google

the rates instead of £4,098, as anticipated. Mr. R. Birkett, the electrical engineer, is to be congratulated on the results, which are due to a reduction in the works cost per unit. These he has brought down from 1·02d. per unit to under ·7d., and with perhaps one exception this average will be the lowest in the country. The profits of £11,000 on a capital expenditure of £92,000 gives a gross surplus of 12 per cent., which also is unsurpassed except by one or two towns in Great Britain. Mr. Birkett, who is leaving next month for Southend-on-Sea, leaves behind him a magnificent record, and takes a good recommendation to his new office. Already the reduction in charges recently decided upon, and which place Burnley amongst the lowest in Great Britain, are: for light, 3½d. from 4d. per unit; motive power and heat, 1¾d. per unit for first hour, from 3d. and 1d. after; 1½d., from 3d., for public lighting; whilst the tramway current is also further reduced to 1·45d. per unit. Since Mr. Birkett took charge the surpluses have gradually increased from £700 to £11,000.

**Birmingham.**—The Electric Supply Committee in their last report state that the number of units sold during the year ended March 31, as compared with the previous year, was as follows: units sold year ended March 31, 1905, 4,645,027; year ended March 31, 1904, 4,367,164; money value, £77,195 (£69,421). This means an increase of 6·36 per cent. in the units sold, and an increase of 2·56 per cent. in the money value. The small increase in money value is partly due to the fact that, while this year the reduced charges approved by the Council were in force during the fall year, they were only in force during the last three quarters of the previous year. The revenue account shows a credit balance of £39,573. 12s. 7d., as compared with £36,939. 17s. 8d. for the previous year. It is seen from the revenue account that the works cost again show an improvement. The total cost of production works out at 1·584d. per unit, as against 1·742d. in the preceding year, a reduction of 0·158d. per unit. The net result of the year's working, after paying interest and sinking fund charges amounting to £28,784. 5s. 3d., is a surplus of £10,789. 7s. 4d., compared with £10,412. 4s. 7d. in the preceding year. The committee, following the course approved by the Council last year, have carried this amount to the statutory reserve fund. Having regard to the committee's heavy commitments in connection with the extension of the undertaking, necessarily involving some payment of interest and sinking fund before the capital becomes profit earning, they still feel that it would not be wise to recommend any other method of disposing of the profit. The total length of new mains laid during the year was 11,050 yards, as compared with 10,051 last year. The lamp and motor connections during the year were equal to a net addition of 16,168 16-c.p. lamps, against 12,499 last year. The committee report that the following tenders have been accepted in connection with this work: Sapcote and Sons, foundations £15,777, buildings £88,689; Bellis and Morcom, engines £52,599. 17s., extensions of galleries, etc., £478; Dick, Kerr, and Co., direct-current generators, £6,685; British Westinghouse Company, alternating-current generators, £3,765; Jessop and Appleby, cranes, £1,770; New Conveyor Company, coal and ash conveying plant, £5,840; British Thomson-Houston Company, direct-current switchboard, £13,685. 10s.; Babcock and Wilcox, boilers, £15,638; F. Green and Son, fuel economisers and flue damper, £2,294; Stewarts and Lloyds, Limited, pipework, £4,761. 18s.; W. H. Allen, Son, and Co., Limited, circulating-water pumps, £1,430. It is not expected that, taken as a whole, the cost will materially exceed the estimate submitted to the Council. Satisfactory progress has been made both in the erection of the buildings and in the manufacture of the plant. The builders' contract provides for the completion of the building by Nov. 30 next.

**South Shields.**—The annual report of Mr. J. H. Cawthra, the borough electrical engineer, contains the following figures of the working of the Council's electricity department: The amount expended up to March 31, 1904, was £149,366, and during the past 12 months additional expenditure out of the capital account amounted to £2,481, making the total to date £151,838. The gross income for the year amounted to £13,132, an increase of £967 over 1905, and the working expenses were £6,935, an increase of £300, leaving a gross profit of £11,196. Out of this amount the following statutory requirements had to be met: Interest on loans, £4,893, and sinking fund, £4,231, a total of £9,130. Deducting these amounts from the gross profit, there is left a balance on the year's working of £2,065. There is a further deduction to be made of £77, representing loss on Holborn Quay, thus reducing the balance to £1,988, as compared with £1,603, at the end of the previous 12 months. The number of units sold to consumers was 1,385,393, as against 1,299,289 during the previous year, an increase of 86,104. The kilowatt capacity of the plant installed is the same as 12 months ago, and quite sufficient to meet the requirements of the borough, as far as energy for lighting purposes is concerned, for some two or three years, and the number of lamps connected have been increased by 5,372, making a total of 59 209. There are now 1,117 consumers, as compared with 1,010 12 months ago. The maximum load in the station at any time during the past winter was on Dec. 31, when it was 953 kw. The number of arc lamps in use for purposes of public lighting is 91, this being an increase of three, while the number of ordinary gas standards which have been converted into electric make a total of 462, an increase of 30 during the past 12 months. The average price per unit obtained for current supplied to private consumers was 3·8d., while the price obtained for street-lighting was 1·61d. per unit. Respecting the works costs, the electrical engineer points out that in South Shields, with an output of 1,385,893 units, it works out at ·61d., and therefore can claim to be the third lowest of all electrical undertakings in the United Kingdom, either companies or municipal, supplying electric energy for lighting and power purposes only. No portion of the past year's profits have been allocated to the reserve fund, which now stands at £2,491, and the engineer strongly recommends the committee to place the whole balance of the net revenue account, £2,094, to reserve. He states that an ample reserve fund is very necessary, and taking into consideration the fact that the works have been running nearly nine years, there could be no doubt whatever that the reserve fund was abnormally low. Every opportunity, he says, should be taken of building up the fund to an adequate figure. The report states, in conclusion, that in all probability in next year's accounts there will be shown revenue for the supply of electric energy to the tramway department.

**Bury.**—The annual report of the borough electricity engineer (Mr. S. J. Watson) shows that the number of consumers and lamps connected on March 31 was 420, with 44,199 candle-power lamps. The units sold during the past three years ending March of the year named are as follows:

| | 1903. | 1904. | 1905. |
|---|---|---|---|
| Private lighting | 228,288 | 250,301 | 297,202 |
| Public ,, | 55,582 | 54,664 | 61,887 |
| Public clock | — | 778 | 914 |
| Motors and heating | 141,123 | 299,538 | 258,208 |
| | 424,993 | 605,281 | 618,211 |
| Tramways | — | 67,630 | 662,250 |
| | 424,993 | 672,911 | 1,280,461 |
| Maximum load, kilowatts | 319·7 | 487·3 | 1,158 |
| Load factor | 15·17% | 15·7% | 12·6% |

Compared with the previous year, the output for private lighting shows an increase of 46,901 units, or 18·7 per cent.; public lighting an increase of 7,223 units, or 13·2 per cent.; public clock an increase of 136 units, or 17·5 per cent.; and motors and heating a decrease of 41,330 units, equal to 13·8 per cent. Excluding tramway supply, the increase is 12,930 units, equal to 2·1 per cent. Including tramway supply, the increase is 607,550 units, equal to 90 per cent. The decrease in the units sold for motors and heating is entirely due to the partial disuse of the motors used with the ice-making plant at the abattoirs, the units during the year having been 30,856, compared with 87,833 for the previous year, a decrease of 56,997 units. The output for different purposes, with the corresponding maximum load and load factor, is as follows:

| | Units. | Maximum load. | Load factor. |
|---|---|---|---|
| Lighting | 297,202 | 310 kw. | 11·0% |
| Public lamps | 62,801 | 21 kw. | 34·2% |
| Motors and heat | 258,208 | 112 kw. | 26·3% |
| Total light and power | 618,211 | 443 kw. | 15·9% |
| Tramways | 662,250 | 715 kw. | 10·6% |
| | 1,280,461 | 1,158 kw. | 12·6% |

The load factor for lighting and power, which stands at 15·9 per cent., indicates that the maximum load has been used for an average of 3 hours 49 minutes a day, compared with 4 hours 9½ minutes for the previous year, when the load factor was 17·3 per cent. The reduction is due to the decrease in the units sold for power purposes. The comparatively low load factor of the tramway supply has been partly caused through the system not having been completed and opened until September, and also on account of the abnormal loads put upon the generating plant when the special traffic is being dealt with in connection with football matches. Thirty-six arc lamps are in use for lighting the main streets of the borough, one additional lamp having been fixed in the middle of the Market-place and one by the parish church. To reduce the number of obstructions to traffic on the footpaths, it was decided to transfer 14 of the cast-iron pillars to adjacent tramway poles. This work was carried out, and the cost equally divided between the Electricity, Lighting, Sewering and Paving, and Tramway Committees. Eighteen incandescent fittings, each consisting of two 16 c.p. lamps, are in use in Spring-street and Heywood-street. Further progress has been made in the use of motors for driving small workshops. During the year 15 motors, equal to 101 h.p., have been hired out, and three motors, equal to 18 h.p., have been put in by consumers at their own cost. One motor of 8 h.p. belonging to a consumer has been disconnected. There are now 61 hired motors in use, amounting to 381 h.p., and 38 motors owned by consumers of 200 h.p., giving a total number connected of 99 motors, equal to 581 h.p. The total motors connected up to March, 1905, number 99. The length of street mains laid equal 15 miles 846 yards. The following analysis of costs is given: Total cost to March, 1903, £5,986, per unit 3·38; to March, 1904, £7,357, per unit 2·62; to March, 1905, £8,240, per unit 1·54. Profit to March, 1903, £21, per unit 01; to March, 1904, £566, per unit ·20; to March, 1905, £2,931, per unit ·55. Average price obtained to March, 1903, £6,007, per unit 3·39; to March, 1904, £7,923, per unit 2·82; to March, 1905, £11,171, per unit 2·09. The quantity of fuel used per unit sold has been reduced 26½ per cent. The average price has been 6s. 5d. per ton, compared with 6s. 6½d. per ton for the previous year. The cost of generating has been reduced by ·47d., equal to 36 per cent., and the total costs by 1·08d., equal to 41 per cent. per unit sold. The average price obtained has been less by ·73d. per unit, a reduction of 26 per cent. on the price for the previous year. The revenue for the year has increased by £3,248, or 41 per cent., and the generating costs by £777, or 21 per cent. The gross profit is £6,740, equal to 9 per cent. on the average capital employed, compared with £4,270, or 6¼ per cent. for the previous year. The net profit, after payment of all charges, is £2,931, equal to nearly 4 per cent. on the capital, compared with less than 1 per cent. for the previous year. An expenditure of £4,064 has been made on capital account, principally on new mains and services, motors for hiring, and balances on account of contracts for new generating plant. The total outlay is now £77,553. The alteration in the charges made from July 1 last has reduced the average price obtained from private lighting from 4·73d. to 4·17d. per unit sold, equal to 12 per cent.; for motor

Digitized by Google

power the reduction is from 1·54d. to 1·44d. per unit, equal to 6½ per cent.; and for public lighting from 2·14d. to 1·87d. per unit. During the present year there will be an increase in tramway consumption of nearly 250,000 units, and applications are in hand for the supply to 150 h.p. of motors, which will use at least 125,000 units per annum.

## PROVISIONAL PATENTS, 1905.

MAY 22.

2310A. **Improvements in electric switches.** Wallace Fairweather, 65, Chancery-lane, London. (The National Electric Company, United States.) (Date applied for under Patents Rule 9, Feb. 6, 1905. (Complete specification.)

10629. **A new or improved system or apparatus for automatically releasing electric telegraphs.** Eugène Ducretet, 77, Colmore-row, Birmingham. (Complete specification.)

10639. **Improvements in apparatus for use in regulating the load on direct-current electrical generators.** Ernest Sherwood Woollard Moore and William Guthrie Strang, Prince's-chambers, Wolverhampton.

10644. **Improvements in or connected with automatic electromagnetic sanding gear, for use on electric railway and tramway vehicles.** Mark Cummins, 8, Peel-terrace, Chester-road, Old Trafford, Manchester.

10647. **Improvements in telephones.** Percy Adolphus Vaile, 3, Whitehall-court, Westminster, London.

10653. **Improvements in vapour electric apparatus.** Percy Holbrook Thomas, the Westinghouse Patent Bureau, Westinghouse Building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, May 25, 1904, being date of application in United States.) (Complete specification.)

10669. **Improvements in combined electric switches and fuses.** Callender's Cable and Construction Company, Limited, and John Charles Augustus Ward, 24, Southampton-buildings, Chancery-lane, London. (Complete specification.)

10694. **New or improved means for neutralising static electricity.** William Henry Chapman, 18, Buckingham-street, Strand, London. (Complete specification.)

10695. **New or improved apparatus for neutralising static electricity.** William Henry Chapman, 18, Buckingham-street, Strand, London. (Complete specification.)

10696. **A new or improved apparatus for neutralising static electricity.** William Henry Chapman, 18, Buckingham-street, Strand, London. (Complete specification.)

10707. **Improvements relating to switching devices for use in electric flash advertising.** Leonard Kingwill Job, 322, High Holborn, London.

10708. **Improvements in receivers for wireless telegraphy.** William Phillips Thompson, 6, Lord-street, Liverpool. (Ges. für drahtlose Telegraphie m. b. H., Germany.) (Complete specification.)

10709. **Improvements in receiver connections for wireless telegraphy.** William Phillips Thompson, 6, Lord-street, Liverpool. (Ges. für drahtlose Telegraphie m. b. H., Germany.) (Complete specification.)

10710. **Improvements in transmitters for wireless telegraphy.** William Phillips Thompson, 6, Lord-street, Liverpool. (Ges. für drahtlose Telegraphie m. b. H., Germany.) (Complete specification.)

MAY 23.

10728. **Improvements in suspension devices for electric arc lamps.** Adolph Wunderlich and Gwylim Anwyl Hughes, trading as the London Electric Firm, 18, Southampton-buildings, Chancery-lane, London.

10793. **Improvements in electrical signalling apparatus.** Leon Byron Woodworth, 4, South-street, Finsbury, London.

10794. **Improvements in electrical signalling apparatus.** Leon Byron Woodworth, 4, South-street, Finsbury, London.

MAY 24.

10816. **Improvements in and relating to clutch mechanism for detachably connecting an arc lamp, or other appliance or apparatus, to a post, pillar, or other high-up support at a point out of reach.** Verity's Limited and Frederic Stanhope Worsley, 11, Burlington-chambers, New-street, Birmingham.

10818. **Improvements relating to self-contained travelling cranes with oil, gas, and electric motors and dynamos.** William Gordon Potter, 13, Mostyn-road, Brixton, London.

10819. **Improvements in and relating to apparatus for determining the presence and nature of electric currents in a circuit and for ascertaining the voltage of such currents.** Frederick Henry Varley, 57, Chancery-lane, London.

10828. **An improved overhead travelling hoist or "jenny" for electric or other power.** Ashley Crosthwaite Peake and John Robinson Crosthwaite, 6, Finkle-street, Stockton-on-Tees. (Complete specification.)

10888. **Improvements in or relating to primary batteries.** Kenneth Costley White and Joseph Cowley, Birkbeck Bank-chambers, Chancery-lane, London.

10830. **Improvements in apparatus for starting and for regulating the speed of compensated single-phase electric motors.** Engelbert Arnold and Jens Lassen La Cour, 34, Castle-street, Liverpool. (Date applied for under Patents Act, 1901, May 24, 1904, being date of application in Germany.) (Complete specification.)

10887. **Improvements relating to magneto-ignition devices of internal-combustion engines.** Stephen Dewar Holden and Frederick Vernon Russell, 8, Quality-court, Chancery-lane, London.

10892. **Improvements in systems of electric motor control and apparatus therefor.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

10893. **Improvements in and relating to systems of electric motor control and in apparatus therefor.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

10895. **Improvements in and relating to electric motor control systems and in apparatus therefor.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

10896. **Improvements in and relating to systems of electric motor control and in apparatus therefor.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

10897. **Improvements in and relating to dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

MAY 25.

10910. **Improvements in or relating to electrical switches.** William Herbert Isherwood, Carlton Mills, Woodhouse-lane, Leeds.

10928. **Improvements in fan ventilators.** Crompton and Co., Limited, and Claud Crompton, Arc Works, Chelmsford.

10949. **Improvements in insulation for commutators.** Max Meirowsky, 65, Chancery-lane, London.

10959. **Improvements relating to electrical measuring instruments.** Harry Hertzberg, William Prescott Snyder, James Henry Griffin, and Harry Irvin Bernhard, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

10970. **Improvements in or connected with insulated electric wires.** Walter Osmond, 40, Chancery-lane, London.

10973. **Improvements in terminals for electrical apparatus.** Harold William Smith, 322, High Holborn, London.

MAY 26.

11012. **Improvements in terminal clips for electric cables.** Mortimer Arthur Codd, 167, Oakwood-court, Addison-road, London.

11036. **Improvements in alternating-current measuring instruments.** Frank Conrad and William Maple Bradshaw, Westinghouse Patent Bureau, Westinghouse Building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, May 27, 1904, being date of application in United States.) (Complete specification.)

11040. **Improvements in electric batteries.** Dyson Fuller, 33, Chancery-lane, London.

11056. **Improvements in and connected with electric accumulator plates.** Henry Fairbrother, 33, Cannon-street, London.

11057. **Improved means applicable for use in transmitting and receiving communications by wireless telegraphy.** John Groeme Balsillie, Clun House, Surrey-street, London.

11061. **Improvements in brush-holders for dynamo-electric machines and the like.** Charles William Speirs and Julius Frith, 4, South-street, Finsbury, London.

11074. **Improvements in and relating to the regulation of the voltage of alternating-current systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

11075. **Improvements in electric heaters.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

11076. **Improvements in brush-holders for dynamos and motors.** Henry Francis Joel, sen., 74, Windsor-road, Forest Gate, Essex.

MAY 27.

11082. **An improved means of speed control and voltage regulation for electric motors and dynamos.** William Arthur Stevens, Victoria Works, St. Peter-street, Maidstone.

11120. **Improved system of electric wiring for electric lighting and power installations.** Herbert James Read, Chalford, Stanhope-road, St. Albans, Herts.

11142. **Improvements in insulating tapes.** Callender's Cable and Construction Company, Limited, and George Barnard, 24, Southampton-buildings, Chancery-lane, London.

11146. **Improvements in the manufacture of electrical resistances.** The Electric Equipment and Securities, Limited, and Charles Ruzicka, Clun House, Surrey-street, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published June 15.*

1904.

**6959A. Form of carbon specially suitable for filaments of electric incandescent lamps and the manufacture thereof.** Levis. (General Electric Company.) (Date applied for under Patents Rule 9, March 22, 1904.)

**11522. Commutator brushes.** Morgan Crucible Company, Limited, and Speirs.

**11884. Safety device for overhead electric conductors.** Hayward and Fox.

**11887. Rotary electric switch.** Dugdill.

**12545. Alternating-current electric meters.** Allgemeine Elektricitäts-Ges. (Date applied for under International Convention, June 2, 1903.)

**13353. Electrically-propelled railway and tramway vehicles.** Colling.

**13570. Controlling switches for electric circuits.** British Thomas-Houston Company, Limited. (General Electric Company.)

**13736. Apparatus employed for measuring wave lengths in wireless telegraphy.** Fleming.

**14111. Self-locking electric contact maker or switch for fire-alarm and other purposes.** Golding.

**14195. Electric tramways worked on the conduit system.** Watkins.

**14250. Dynamo-electric machines and the like.** Torda.

**14717. Insulating electric conductors especially suitable for the firing plugs of internal-combustion engines.** Leighton and Hacking.

**15070. Control of electric motors and machines driven thereby.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15303. Enclosed electric fuses.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15495. Dynamo-electric machines for regulating the charge and discharge of storage batteries used in combination with main generators.** Lancashire Dynamo and Motor Company, Limited, and McLeod.

**15648. Electrical resistances.** Veritys Limited and Gott.

**15879. Alternating electric current meters.** Allgemeine Elektricitäts-Ges. (Date applied for under International Convention, July 17, 1903.)

**16026. Vapour electric apparatus.** Carolan. (General Electric Company.)

**16109. Reverse electric current switches or circuit breakers.** British Thomson-Houston Company, Limited. (General Electric Company.)

**16241. Electric arc lamps.** Brockie.

**16260. Electric controllers.** British Thomson-Houston Company, Limited. (General Electric Company.)

**16409. Electric measuring instruments.** British Thomson-Houston Company, Limited. (General Electric Company.)

**17133 Electric governor for internal-combustion engines.** Roberts.

**29125. Switching devices for electric lamps especially adapted for use in "flash" advertising.** Job.

1905.

**392. Controlling the luminosity of electric lamps and their consumption of electric current.** Hunter.

**1231. Apparatus for operating gas taps and electrically igniting the gas.** Lorrain. (Soc. Anon. des Allumeurs-extincteurs Automatiques.)

**2632. Burnishing tools for use in the electro-deposition of metals.** Jobling and Harrison.

**2982. Line selectors for telephone and like systems.** Hardegen.

**5836. Electric glow lamps.** Scholvien. (Date applied for under International Convention, Sept. 29, 1904.)

**7295. Alternating-current electric motors.** Lamme. (Date applied for under International Convention, May 3, 1904.)

## NOTES.

**King's College.**—The forty-fifth annual dinner of this college will be held at the Hotel Cecil on Monday, the 26th inst., with Col. Richard H. Jelf, C.M.G., in the chair.

**Municipal and County Club.**—This club will entertain Mr. W. H. Grenfell, M.P., chairman of the Thames Conservancy Board, as their guest at the house dinner on the 29th inst.

**Wireless Telegraphy.**—It is reported that the Cunard liner "Campania" has been in continuous wireless communication with land throughout her voyage from Liverpool to New York. In mid-ocean she had simultaneous communication with America and Europe.

**Royal Institution.**—A general monthly meeting of the members of this institution was held on the 5th inst., the Duke of Northumberland, K.G., F.R.S., president, in the chair. Mr. E. Hurry Fenwick, F.R.C.S., and Mr. Oswald Lewis were elected members. The special thanks of the members were returned to Mr. L. F. Everest for his present of a portrait of Colonel Sir George Everest, C B., F.R.S.

**North-East Coast Institution.**—The issue dated May of the *Transactions* of the North-East Coast Institution of Engineers and Shipbuilders contains the Board of Trade regulations for certificated marine engineers, the resumed discussion on Mr. Frank Little's paper on "Petrol Motorcars," and the resumed discussion on Mr. J. F. C. Snell's paper on "The Application of Electricity to Industrial Purposes."

**The American Institute.**—The *Proceedings* of the American Institute for May contains Mr. G. F. Chellis's paper on "Time-Limit Relays"; Mr. H. W. Buck's paper on "Duplication of Electrical Apparatus to Secure Reliability of Service"; and Mr. Thorburn Reed's paper on "Limits of Injurious Sparking in Direct-Current Commutation," with the discussion on "Line Construction for High-Pressure Electric Railroads" and "High-Pressure Line Construction for Alternating-Current Railways." We learn, by the way, that Dr. S. S. Wheeler, whose career we briefly described in a recent issue, has been elected president for the ensuing year.

**Rose Polytechnic.**—We have received the twenty-third annual programme of this institution, which is situated at Terre Haute, Ind. The foundation provides higher education in engineering, its course of instruction embracing civil, electrical, and mechanical engineering and cognate subjects. The system in vogue is a judicious blending of laboratory work with lectures. There is an excellent library, over 10,000 volumes and 2,000 pamphlets being included, and additions are constantly being made. The students of all grades total 219. There is an extensive staff of instructors, and we infer that the institution is performing good work in the American engineering field.

**Electricity for Training Horses.**—The *Swiss Artillery and Engineers' Review* describes the use of electricity in training horses at the depôt of remounts for the Swiss cavalry. The electric shock is used as a corrective, the apparatus employed being a battery and circuit. The battery is contained in a little leather case, which the officer carries on his shoulder, and a special system permits him to localise the effect of the discharge at any particular part of the horse's body. Although the current generated by the battery is very weak, it produces upon the horse a remarkable and enduring effect, which, it is claimed, enables a bad habit to be speedily overcome. Several successful applications of the kind are reported, and in no case has the use of electricity proved injurious.

**Attracting Traffic.**—The American's penchant for advertising is well known, and, despite the dictum that there is nothing new under the sun, he often contrives to achieve novelty. The Rochester and Sodus Bay Railway, U.S.A., is an interurban line of 40 miles which traverses territory rich in fruit and flowers. When May comes round and the apple blossoms are in their glory, the line is advertised as the "Apple Blossom Route—40 miles of Apple Blossoms," etc. A car with accommodation for 40 to 50 people can be chartered for this trip at the rate of £10, or single daily excursion tickets can be had for 3s. In the case of private parties souvenir cards, decorated with apple blossoms and containing an alluring invitation to see the real thing, are sometimes issued. Enterprise of this sort would probably be advantageous to the lines of this country.

**The Institution.**—The issue of the *Journal* dated May contains Mr. G. L. Addenbrooke's paper on "The Value of Overhead Mains for Electric Distribution in the United Kingdom," with the discussion; Mr. Donald Murray's paper on "Setting Type by Telegraph," with the discussion; Mr. E. H. Rayner's paper comprising a report on temperature experiments carried out at the National Physical Laboratory; and Mr. R. Goldschmidt's paper on "Temperature Curves and the Rating of Electrical Machinery," with the joint discussion; Mr. H. B. Maxwell's paper before the Glasgow Section on "Street-Lighting by Electric Arc Lamps," with the discussion; Mr. H. W. Wilson's paper on "The Electrical Operation of Textile Factories" (Manchester Section); and Mr. J. Lord's paper on "Tramways Permanent-Way Construction and Maintenance." In future the *Journal* will consist of two volumes annually instead of one.

**Electric Furnaces.**—We have received from the publisher, Mr. A. Hermann, of 6-12, Rue de la Sorbonne, Paris, an interesting book entitled "Le Four Electrique," which relates to the origin, transformations, and applications of electric furnaces, and is from the pen of M. Adolphe Minet. The volume in question contains portraits of eight of the pioneers in electro-metallurgy and a large number of illustrations. The development of the electric furnace is traced from the earliest laboratory experiments, and a large number of furnaces are described which have not actually led to commercial results. The volume is a useful one as a book of reference, and we think that it would be rendered more valuable if further details of the actual results obtained in the most modern commercial undertakings were given. The last part of the book deals with the theory of the subject, and is useful to the electrical engineer entering this department of the profession.

**Motor 'Buses.**—The North-Eastern Railway Company scored a success in the House of Commons last week, when their Bill authorising the running of motor 'buses was ordered for third reading. An amendment designed to prevent the vehicles from taking up passengers at intermediate points between stations was rejected, so that the efforts of the Municipal Tramways Association were unavailing on this occasion. The remarks of Mr. Bonar Law are interesting, as reflecting the views of the Board of Trade. He stated that it would be a disastrous thing to pass the amendment. The "drum municipal" had been beaten again. They were told that this traffic would injure tramways, but when it was proposed to bring a tramway over Westminster Bridge it was said that motor 'buses could not compete with tramcars. The Board of Trade had constantly to see that the railway companies carried out the obligations imposed on them by Parliament, and the Board were bound to use its influence to prevent the companies from being unfairly treated. It was becoming a question of whether Parlia-

Digitized by Google

ment was to control the municipalities or whether they were to control Parliament.

**Electricity in Mining.**—We observe from the annual report of the Tredegar Iron and Coal Company, Limited, that, despite unusual conditions of an adverse character, the company maintained practically continuous working, with the result that the directors are able to recommend a dividend of 5 per cent., after placing £25,300 to capital account and carrying forward £1,353. The output of coal aggregated 1,421,230 tons. Of special interest to electrical engineers, however, is the circumstance that the electrical plant, the installation of which was commenced about four years ago, has now been working in its entirety for a sufficient period to enable the directors to state, after exhaustive tests and minute enquiry and comparisons, that the results fully justify the expenditure in adopting electricity as the motive power for hauling, pumping, and lighting the collieries. With such definite results as this to guide them, there should be a distinct impetus to the employment of electricity on the part of colliery owners.

**Copper Production.**—From an approximate report upon the world's copper production, it appears that the total for 1904 was about 632,166 metric tons, against 578,876 for 1903. The United States easily heads the list with 349,866 tons, Mexico being second with the comparatively modest record of 52,500 tons. Spain and Portugal constitute the most prolific of the European representatives with 50,000 tons. Germany is credited with 30,000 tons, and Russia with 10,000. The output of the other European countries is insignificant, Great Britain being deemed unworthy of mention. The world's copper production has risen progressively during the past century from 91,000 tons for the decade 1801-10 to the 632,166 recorded for 1904. Spain, which 25 years ago ranked first among the nations as a copper-producing country, now takes third place. Japan turned out 32,000 during the past year, and Australia and Canada are credited with the respectable records of 30,000 and 21,500 tons.

**Association of Municipal and County Engineers** The annual meeting of the members of the western district of the above association was held at Gloucester on Saturday, when, after a reception by members of the Corporation, the party, to the number of about 75, were conveyed by special trams to the works and new offices of the Gloucester Railway Carriage and Wagon Company, through the many departments of which they were shown by Mr. B. Allen, assistant manager, and other officials. Thence they journeyed to the municipal depôt and the electric depôt. After lunch the party inspected the Corporation electric light and power station under the guidance of Mr. W. Bache. Later in the afternoon the annual meeting was held at the Guildhall. Mr. Pickering was unanimously re-elected hon. secretary of the western district, and two papers, the first by Mr. R. Read on "The Municipal Works of the City," and the second by Mr. W. Bache, electrical engineer, on "Gloucester Electricity Works," were discussed. The papers are reproduced elsewhere in this issue.

**Board of Trade Organisation.**—A discussion took place in the House of Commons on Tuesday as to the reorganisation of the Board of Trade. Sir Albert Rollit drew attention to the urgent desirability of the appointment of a minister of commerce and industry if we desired to maintain our commercial pre-eminence. Mr. Bonar Law, permanent secretary to the Board, recognised that the feeling of the House was unanimous in favour of some change in the constitution of the Board, and stated that a Bill had been drafted in order to carry out the promise contained in the King's Speech. He concurred in the desirability of bringing the Department into closer touch with men engaged in commerce, and thought it could be best done through the agency of the Commercial Intelligence Department. There were, however, difficulties in the way in connection with getting permanent officials to run in harness with outsiders, and in preventing the Department from entering upon thorny controversial ground. He could not promise action with regard to differential railway rates, pending the report of the committee now considering the subject.

**Electricity in Egypt.**—The *Bulletin* of the French Chamber of Commerce on electricity contains an interesting article and analyses of the various applications of electricity which are possible in Egypt. This points out in the first instance that agriculture and irrigation are the principal operations carried on in Egypt, and that it is in irrigation that electricity is most likely to be of service. There are large numbers of small pumps now used for this purpose which could frequently be replaced by a smaller number of electrically-driven pumps. These could be supplied with energy by means of overhead wires carried a considerable distance to the source of power. The report considers that in Upper Egypt this application of electricity will be found most useful, and that the Falls of the Nile should be used as a source of power. Information is also given as to the extent to which electricity is now used in the larger Egyptian towns, and in factories which have sprung up in the neighbourhood. For electrical purposes it is said that the oil-engine is a strong competitor with electricity in certain districts, owing to the cheapness of oil. After indicating a number of ways in which an extended use of electricity is to be looked for, the report concludes with a strong plea for better representation of French firms in the country.

**Inductance in Telephone Circuits.**—When inductance coils are introduced at regular intervals through a telephone cable, the electrostatic capacity is neutralised by sections, but the conductors of sections between the inductance coils are free from any characteristic tending to counteract the electrostatic condition that may arise between the inductance coils. Prof. D. C. Jackson, according to a patent recently issued to him in the United States, and described in the *Electrical World*, proposes to form the conductor which is to carry the current in a helix

to create inductance, this helical formation being practically continuous throughout the entire circuit. The core for the helix may be of air, or magnetic material may be used for this purpose. The accompanying diagram illustrates a grounded telephone circuit, the major portion of its metallic part being in the form of an inductance helix. On the assumption that the highest voice harmonic which must be preserved for satisfactory telephonic transmission has a frequency of 1,000 periods per second, the inventor develops formulæ for determining the amount of inductance necessary to neutralise any given amount of electrostatic capacity.

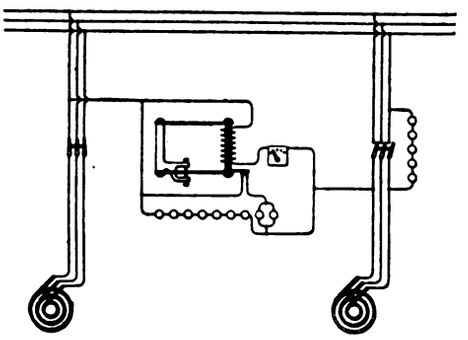
**Electricity in India.**—Licenses have been granted by the municipalities of Delhi and Lahore to Messrs. Arthur Grey, Thomas Wilson, and L. R. Windham-Forrest for electric lighting and tramway schemes in the respective cities. The Delhi scheme provides for a low-tension con-

Digitized by Google

tinuous current, a separate distributing system being employed for the tramways, with the return circuit through the rails. Energy will be supplied to the car motors at 500 volts. For lighting, current is to be generated at 500 to 550 volts, and distributed by a three-wire system with 250 volts difference of potential between the neutral and outer wires at the consumer's premises. Regarding the tramways, the licensees shall commence the construction of same within two years, and shall complete same "with all reasonable speed." Exemption from wheel-tax on all vehicles to be used on the track, and from octroi on all plant, machinery, rolling-stock, and other materials imported during the first two years, is accorded to the licensees. The municipality is to receive a yearly rent of Rs.800 per mile of double track and Rs.500 per mile of single track, such rent not to begin until the net profits shall have reached 6 per cent. per annum. The license provides that the charge to consumers of current for lighting shall not exceed Rs.20 for any quantity up to 20 units, or 10 annas for each unit over 20. A low-tension continuous-current system, with a three-wire distribution for lighting, will likewise be employed at Lahore. Slightly lower voltages will be generated both for lighting and traction. Similar exemptions regarding wheel-tax and octroi are granted, and the clauses in the license concerning the charges on the tramway and the tariff for lighting are identical with those in the case of Delhi.

**Indiarubber.**—The *Bulletin*, just issued, of the Imperial Institute contains two interesting reports on samples of indiarubber received from Rhodesia. The first of these was obtained from the "Muteke" plant, which, the report states, is a large creeper, its stem reaching to 1ft. in diameter. It is said to be common all over the Abercorn division of North-Eastern Rhodesia. The samples of the rubber sent to the institute were collected by the administrator of the district, but, unfortunately, the quantity was not sufficient to enable full information of the commercial value of the rubber to be obtained. Two samples were submitted, one obtained from the stem of the creeper and the other from the root It appears that the stem contains considerably more rubber than the root. From the specimens of the leaves, flowers, and fruit of the creeper submitted to the Kew Garden authorities, it appears that the Muteke plant is likely to prove to be an entirely new species of *Landolphia*. Analyses show that the rubber is of fair quality, though the amount of resin present is rather higher than is desirable. Larger samples are being asked for in order to ascertain the exact value of this rubber. In the other instance referred to the sample was of "Dande" rubber, obtained from the Umtali district of Rhodesia. Analyses show that this contains 80·7 per cent. of caoutchouc and 12·6 per cent. of resin when dry. The sample as received contained, however, some 15·5 per cent. of moisture. The commercial value of the rubber was ascertained to be about 3s. 6d. per pound. It seems clear, from the results obtained, that the "Dande" plant yields a marketable rubber of good value, and, if the plant is abundant in Rhodesia, it should prove a valuable source of that material. The exact order of the plant could not be determined at Kew, as insufficient means of identification accompanied the sample.

**Synchronism Indicator.**—A patent has been granted in the United States to Mr. P. L. Clark, of Chicago, for a synchronism indicator, which he has assigned to the General Electric Company. The invention, which is briefly described in the *Electrical Review* of New York, relates to devices for indicating the proper instant for closing the line switch of an alternating-current generator, synchronous motor, or rotary converter which is to be connected in parallel with another similar machine already in operation. It is understood that this is to be done when the machines are in step, it being uncertain under ordinary conditions when this instant occurs. The machines are never thrown together when the indicating lamps are fluctuating with short beats, and as the beats grow longer the interval of darkness or brightness extends over so long a period that it is difficult to guess just the right instant to close the switch. This invention aims to eliminate any possible doubt on this score, and it consists of a signalling device, such as an indicating lamp controlled by a switch, which is kept open so long as the phase displacement is at a maximum and is closed by a solenoid only when the beats become very long,



and at the middle portion only of each beat. The connections of this device are shown in the illustration.

**Rural Railway Lines.**—Before the Chicago branch of the American Institute of Electrical Engineers, Mr. J. R. Cravath recently read an interesting paper, entitled "Light Electric Railways." The paper was designed to show that by modifying the type of construction, many rural districts now unserved from financial considerations might be made to yield a fair profit. Approximately the cost of the typical interurban electric railways of the Central Western States is £4,500 per mile of single track, requiring for financial success a gross revenue of £600 to £800 per track mile per annum. The author outlined a narrow-gauge system, suggesting a gauge of 28in. and the use of 30lb. T-rails. An estimate in detail is given of the cost per mile of such a line and its equipment on the basis of a 15-mile road. Excluding expenditure for right-of-way, the total for the track is given at £870 per mile; for general roadway items, £60 per mile; overhead line, £178 per mile; rolling-stock, buildings, etc., £465 per mile, the total being £1,570 per mile of track. This provides for three passenger motorcars, two passenger trailers, one freight motorcar, and 15 miscellaneous freight car trailers. An estimate of the ordinary operating expenses per train mile of such a road is 4¼d. per train mile, and for a traffic of 135,000 train miles per year, including interest on cost of construction, the total annual charge would be £260 per track mile. The author gave an interesting analysis of rural passenger and freight traffic, upon which is based an estimate of the traffic possibilities of a strictly rural territory. Estimates were obtained from several farmers as to the amount of farm products consigned and supplies received. Upon these data it is estimated that the total freight revenue from an average rural district in the Central Western States would be about £16 per square mile. After discussing in detail the question of passenger traffic, Mr. Cravath considers that a total gross earning of £330 per track mile is possible. Subtracting the charges previously estimated, this would leave a surplus of £80 per track mile.

**Mining Engineers' Conference.**—The members of the Institution of Mining Engineers held their annual two days' session last week. Sympathetic reference to the decease of the president, Sir Lowthian Bell, was made

Digitized by Google

by Mr. H. C. Peake, one of the past-presidents. Three papers were read dealing with winding engines and gears, and a long discussion took place on the relative merits of steam and electric winding. Several speakers favoured the electric system in use in Germany and the North of France, but the majority appeared to think that the economies to be effected by electricity scarcely justified the large outlay on new electric plant. The view of the latter seemed to be that electric winding might do very well for the small and slow systems of the Continent, but the initial outlay would be enormous if electricity were applied to the deep shafts and rapid working in this country. Two interesting papers were presented dealing with mining education in America and New Zealand. Prof. Howard Eckfeldt, U.S.A., stated that there were about 45 schools in America which conferred the degree of "engineer of mining." Formerly the technical graduate was looked upon as being almost entirely useless to the industrial world, and at best was little better than the average labourer. He was classed as one who had his mind full of ideas and theories, which would not stand against the old cut-and-dried rules of years of practice. Now, however, when the mineral resources of the country were being exploited everywhere, nearly every State had its special school where men got a three or four years' training. In the vacations most of the students secured positions at practical work. Last year in some places a mine was loaned and worked by students, under the supervision of the teaching staff, and the practical results were highly satisfactory. Prof. James Park stated that six schools in the New Zealand goldfields are subsidised by the Government, and managed by councils elected by local subscribers. The schools are generally well attended, and have already exercised a marked influence in raising the general intelligence of the mining community. The combination of theory and practice in the schools has been attended by the most happy results.

**Scotch Water Power.**—The British Aluminium Company have this week offered to the public a further issue of shares, and a brief *résumé* of the work performed by them will be opportune. It was the first concern to put down an extensive water-power plant in the United Kingdom for electrometallurgical purposes. The company was formed in 1894, and the construction of the necessary works at Loch Ness was commenced early in 1895. An interesting feature in the working of the company is that it purchased a large estate, including the Falls of Foyer, and thus acquired water-power rights which might otherwise have been difficult to obtain. The works were so far completed that the production of aluminium was commenced towards the end of 1895. During the next few years the manufactory was continued upon a small scale, but a considerable amount of calcium carbide was turned out. In 1902, following a change of policy and considerable reduction in price, there was a great improvement, and since then there has been a steady increase in the tonnage sold. Owing to the expansion in sales, which still continues, the maximum capacity of output of the Foyers works is now inadequate to satisfy the demand for the company's metal, and consequently further water power is imperatively required. It has therefore been decided to exercise the powers secured by the company under the Loch Leven Water Power Act, 1901, and the Loch Leven Water Power Amendment Act, 1904, to carry out water-power works at the head of Loch Leven in Argyllshire. It is expected that some 12,000 h.p. to 15,000 h.p. can be developed there, which is approximately double the amount of power the company now has at Foyers. These Acts are held by the Loch Leven Water and Electric Power Company, the whole of whose issued capital, amounting to 4,000 shares of £10 each, is held by this company, which will also subscribe for a further 46,000 shares of £10 each, being all the shares it is at present intended to issue. It is believed that the amount thus furnished will suffice for the completion of the scheme. The progressive improvement in sales has produced a steady growth in the profits. The profit for the year 1904 was £55,411. 3s. 11d., an increase of £21,267. 18s. 1d. over that of 1903. Last December an extension of the Foyer water power was completed, and this year the output of aluminium will be much larger. The directors, therefore, confidently anticipate that the profits for the current year will be materially increased.

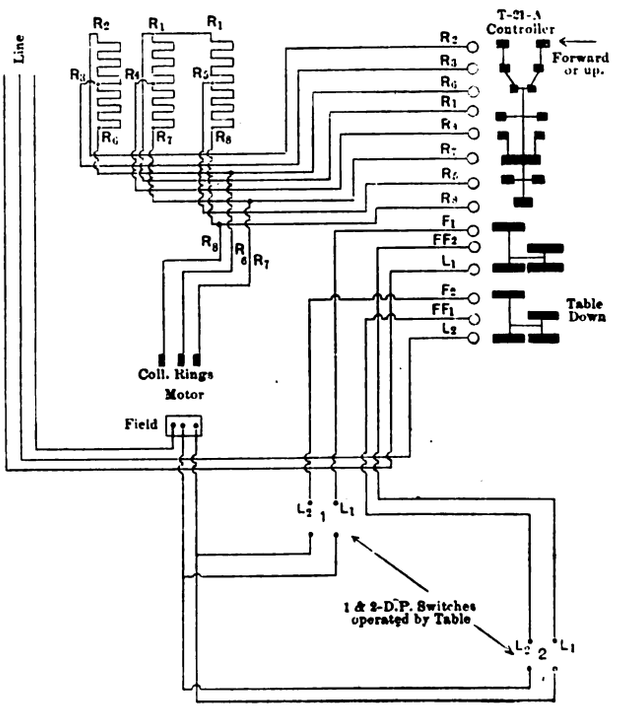
**Patents in 1904.**—The report of the Comptroller-General of Patents, Designs, and Trade Marks for 1904 states that the applications accompanied by complete specifications were more numerous than in any previous year, and exceeded the number received in 1903 by 602, an increase of 9·1 per cent. The applications received in 1904 numbered 29,678, as compared with 28,853 in 1903, an increase of 825, or 2·3 per cent. Of these applications 22,442 were accompanied by provisional specifications, and 7,236 by complete specifications. On the other hand, the number of complete specifications filed after provisional specification was only 8,684, as compared with 9,187, a decrease of 503. The total number of specifications was 38,362, as compared with 38,019, an increase of 343, or ·9 per cent. The most remarkable development is shown in the class rotary engines (including turbines), in which the general increase is 40 per cent., and the increase in turbines alone is more than double that amount. A marked growth appears also in the class air and gas engines, which has advanced to the extent of 27 per cent. The number of inventions relating to reciprocating steam-engines and to electric motors (class dynamo-electric generators, etc.) has also advanced, though to a less extent. The number of inventions for cycles continues to diminish, and is now less than one-fourth of the number for 1897, although the number of motor-cycles has increased 36 per cent. from the previous year, and is more than three times as many as in 1897. The number of wheels for vehicles has risen, although it is still only 40 per cent. of the number for 1897. Both road vehicles and railway and tramway vehicles have diminished, but locomotives, etc., have increased slightly, owing to the development of motorcars. About two-thirds of the whole number, and no less than 85 per cent. of the motor-cycles, are of British origin. The remarkable development of the motor vehicle industry in this country is shown by the fact that the total number of British inventions has doubled since 1900, when less than one-half of the whole and only a little more than one-half of the cycles were of British origin. The oil or gas engine type of motor finds most favour. Electricity receded as a medium of power for motorcars and cycles. The activity in the motorcar industry still continues. Though the number of applications pertaining to motorcars reached a maximum in the previous year, this number was almost reached in 1904, while in the details, such as wheels (including tyres), lamps, variable-speed gearing, and oil motors, the numbers of 1903 have been considerably exceeded. The attention that is being given in engineering circles to turbines is significantly illustrated by the fact that more applications for patents were made for this class of motor than for all classes of reciprocating steam-engines put together. The actual numbers under turbines show a considerable increase on those of 1903, while there is a corresponding decrease in the number of steam-engines and also of steam generators. The keenness of the competition

Digitized by Google

between gas and electricity as illuminants is vividly reflected by the figures for 1904. On the one hand, the number of applications bearing upon dynamos and both arc and incandescent electric lamps is greater than that for 1903, but there is at the same time a marked increase in the number relating to gas lamps and the manufacture and purification of gas. The subject of mercury vapour lamps, to which reference was made in the last annual report, has received increased attention during the year, especially from American inventors, but the inventions have been mainly directed towards the adaptation of such lamps to a variety of novel purposes other than lighting, such as switching, rectifying, controlling, and distributing electric currents.

**Moving Platform Subway.**—A description of the moving platform subway proposed to be constructed in New York City to provide additional means of transit across town is given in the *Scientific American*. It was originally proposed to have the subway below Thirty-fourth-street. The Rapid Transit Commission are apparently opposed to this, but are prepared to agree to the system being constructed below Twenty-third-street. The subway is planned to be divided into halves, the whole section of the tunnel to be 30ft. wide by 14ft. in height. The moving platform proper consists of three continuous lines of steel plate, covered with rubber to ensure a safe footing. The plates overlap laterally at their edges. The fourth platform is an auxiliary, which will be run at a speed of three miles an hour, and used only for a few hours after midnight, when travel is lightest, at which time the main moving platform will be stationary. The first moving platform will run at a constant speed of three miles an hour, the second at six miles, and the third platform at nine miles an hour. The first two platforms will be known as stepping platforms, and the third, which is considerably wider, will be provided with transverse seats. To assist passengers in moving from one platform to another, the two stepping platforms will be provided with lines of vertical posts, placed at frequent intervals. The platforms will be built in sections, each of which will be about 6ft. long, and the abutting ends of the sections will be struck to a radius which will permit of the platform curving around the terminal loops at First and Ninth avenues. Extending longitudinally beneath each platform is a pair of I-beams, the upper flanges of which are riveted to the bottom of the platform, while the lower flanges serve to support the weight of the platform upon pairs of wheels which are carried upon transverse shafts mounted at intervals of 2ft. 9in. upon concrete piers. Between each pair of longitudinal I-beams is carried a pair of horizontal guide wheels, which engage a guide rail that serves to keep the platform in proper alignment. At every 75ft. 10-h.p. motors are mounted on the floor of the subway, and are connected by a chain drive with the transverse shafts, which carry what might be called the driving wheels of the platform. The gradation in the rate of speed of the sections of the platform is secured by varying the diameter of these driving wheels, which are 8in. in diameter for the three-mile, 16in. in diameter for the six-mile, and 24in. in diameter for the nine-mile platform. The driving wheels are covered with rubber, as are the horizontal central guide wheels, and consequently the motion of the platform will be both smooth and silent. The successive sections of the platform are coupled together by means of links, 46in. in length, and the coupling pins are placed at the centre from which the curves of the abutting ends of the platform sections are struck; consequently, the opening between the joints may be reduced to a minimum, and a smooth and continuous surface presented for walking.

**Electrical Equipment of a Railway Shop.**—An interesting description appears in the *Electrical World* of the repair shop of the Great Northern Railway Company at St. Paul, U.S.A., which, unlike many such establishments, was initially designed for electrical driving on the three-phase system with General Electric induction motors. On account of their isolated position many of the machines were equipped with individual motors, but a general effort was made to use a single motor to drive groups of the smaller machines requiring frequent starting and stopping. The motors in these instances are placed overhead on the structures which support the line shafting. Many of the machines are directly geared to the motors. In other instances, however, the Renold chain drive is employed, and in some cases leather belting of the usual type is used. One of the chief features of interest in the plant is the successful operation of variable-speed induction motors. The cranes, transfer table, wheel lathes, and several other machines are driven by motors capable of speed variations. In one instance—that of a 96in. driving-wheel lathe—the controller is located within easy reach of the operator. In all the variable-speed installations the different speeds are obtained by inserting resistances in the secondary circuits.



The controller also permits of reversal of direction of rotation, this being accomplished by interchanging two of the three leads to the stator. In the case of the wheel lathe, the rheostats in connection with the control circuit are immediately behind the controller. These are provided with sufficient radiating surface to permit continuous operation of the motor at any speed without undue heating. Another special feature is the equipment used in connection with the drop-table in the machine shop. The 20-h.p. motor which operates the table is installed in an adjacent pit. The interesting point in regard to the electrical equipment is the arrangement by which the motor is stopped automatically when the table reaches certain limits of travel. When the motor is stopped by the device it cannot be started until reversed. The connections of the controller by which this is accomplished are shown in the accompanying diagram, which we reproduce from the *Electrical World* of New York. Lugs permanently attached to the moving table operate dogs which, in turn, open the switches. If the upper switch, shown in the diagram, be opened, the motor cannot be started through $F_1$ and $F_2$. To start it through $FF_1$ and $FF_2$ it is necessary to reverse the motor, which lowers the table.

## GLOUCESTER ELECTRICITY WORKS.*

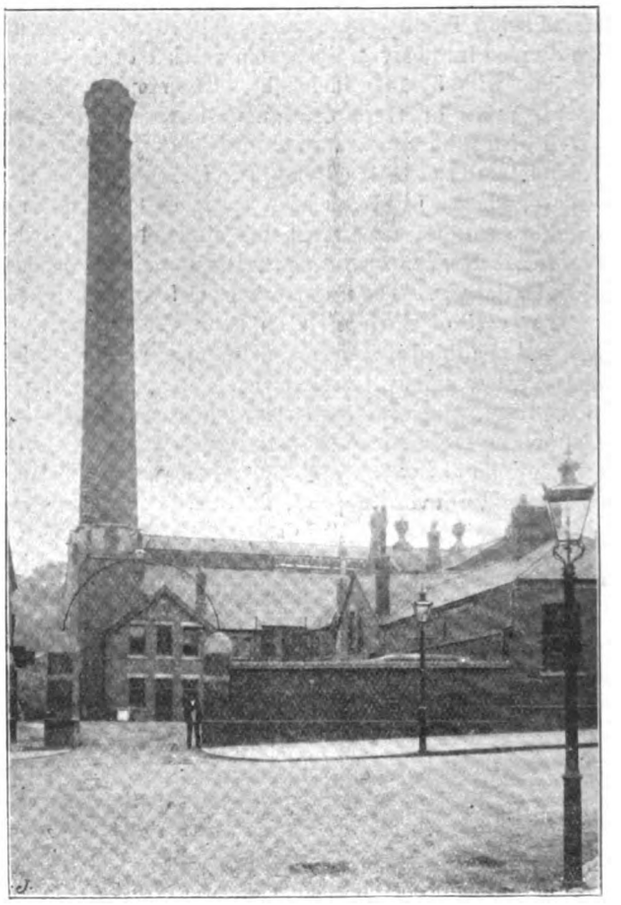
BY WALTER J. BACHE, M.I.E.E, ELECTRICAL ENGINEER.

The Gloucester municipal electricity works were authorised by a provisional order granted in 1896, in response to an application by the Corporation, who lost no time on the receipt of the order in taking steps to erect their works. In 1897 the Council instructed Mr. Robert Hammond to prepare a preliminary report, and in the following August they decided to establish electricity works in combination with a refuse destructor, on the lines advocated by Mr. Hammond, and instructed him to draw up a detailed scheme. It is interesting to note that the present arrangement of the works was designed eight years ago, and although this is a considerable period in the history of electricity supply, the works may be considered, even now, up-to-date and of modern design. It would not be difficult to find works designed later than 1897 of which the same could not be said at the present time. The scheme submitted provided for a three-wire, direct-current, low-tension system of generation and distribution, with Lancashire boilers, two generating sets, each consisting of two dynamos in tandem direct coupled to a high-speed engine, and a triple-concentric network fed at various points by triple-concentric feeders. The architect's work was placed in the hands of Mr. Harry A. Dancey, of Gloucester, who carried out the ideas of the engineer in a successful manner, and provided a very suitable and pleasing set of plans.

MR. W. J. BACHE, CITY ELECTRICAL ENGINEER, GLOUCESTER.

The combined electricity works and refuse destructor were designed as one scheme, but owing to delays in obtaining possession of the site, and other causes, the electricity works were running two years before the completion of the refuse destructor. The selection of a suitable site for the works demanded careful consideration from many points, as the conditions vary greatly as regards network in the residential and manufacturing parts of the same town. The general characteristics have to be reviewed, the location and probable lamp density of the more important areas of supply must be estimated, and the immediate vicinity of the suggested site must be examined in order to avoid placing the works where a nuisance may be created. Facilities for obtaining coal and water for condensing are essential to economical working, and require due consideration. The terms on which the site can be acquired, and the cost of rendering it suitable by excavation, removal of old buildings, etc., will also have a bearing on the choice of the site. All these considerations were carefully gone into in the Gloucester works, with the result that the site is particularly well chosen. The works are situated in the south-west part of the city, and are most conveniently placed, within 600 yards of the Cross, which is the business centre. They are also close to the docks, which afford an abundant supply of water for condensing purposes, while the railway lines in the docks provide connection with the Midland and Great Western Railways. At present there is no siding into the works, but should one be required in the future it could be laid down without any difficulty. The ground on which the buildings stand consists of "made soil," and during the excavations for the foundations many traces of the Roman occupation were brought to light. The foundations are carried down to the blue lias clay, which was found at a depth of 11ft. below the surface. Underneath the condenser pit the contractor encountered a portion of the old bed of the Severn, and two underground watercourses traverse the site diagonally from north-east to south-west, and are separated by a distance of about 30ft. to 40ft. A bed of quicksand in the boiler-house and a series of extraordinary pockets or depressions in the lias clay under the refuse destructor and the chimney stack added to the builder's difficulties, and called for special methods of construction.

The buildings are of brick with stone dressings, and consist of two large bays for the boiler-house and engine-room respectively, a small bay containing the test-room and switch-room with the battery-room over, and a well arranged suite of offices and stores. The refuse destructor is placed at a right angle to the boiler-house, and between the latter and the chimney stack. Provision has been made for the extension of the engine-room and boiler-house. The chimney stack is 150ft. high from the ground level. It rests upon a solid bed of concrete, 30ft. square and 10ft. deep. The brickwork footings are 6ft. deep. The chimney is built square for the first 37ft., and from this height to the top it is octagonal in shape. The internal diameter is 6ft. throughout, inside the firebrick lining, which is carried to a height of 60ft., with a 4½in. air space between the lining and the outer brickwork. The chimney has an ornamental moulded stone cap. The theoretical capacity of the chimney is approximately 1,100 h.p., and it accommodates six boilers at the present time, which, if all were steaming together, would exceed its full capacity. Three new Lancashire boilers are being laid down this year, and it is probable that when the next boiler extension is

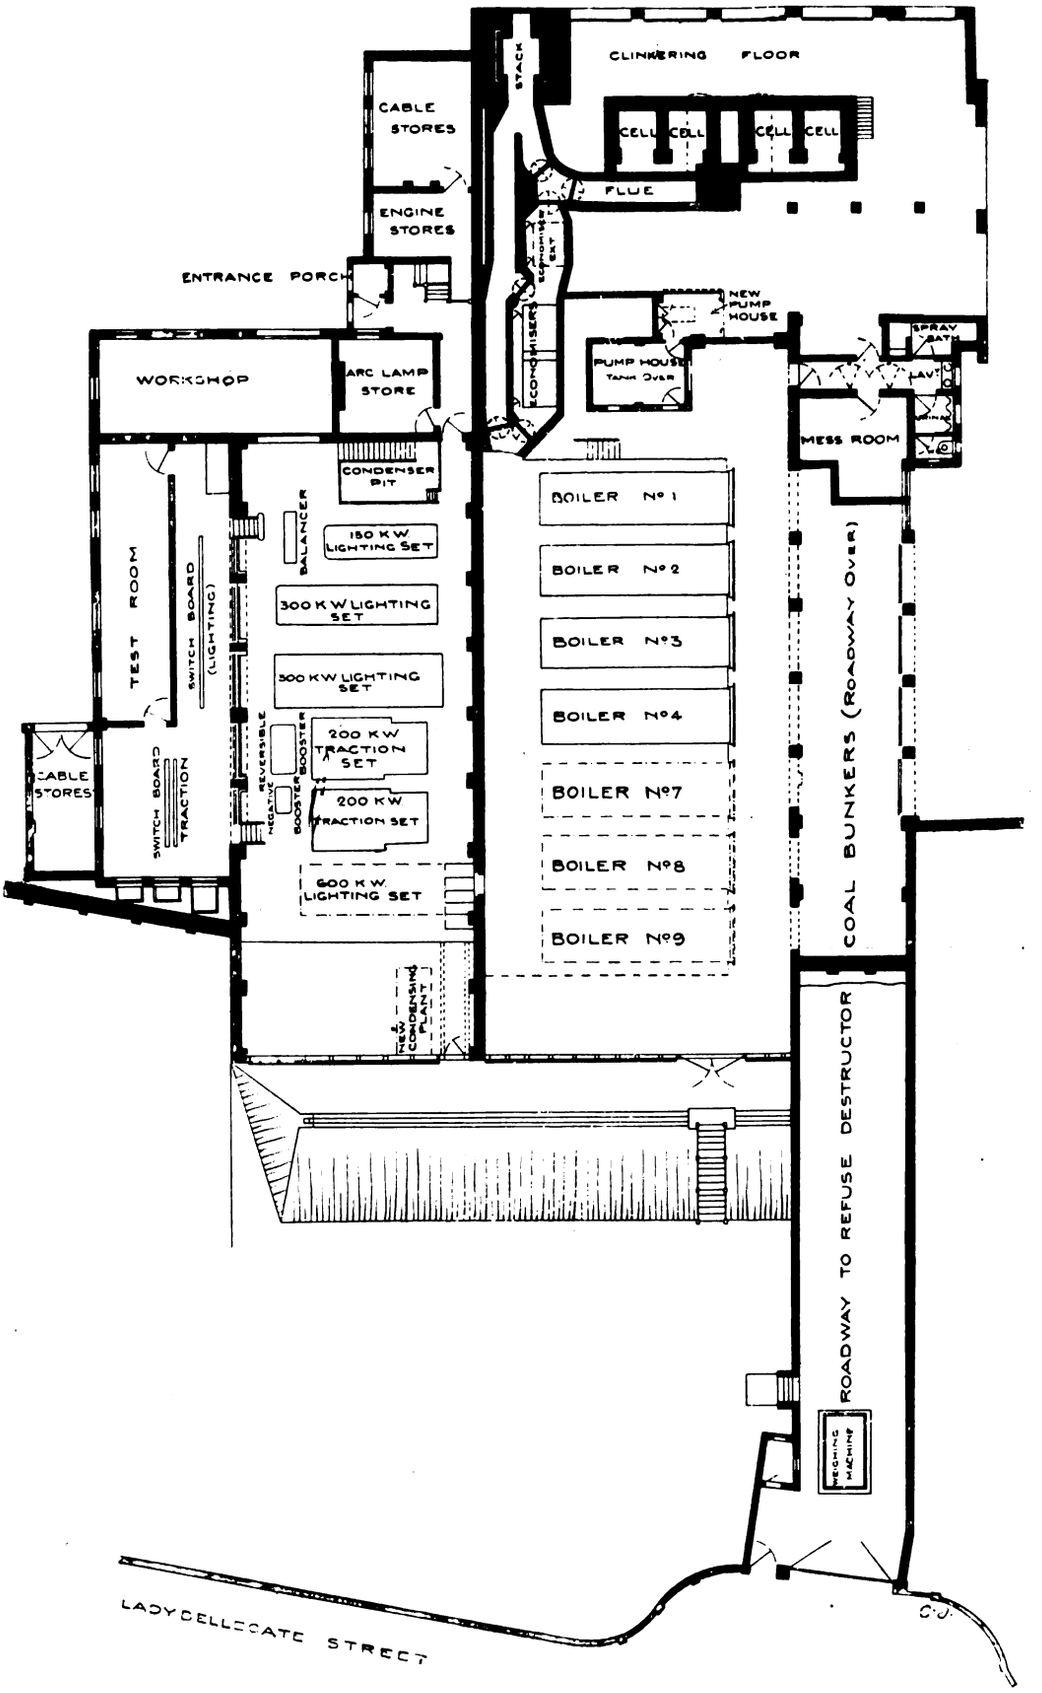


Main Entrance to Electricity Works, Gloucester.

* Paper read before the Western District meeting of the Incorporated Association of Municipal and County Engineers held at Gloucester on June 3.

Digitized by Google

made it will be necessary to provide for an increased draught. It is interesting here to compare the relative costs of the various methods of obtaining draught for boilers on the horse-power capacity basis as above stated. Taking first the cost of an ordinary brick chimney, of which Gloucester is a typical example, the price may be stated at £1,500. An Alphons Custodis chimney of the same capacity would cost about £900. Coming now to mechanical draught, and assuming that conditions similar to those in Gloucester have to be met, the capital outlay, including the necessary short steel stack, is only about £350. Forced draught has many advantages over induced draught, for the former has only to push the air through the fire, while induced draught has to do this and also to draw the products of combustion along the flues, and thus obviously requires more power. Further, the induced-draught fan has to deal with gases at a high temperature, and containing a good many destructive constituents. Therefore, its life must be considerably shorter. Again, the induced-draught fan sucks in cold air through every crack and crevice in the boiler setting and elsewhere. Forced draught, on the other hand, tends to seal up such cracks with flue dust, or make them permanently or aggressively visible by forcing smoke through them.

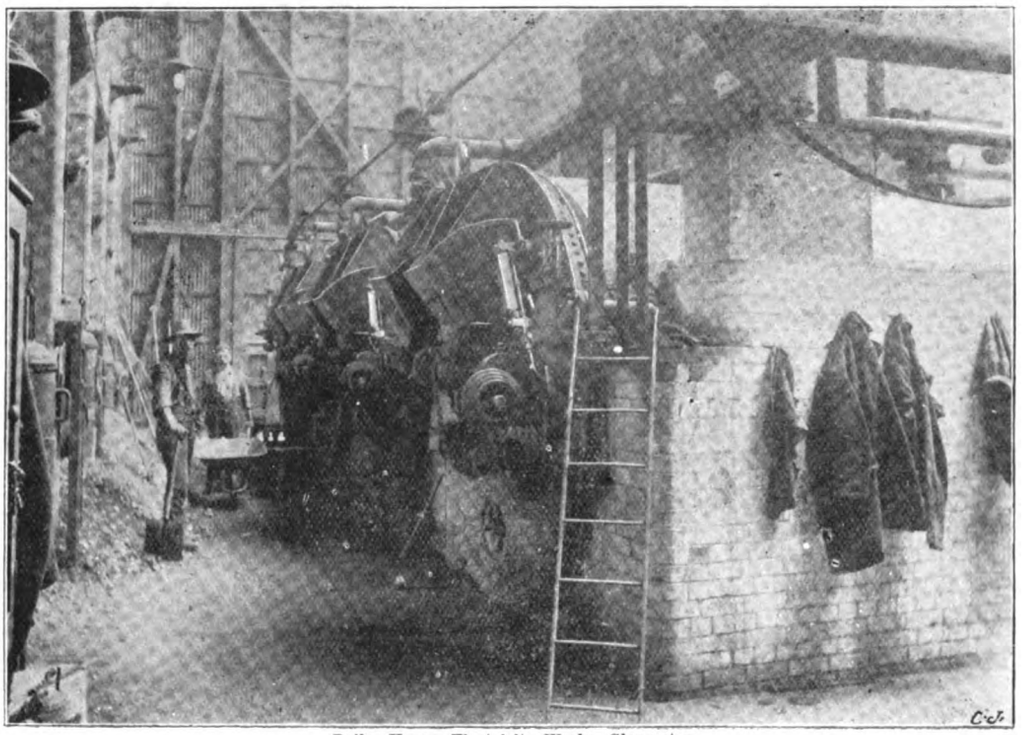


Plan of Electricity Works and Refuse Destructor, Gloucester.

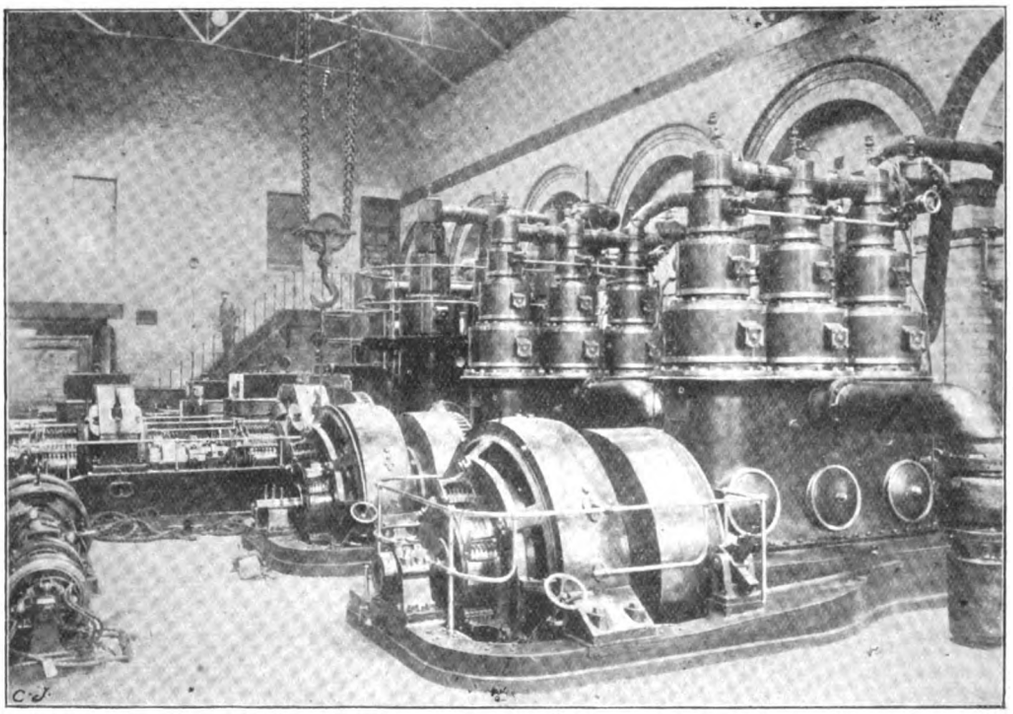
Digitized by Google

As regards annual upkeep, taking the cost of a brick chimney at £1,500, and allowing 6½ per cent. for interest on capital expenditure, depreciation, etc., an annual expenditure will be incurred of £97. 10s. For a forced-draught system the above charges may be taken at 8 per cent., which on a capital expenditure of £350 means an annual payment of £28. The cost of running the motor which would be required to drive the fan, and using 54,000 units per annum at ¼d., is £56. Thus the forced-draught system is £13. 10s. cheaper, annually, than the chimney stack. This does not take into account the other advantages, such as greater control over fires, and therefore economy in coal consumption. If the air be heated on its way to the fires no additional expense is incurred, except a slight increase in the capital cost, while the conditions under which combustion takes place are so much improved that a reduction in the coal bill amounting to 7½ or even 10 per cent. may be effected.

The boiler-house is 61ft. in length, 48ft. wide, and 41ft. in height, and contains at present three boilers, each 30ft. long by 8ft. in diameter, and one 30ft. long by 8ft. 6in. The smaller boilers have a grate area of 38 square feet and a heating surface of 1,015 square feet, while the larger one has 37 square feet of grate area and a heating surface of 1,160 square feet. The respective evaporations are 6,500lb. and 8,000lb. of water per hour. The Lancashire boiler is eminently suitable for Gloucester, which possesses a clear, bright atmosphere and experiences few fogs. There are, therefore, no sudden demands for steam, such as occur in many manufacturing towns. Where these rapid demands are prevalent the water-tube boiler undoubtedly possesses advantages, but for ordinary steady conditions of working it cannot compare with the Lancashire type, which has the very considerable advantages of low first cost, economical steaming, and low repairs costs, not to mention the freedom from anxiety it ensures for the engineers who have to work



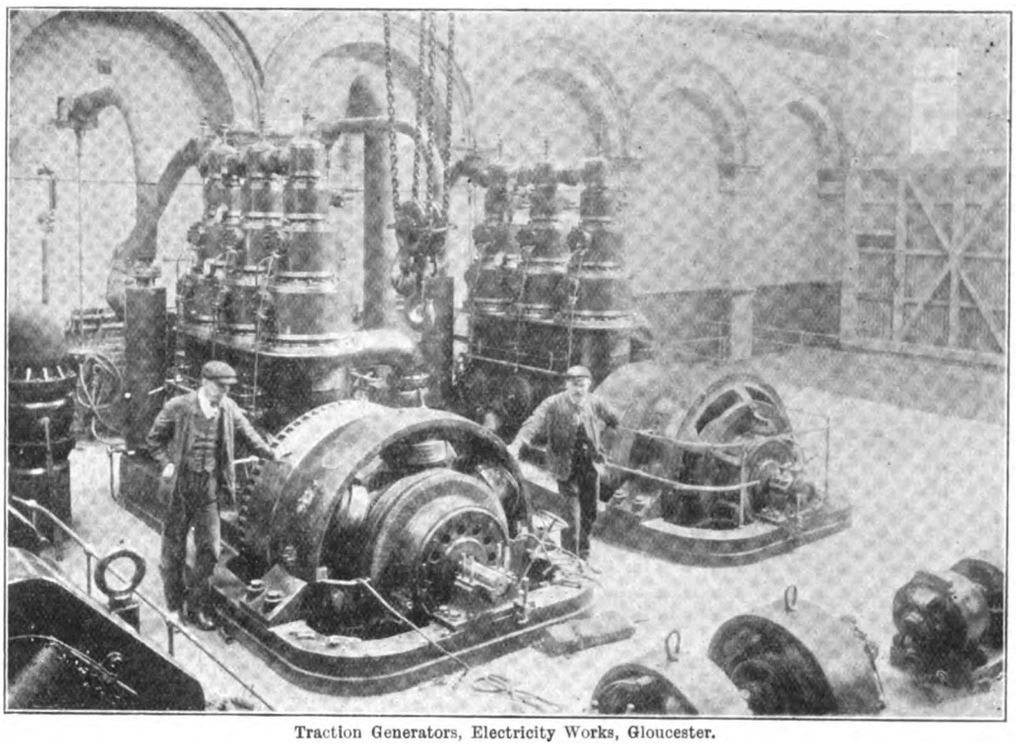
Boiler House, Electricity Works, Gloucester.



Engine Room, Electricity Works, Gloucester.

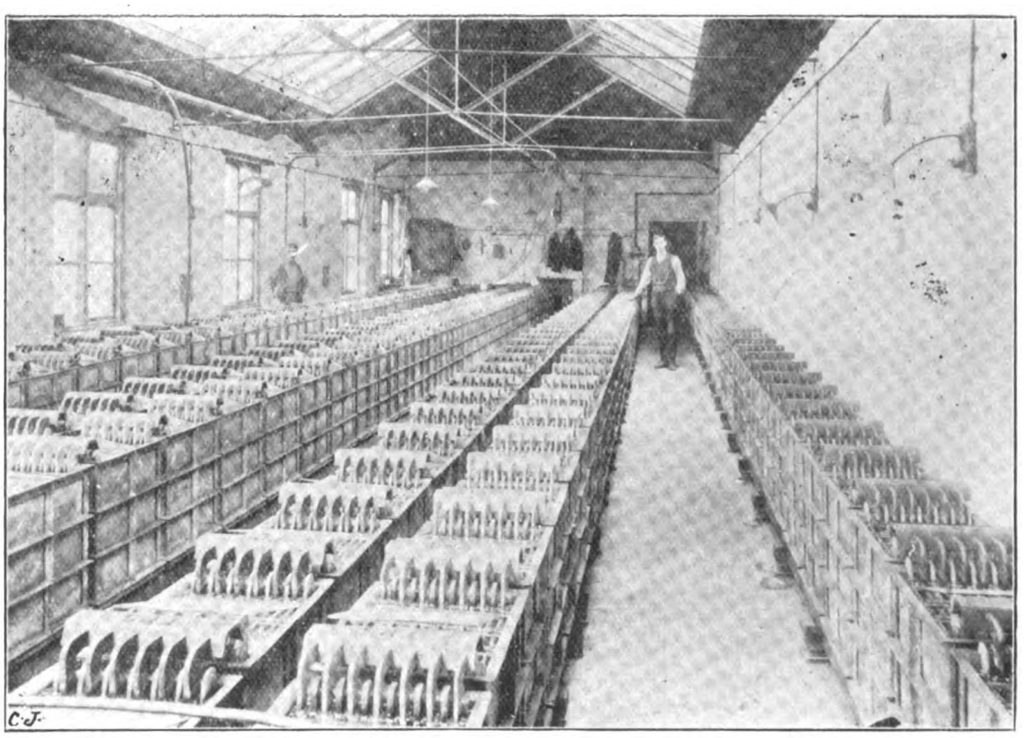
Digitized by Google

the boilers, which cannot be said of the water-tube boiler, with its rapid evaporation and small water space. All four boilers work at a steam pressure of 160lb. per square inch, and contain the usual fittings of Hopkinson's make. The main flue is provided with a Green's economiser, having 192 tubes in two sections and a by-pass flue. The scraping gear of the economiser is driven by a 5-kw. Bruce Peebles enclosed motor. Previous to passing through the economiser the feed water is heated in a Berryman feed-water heater. The latter is operated by the exhaust steam from the auxiliary plant.



Traction Generators, Electricity Works, Gloucester.

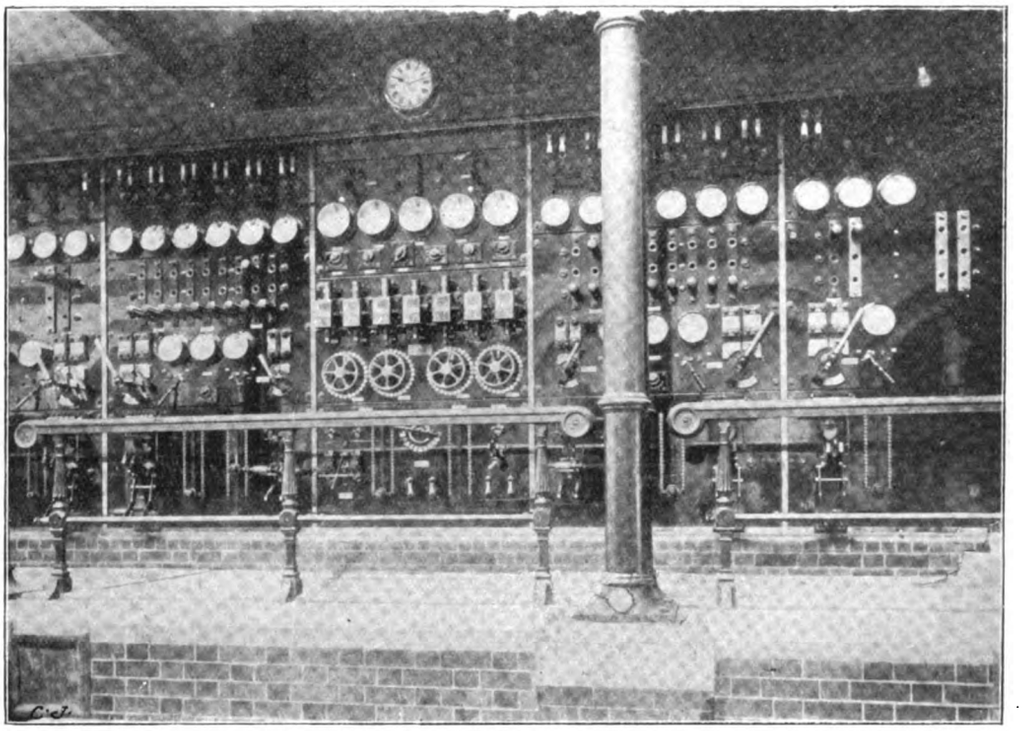
The pump-house is situated at the west end of the boiler-house, and contains two pumps, one an Evans compound double-acting flywheel pump, the other being of Messrs. Weir's manufacture, and of the type associated with their name. Both pumps draw their water direct from the feed tank, which is placed above the pump-house, and has a capacity of 3,500 gallons. The feed water consists of a mixture of canal water and condensed steam, and gravitates from a branch on the condenser discharge pipe to a sump near the boiler-house. From the sump it is lifted through a Mather and Platt feed-water filter to the feed tank. The water is raised from the feed sump and elevated to the tank by means of a 1½in. centrifugal pump driven by a 1½-h.p. motor, also of Mather and Platt's make. The motor is started and stopped automatically by a patent switch, operated by the water-level in the overhead tank. The action is very simple. A wooden float in the tank is connected by a chain to the switch lever, the chain passing through a slot in a flat lever, with an iron weight on each side of it attached to the chain. When the water in the tank is low the float falls, pulling the chain and the lower weight, which raises the switch lever and starts the motor. When the water rises to its normal level again, the top weight pushes the switch lever down and stops the motor. The main steam-pipe in the boiler-house is



Accumulator Room, Electricity Works, Gloucester.

Digitized by Google

8in. in diameter, increasing to 10in., the connections to each boiler being of 6in. diameter. Water-pockets are fitted at the junction of each engine branch with the main steam-pipe. There are no steam-traps on the main range, or, indeed, in the station, which is, perhaps, an unique feature.

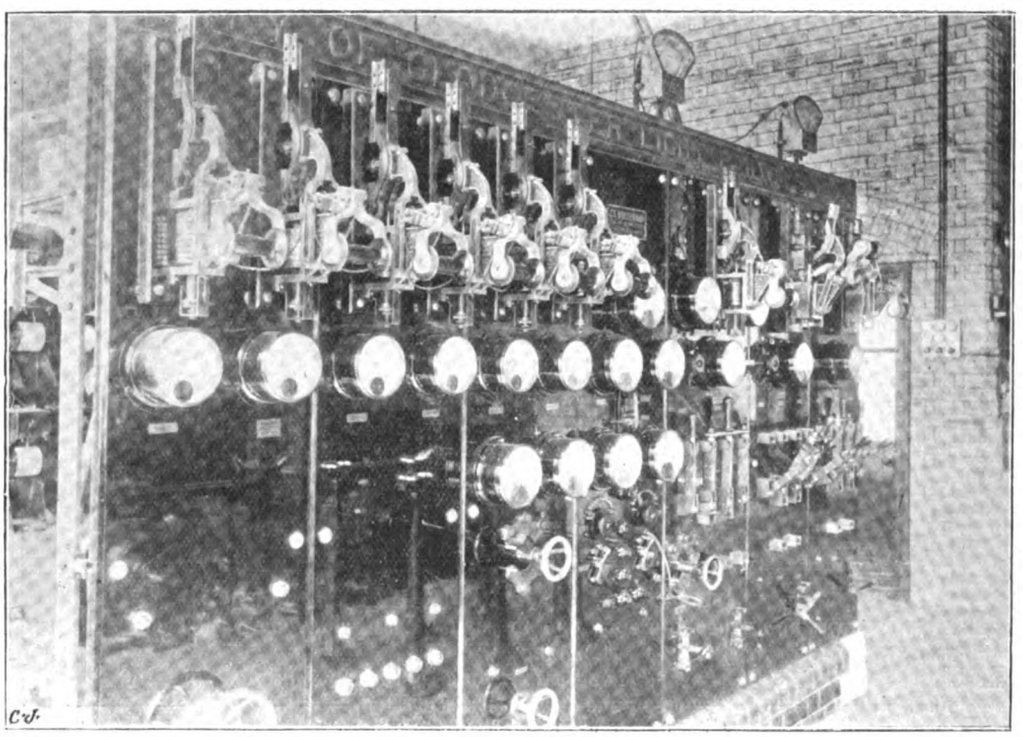


Main Lighting Switchboard, Electricity Works, Gloucester.

The feed system is duplicated, so that in the event of a breakdown to the hot feed pipe, or the economiser, the boilers could be fed through the cold feed pipe. A 3in. auxiliary steam range supplies steam to the condensing plant, pumps, etc. All the steam and exhaust pipes are lagged with removable magnesia covering, and the pipe joints are fitted with Lonsdale's removable steel flange boxes packed with felt.

The engine-house is 96ft. in length, 37ft. wide, and 38ft. high. The interior walls are built in buff bricks, with a dado of brown glazed bricks. The floor is laid with the Papyrolith Company's patent paving. The switch-room runs along the south side of the engine-room, and is open to it. The condenser pit is situated at the west end of the engine-room. The chief engineer's and chief assistant's offices overlook the engine-room, and access to them from it is provided by means of an iron staircase.

A 10-ton overhead travelling crane spans the engine-room. It was made by James Spencer and Co., and is operated by hand from platforms running the whole length of the crane girders. The engine-room contains at present three lighting and two traction sets, a balancer, a reversible booster, and a negative booster. The lighting sets consist of one 250-i.h.p. compound, two-crank Belliss engine direct coupled to two 75-kw. Silvertown dynamos of inverted horseshoe type; one 500-i.h.p. triple-expansion three-crank Belliss engine coupled to two 150-kw. Silvertown dynamos of the same type as the smaller set; and one 500-i.h.p. triple-expansion three-crank Willans engine direct coupled

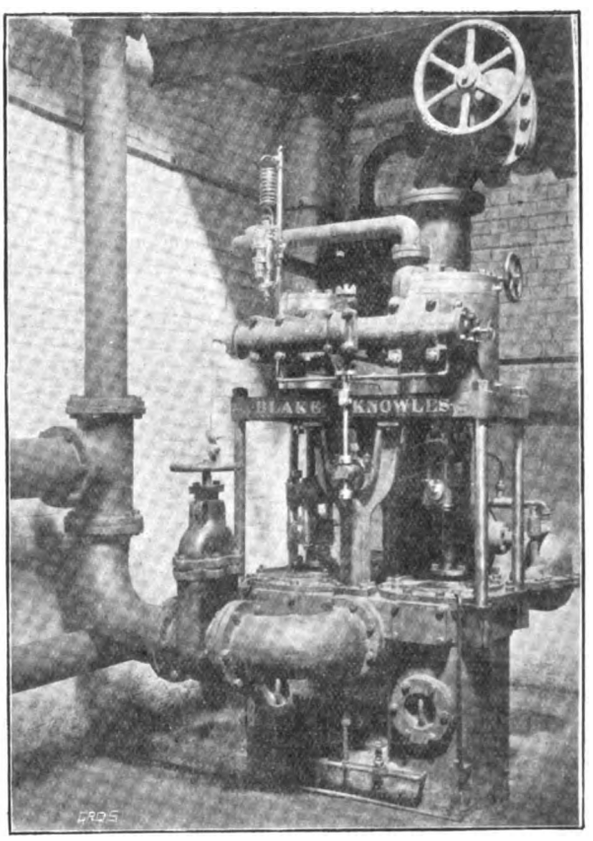


Traction Switchboard, Electricity Works, Gloucester.

Digitized by Google

to two 150-kw. Mather and Platt four-pole dynamos. The dynamos are all shunt wound to give from 220 volts at no load to 250 volts each at full load. The first two generators have smooth drum bar armatures, small commutators, and copper gauze brushes. When the traction plant was designed the possibility of adapting the existing lighting sets was considered, but the design of the sets rendered them totally unsuitable for this work. It may be pointed out that although the smaller engine was designed to work with a steam pressure of 130lb., it has never worked under these conditions, as it always takes its steam from the main range at a pressure of 160lb. This adaptability speaks well for the soundness of manufacture. The two traction sets, which are of equal size, each consist of a three-crank triple-expansion Willans engine of 300 i.h.p. direct coupled to a 200 kw. multipolar generator of the General Electric Company's make. The latter are compound wound to give from 500 volts on open circuit to 600 volts at full load. They are also arranged so that the series winding may be cut out of circuit, and the machines are then capable of running on the lighting load if required. A reversible booster, used in conjunction with the battery, is placed in the engine-room. It is of Crompton make, with Crompton-Macintosh winding, and is coupled in series with the battery, the object of the combination being to take the peaks of the load, and thus by equalising the work on the generator, it has been possible to instal a machine of smaller output than would be required if the generator had to deal with the whole of the fluctuations in the load. The regulation is performed automatically. The motor side of the combination takes its current from the lighting 'bus bars at a pressure of from 440 to 480 volts, and the generator side is capable of giving an output of 120 volts charging and 60 volts discharging, with a maximum current of 300 amperes for 10 hours. The negative booster is placed near the reversible booster, and consists of two open protected type four-pole machines, direct-coupled, and mounted on the same bed-plate. The motor side takes its current from the traction 'bus bars at a pressure of from 500 to 550 volts, and the dynamo side can give, at constant speed, an output of 400 amperes at eight volts continually. The battery consists of 260 cells of the E.P.S. Company's "P" or traction type. It is connected in series with the reversible booster, and in parallel with the generators.

The switch-room, as mentioned above, is open to the engine-room, but its floor is raised 4ft., and thus an uninterrupted view of the machinery, etc., is provided for the engineer-in-charge and the switchboard attendant. This is a distinct improvement on a gallery, owing to the absence of a long flight of steps, as, in case of emergency, the engineer can be in the engine-room with the least possible delay. The switch-room contains the lighting and traction switchboards. The former was made by Crompton and Co., and is of handsome appearance. It is divided into three main panels, the neutral and instrument panel in the centre with the positive and negative panels on the right and left respectively. The board is constructed of slate slabs fixed in a wrought-iron framework, which rests on a plinth of glazed bricks. Each set of two dynamos is coupled in series by a lead from each machine taken to the neutral bar, and the two outer leads are run to their respective sides of the board. Thus each set is self-balancing. Modern practice in three-wire systems is to run single generators, and obtain the balance of current by means of small units which are either steam dynamos or motor-generators. This method may be preferable in large stations where there are several sets running, but in small stations where the out-of-balance current is comparatively light the advantage lies distinctly with self-balancing sets, both from an economical and working point of view. The annual cost of running separate balancers is probably more than the interest on the additional capital outlay necessary to provide self-balancing sets, and in case of breakdown the result is usually a total failure of supply. This is not the case with self-balancing sets, as, should one machine break down, the other can usually maintain its own supply until another set can be switched into circuit, and thus only half of the town is in darkness. All the dynamos are coupled up to the 'bus bars on both sides of the board through minimum-current automatic cut-outs, designed to break circuit when the current falls below 10 per cent. of the full load. Duplex fuses are also inserted with two-way single-pole switches. In circuit with each dynamo is a Crompton shunted ammeter, and a dead-beat voltmeter is common to all the machines on each side of the system. The shunt-regulating switches and shunt-breaking switches are placed on the panels below the instruments. The feeders are taken off the top of the board. Each has an ammeter and a two-way switch with quick-break action and a duplex fuse. Below the feeder instruments are the vertical dynamo and feeder bars, which are connected to the main 'bus bars, at the back of the board, by screwed gunmetal plugs. In the central panel are the Kelvin voltmeters for pilot wires and main station 'bus bars. The neutral bar is earthed by a lead taken to the intake tank. In circuit with this connection is an automatic cut-out. It is arranged to short-circuit the ammeter when the earth current exceeds 10 amperes, leaving a direct connection from the middle wire to earth.



Blake-Knowles Condensing Plant, Electricity Works, Gloucester.

The traction switchboard, which is also constructed of slate, contains seven panels, the Board of Trade panel being placed in the centre with the three feeder panels on the left and the battery and two generator panels on the right. Each generator panel contains a reverse-current circuit breaker, designed to break circuit on the reversal of the current to the extent of 10 per cent., and in this event only. An ammeter, a single-pole main switch, and a double-pole change-over switch, are also provided. The latter is designed to enable the machine to be coupled either to the traction 'bus bars as a compound machine, or to the lighting 'bus bars as a plain shunt machine. There is an equaliser switch on each machine for paralleling. The battery panel is arranged in a very similar manner, but maximum breakers are used instead of the reverse-current type. The Board of Trade panel contains the usual instruments which are necessary to carry out the various tests required by the Board. They consist of the main ammeter, drop voltmeter, pilot switch, leakage current ammeter, and the shunt for the recording earth return ammeter. The resistance cellar is below the switch-room and contains the shunt-regulating resistances, feeder meters, etc.

The exhaust steam from the engines passes through a

Digitized by Google

16in. main under the engine-room floor to the condensers, of which there are three, all of jet type, and each capable of dealing with 10,000lb. of steam per hour. The two original sets are of Blake-Knowles make, and consist of compound engines, driving the air and circulating pumps direct. The third set, which was erected in 1904, was made by Summers and Scott, of Gloucester, and consists of a compound flywheel engine, driving air and circulating pumps of Edwards's type at a speed of 105 revolutions per minute. All three condensers are fitted with an automatic brake vacuum, making it impossible for the injection water to back up into the exhaust main. An automatic atmospheric valve is connected to the exhaust main for relieving the back pressure on the engines in the event of a breakdown to the condensers, or for running non-condensing if required. The condensing water is obtained from the canal basin. The intake pipe is placed at a depth of 3ft. below the lowest summer level of the canal. The water gravitates through 18in. cast-iron pipes to a large screening tank, from whence it is drawn by the circulating pumps. This tank is 14ft. long by 8ft. wide and 15ft. in depth, and is placed outside the engine-room. It is constructed with brick walls 14in. thick, resting on a concrete foundation. The tank is divided by a wrought-iron screen, the intake and suction pipes being on opposite sides of the screen. The screens are in duplicate. The condensed steam and injection water is discharged through 18in. pipes, with a fall of 1 in 76 to the opposite corner of the basin. An overhead tank has been fixed near the screening tank, into which water is pumped by a 1½in. centrifugal pump driven by a 2-h.p. B.T.H. motor. The water so raised is supplied by the works to the Streets Committee for street-watering purposes at a charge of 1d. per van load.

There are 40 miles of cables laid, all on the solid system. The feeders and distributors are of triple-concentric type with the neutral wire outside. They are laid in cast-iron troughs, and are surrounded with insulating compound. The arc cable, of which there is 15½ miles, is composed of a lead-sheathed, armoured, single $^{7}/_{16}$ and $^{7}/_{18}$ conductor laid direct in the ground. All the original cables, connections, junctions, etc., were made by Messrs. Callenders. Since the cables were laid we have improved the network by dividing it into sections, each supplied by one of the existing feeders, and linking these sections together through suitable fuses. The Board of Trade are now asking for this to be done in all low-tension networks. In our case on more than one occasion it has prevented us having a serious breakdown of the system. Owing to the heavy and rapidly increasing load in the centre of the town, it has been found necessary to construct a sub-station at the Cross, into which all three feeders passing that point are run. By this alteration the load on this district is carried by cables equivalent to a 1·2 square inch feeder. The sub-station is built underground, and is 12ft. 6in. long, 9ft. wide, and 7ft. 6in. in height. It is built of brickwork, lined with glazed bricks, with a dampcourse of "Tenax" 1in. thick in the walls and floor. It is well ventilated by means of an upcast shaft and small motor fan, the fresh-air inlet being an ordinary manhole cover at the pavement level. A neat switchboard by J. G. Statter and Co. is fixed in the sub-station, fitted with the necessary instruments. The total cost of the sub-station was £340.

Gloucester is exceptionally well provided with arc lighting, there being a total of 175 lamps installed. Fifty-two of these were included in the original scheme, the remainder were erected in 1904 to provide efficient lighting along the whole of the light railway routes within the city. The lamps are arranged in circuits of nine on 440 volts and of four on 220 volts. Each lamp base is fitted with an automatic cut-out and resistance to maintain the current should any lamp fail. The lamp columns are 20ft. high from the ground level. The lamps are suspended by steel wires, and are lowered for trimming and repairs by means of a winch fitted in the base of the columns. An automatic safety catch prevents the lamps from falling, should the suspending wire break. The lamp circuits are operated by switches placed in the base of the column of each end lamp on a circuit, and automatic time switches are now being experimented with and will be adopted if proved successful. Each alternate lamp is switched out at midnight. There are one or two groups of incandescent lamps installed in side streets, but owing to the keen competition of the local gas company the revenue from each is extremely small, and at the present time it hardly pays us to push their extension. The method of charging consumers is the maximum demand system, and Wright's indicators are used. The charge for lighting is 6d. per unit for any number of units up to the equivalent of 100 hours' use per quarter of the maximum demand recorded by the indicator, and 2d. per unit for all consumption during the quarter beyond the above. The charge for motive power is 3d. and 1½d. per unit respectively.

The capacity of the station plant is 1,150 kw., of which 400 are for traction purposes, and allowing one spare set of 300 kw. the net available capacity for lighting stands at 450 kw., which is equivalent to 15,000 8-c.p. lamps. Some idea of the increase in the demand for energy may be obtained from the fact that in December, 1900, the total equivalent number of 8-c.p. lamps connected to the mains was only 12,000, whilst there are now about 40,000, or about 2⅔ times the available capacity of the plant. The number of consumers has, in like manner, increased from 100 to 460. The load factor is 16·6, with a maximum load of 720 kw. The cost of production for the year ending March 31, 1905, is given below. It will be found to compare favourably with other stations of similar size :

| | |
|---|---|
| Coal | ·35 |
| Oil, waste, water, and stores | ·02 |
| Wages | ·21 |
| Repairs and maintenance | ·15 |
| Works cost | ·73 |
| Rents, rates, and taxes | ·08 |
| Management, office, and legal expenses | ·19 |
| Total cost per unit sold | 1·00 |

Owing to the rapidly increasing demand for energy, it was decided at the close of the past year to lay down large extensions to the plant, and these are now under construction. They consist of three Lancashire boilers, each 30ft. long by 8ft. 6in. in diameter, fitted with downtake superheaters; a 600-kw. steam generator; an electrically-driven surface condensing plant to deal with 30,000lb. of steam per hour; an electrically-driven feed pump; and the necessary extensions to the pipework, including a new economiser section; also the necessary additions to the boiler-house to accommodate the new boilers; and extensions and alterations to the refuse-destructor buildings, giving a greatly increased storage capacity.

### Refuse Destructor.

The construction of the refuse destructor has been dealt with by Mr. Read, the city surveyor, in his paper, but it may be briefly stated here that the destructor consists of two twin cells of Heenan type, each with a grate area of 66 square feet, or 33 square feet per cell. The Babcock boilers are placed above the cells, the combustion chambers intervening. Each twin cell was designed to deal with 25 tons of refuse per day, but the quantity dealt with often exceeds 30 tons per day. The large hoppers as originally installed were not found satisfactory, and we have replaced them by small hoppers holding about 5cwt., with an iron door between the bottom of the hopper and the cell. This door is counterweighted, and is operated by a lever worked by the charger on the tipping platform. When burning the normal quantity of refuse, charging is performed about every quarter of an hour. A fireman stationed on the clinkering floor drags the refuse on to the grates, and distributes it by means of a long rake. Two men are employed per shift of eight hours, but when the amount burned exceeds 25cwt. or 26cwt. an extra hand is required to assist the fireman. The wages of these men are 5½d. and 6d. per hour respectively. The Howden system of forced draught as fitted is a very successful feature of the plant. The temperature of the air in the hot-air chamber is about 220deg. to 230deg. F., with a draught equal to 2in. on the water-gauge. The motors and fans supplying the air work exceedingly well in spite of the trying conditions under which they are operated, and have cost very little for repairs. From tests which

Digitized by Google

have been carried out on the plant the temperature in the combustion chamber has been proved to exceed 2,000deg. F., and an evaporation of 1·5lb. to 2lb. of water per pound of refuse burnt was obtained with feed water at a temperature of 212deg. F. The steam pressure is maintained constantly at 160lb. The clinker is of very fair quality, and amounts to about 25 per cent. of the weight of refuse consumed.

MR. R. READ, A.M.I.C.E., CITY SURVEYOR, GLOUCESTER.

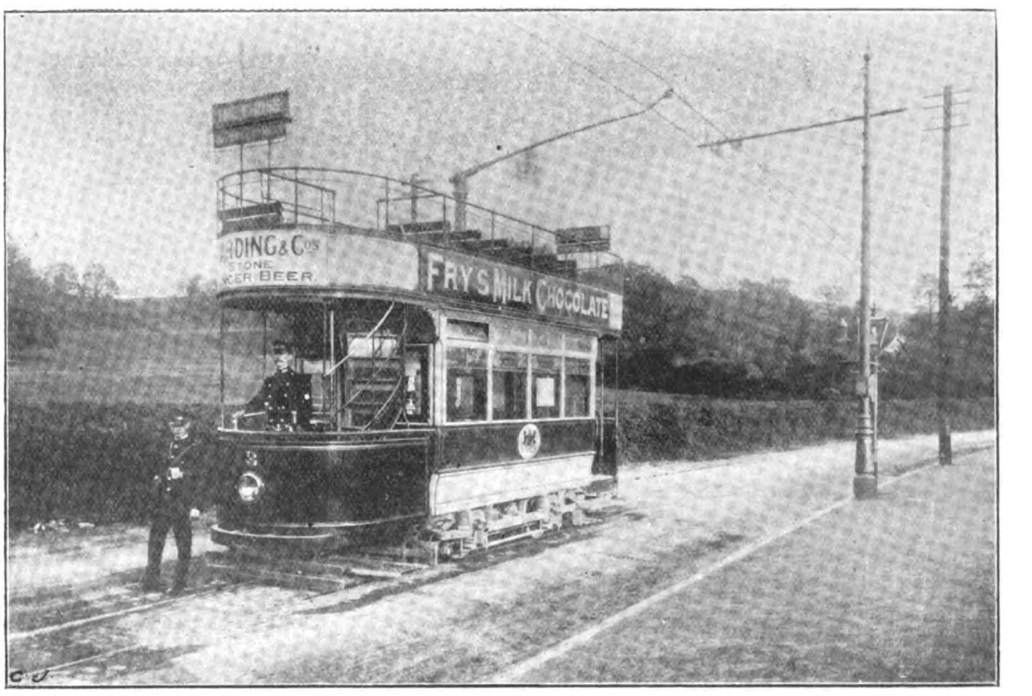
Troubles, such as are bound to exist in a brickwork furnace working at such high temperatures, have been encountered from time to time. The repairs usually consist of renewals of the firebrick work. It may be interesting to note here one of the most serious defects which has occurred—viz, the fusing and consequent failure of the steel joists carrying the brickwork above the entrance to the cells at the bottom of the refuse shoots. These were removed and brick arches substituted. The author is of the opinion that metal should not be built into brickwork exposed to great heat, as the brickwork tends to radiate the heat into the metal, which in the case of steel greatly weakens its strength, even if fusion does not occur.

## GLOUCESTER ELECTRIC TRAMWAYS.

The following details of the electric tramways system at Gloucester appeared in a paper read before the Incorporated Association of Municipal and County Engineers on June 3, by Mr. R. Read, A.M.I.C.E., the city surveyor.

The horse tramway was laid down in the city in 1879 on the Kincaid system, and this was worked by a company until 1902, when it was purchased by the Corporation for £26,000, and in its place the Corporation have laid down a system of electric light railways, covering seven miles of route inside the city and two miles outside the city, the latter being under the order granted to the Gloucestershire County Council, but laid down under the same contract by the Corporation, who work the line. The electric light railway is equivalent to 12½ miles of single track inside the city and 2½ outside, or a total of 15 miles of single track. Messrs. Alfred Dickinson and Co., of Birmingham, in conjunction with Mr. Robert Hammond, of London, were the consulting engineers for the tramways,

MR. E. W. A. CARTER, ASSISTANT CITY SURVEYOR, GLOUCESTER.

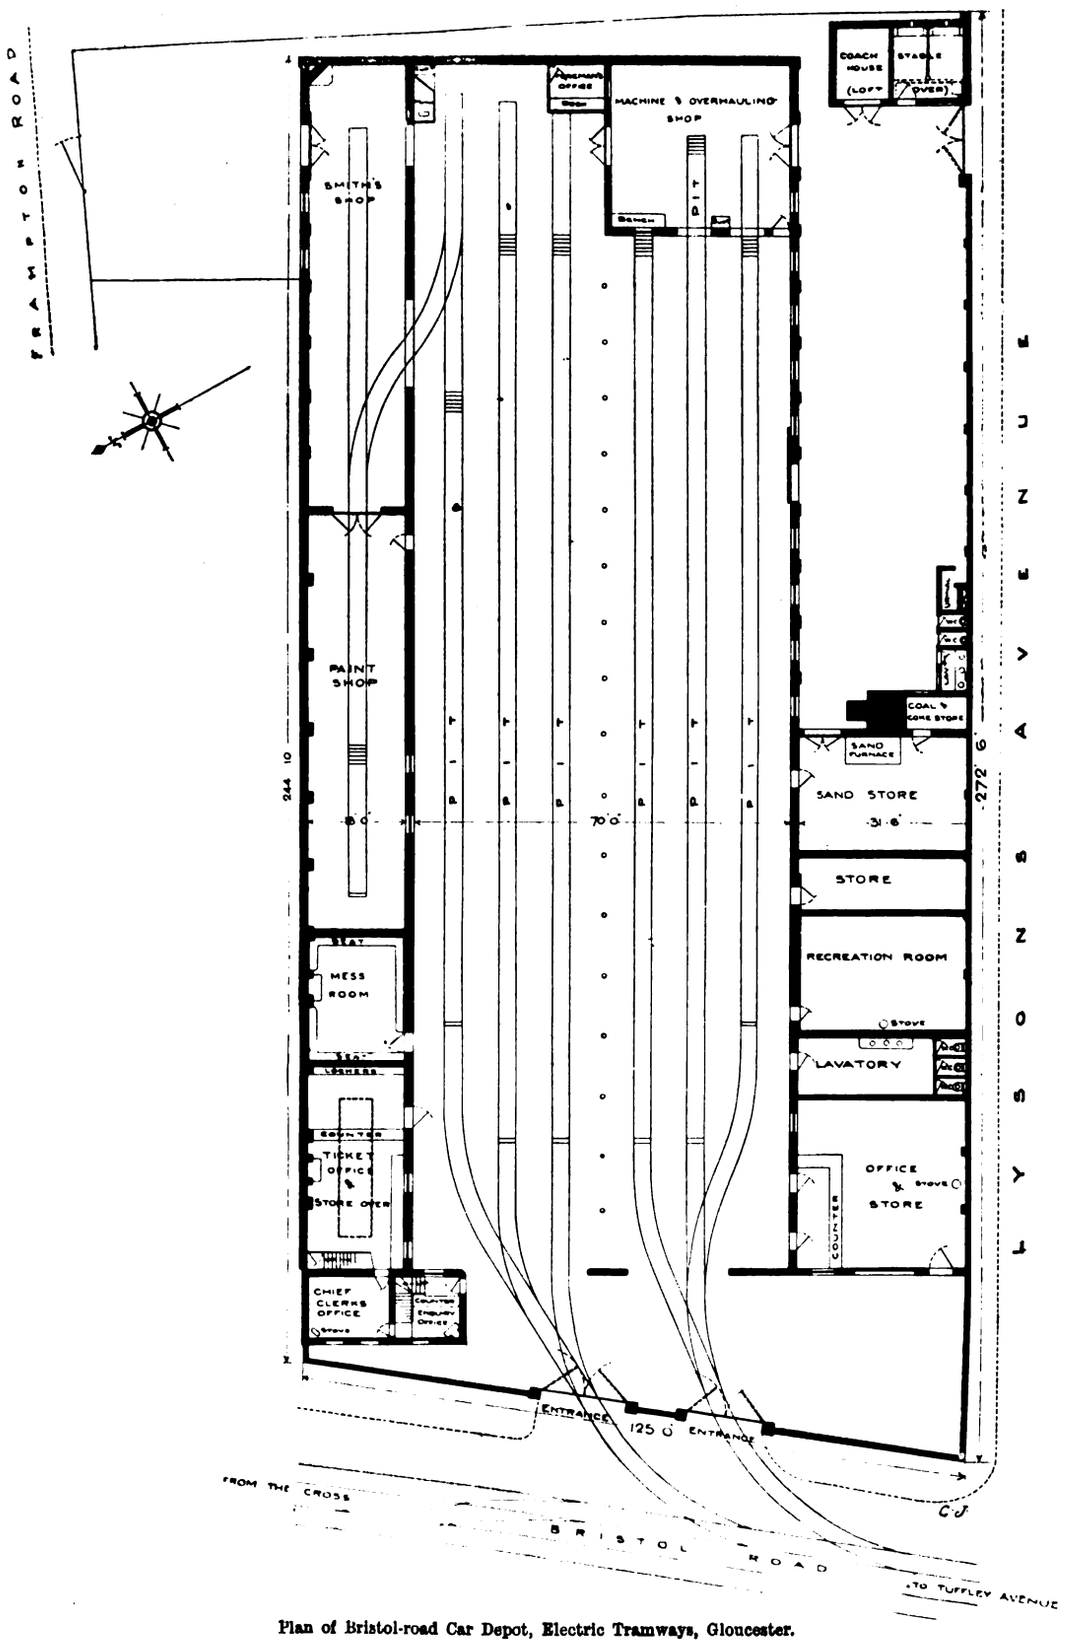


Gloucester Corporation Tramcar.

Mr. Hammond looking after the generating plant, while Messrs. Dickinson and Co. looked after the track, feeders, and overhead equipment, in conjunction with the author. The rails are 90lb. to the yard, 50ft. in length, 6in. deep, head 3¾in. wide, tread 2⅛in. wide, groove 1in. wide, guard ⅝in. wide, flange 6in. wide, 3ft. 6in. gauge, double copper bonded with 6/0 S.W.G. and 4/0 S.W.G., paved with 5ins by 4in. setts laid upon 6in. of cement concrete. The rails

Digitized by Google

are fished with ordinary fishplates, 60lb. per pair, six bolt. to each joint, tie-bars 8ft. apart, but the joints are not anchored to the concrete in any way. The rails were supplied by the Barrow Steel Company and the points and crossings by Messrs. Askham Bros., of Sheffield, the contract for the poles was let to Messrs. J. G. White and Co., and the overhead equipment to the British



Plan of Bristol-road Car Depot, Electric Tramways, Gloucester.

Electrical Equipment Company. The line is worked by 30 cars constructed by the Brush Electrical Engineering Company. The cars hold 18 inside and 23 outside—total 41 passengers. The cars' electrical equipment is by Messrs. Dick, Kerr, and Co. The work was commenced by Mr. George Law on Nov. 9, 1903, the first section was opened on May 3, 1904, and the last section in July, 1904. The overhead equipment is fed at every half-mile from underground cables laid in cast-iron troughs filled up solid with bitumen, each feeder pillar being fitted with switches for isolating the length and with telephone communicating with the car depôt. The overhead trolley wire is of copper "0" B.W.G., insulated at every pole, which are 40 yards apart. The car-shed was originally an old sawmill, and was purchased as one of the assets of the old horse tramway company. There being plenty of land in connection therewith, the author nearly trebled the size of the buildings, and provided six lines of car sidings, with pits, repairing shop for the electric motors, car-repairing and paint shop, smiths' shop, stores, offices, and messroom for the men, the cost of the additions and alterations being £5,030. 14s. 7d. The total cost of the electric light railway work inside the city was £128,436. 13s. 7d.

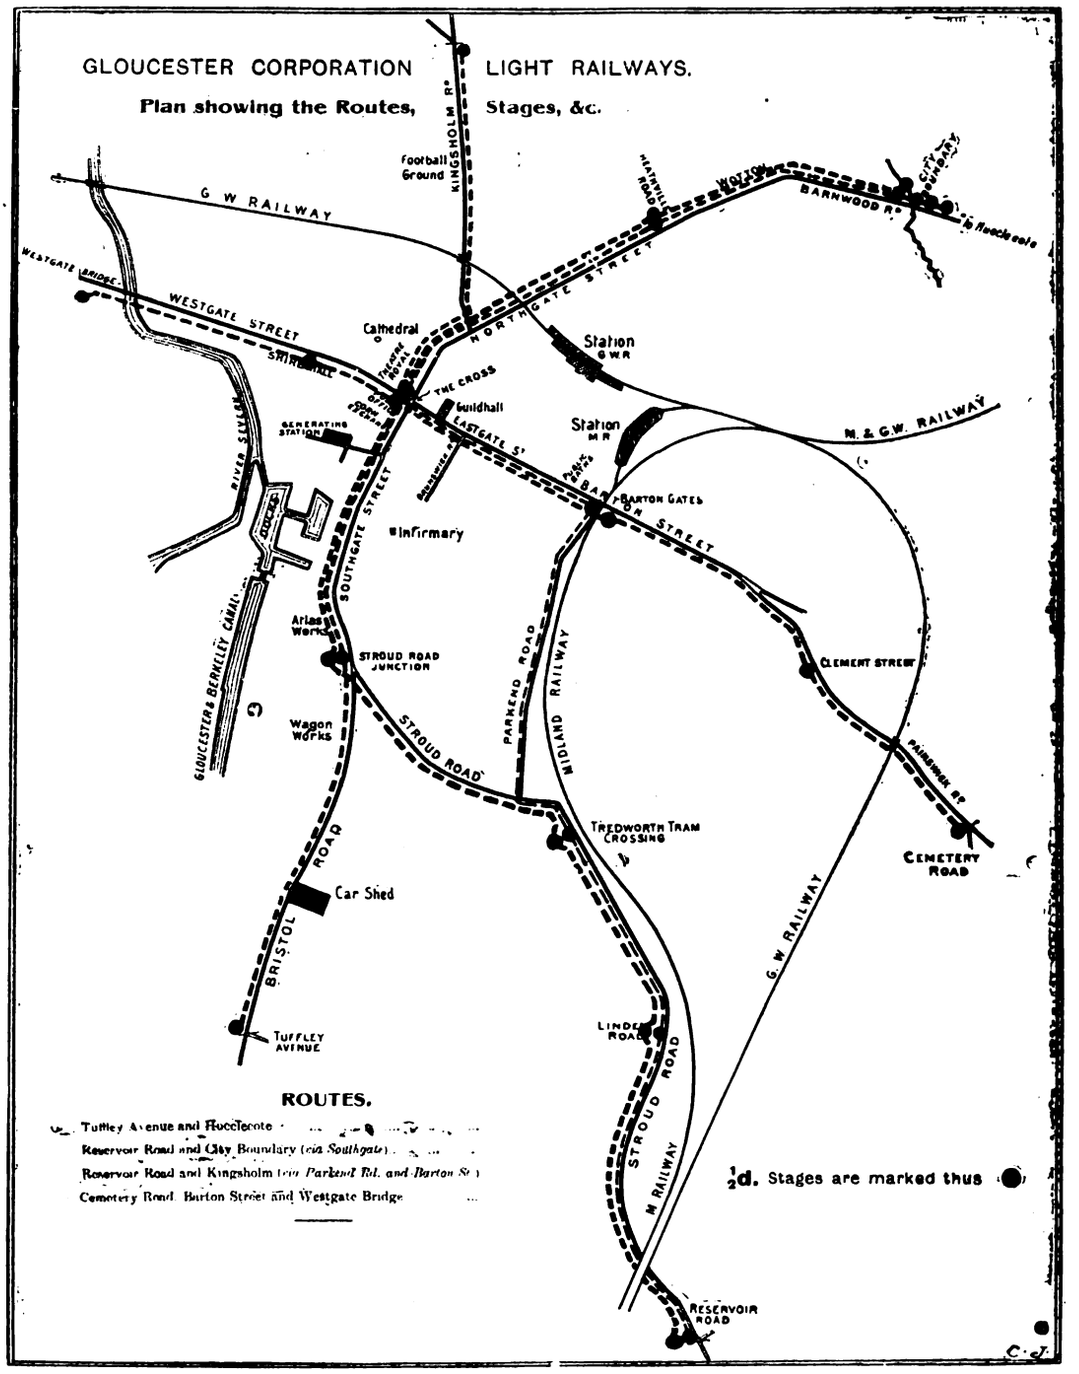
## THE PROTECTION OF ELECTRICAL INSTALLATIONS AGAINST EXCESS PRESSURE RISES.

BY ZODIAC.

With the gradual increase of the use of high-tension transmission schemes the efficient protection of the plant, cables, machine winding, etc., against the effects of excess pressure becomes of vital importance. Cases in which the line is directly struck by lightning are happily of comparatively rare occurrence, as in such instances it is very difficult, indeed, for any device to ensure freedom from insulation breakdown. On the other hand, disturbances in the pressure due to atmospheric inductive effects are quite frequent; indeed, such disturbances often occur during the summer months at times when the sky is perfectly clear. Such comparatively small voltage disturbances *are unable to jump the spark gaps of the normal lightning arresters*, and hence some provision has to be made for dealing with such excess pressures in order to avoid disturbances of the normal working voltage. In the case of installations using cables exclusively for the purpose of distributing the energy, these atmospheric disturbances do not occur; but here, again, rises in the pressure frequently result when transformers or additional feeders are switched in or out, resonance playing an important part in the phenomena.

A marked example of the disturbing influence on the pressure when switching in or out a transformer was recently observed when testing a 50 kw. 5,000-volt transformer which was fused with fuses blowing at about half an ampere, an electrostatic voltmeter reading to some 8,000 volts being used, and the connections being as shown in Fig. 1. The secondary circuit of the transformer being connected to the network, the high-tension switch, F, was closed, when the fuses immediately blew, the arc being quite a normal one; at this instant, however, the electrostatic voltmeter flashed over, thus showing that the voltage must have risen considerably above 8,000 volts, as the distance between the vanes was over ½in. The strength of the primary current at the moment of opening the circuit is not dependent on the load of the transformer alone, but is also dependent on the value of the E.M.F. wave at the instant the switch is opened. The switch used in the experiment was a quick-acting air-break switch, with an oil switch which breaks the arc at the instant when the E.M.F. wave is passing through its zero value; the current at the instant that the circuit is broken would be more or less reduced to zero, hence we have here a very clear argument for using oil-break high-tension switches in preference to air-break switches.

It is owing to the same reason that an alternating



Digitized by Google

current can be more easily broken than a continuous current of the same value and voltage. In cases where 500-volt motors have broken down, it has frequently been observed that the voltage at the time of the accident jumped across an air-gap which should have been amply sufficient to withstand a much higher voltage. It will probably be found in such cases that the voltage has originally punctured a weak spot in the armature insulation, when, owing to the strong magnetic field, the resulting arc would be suddenly extinguished, thus giving rise to an oscillating current in the windings (having a very high periodicity); hence the machine field windings would tend to act as a transformer, thus producing a voltage which

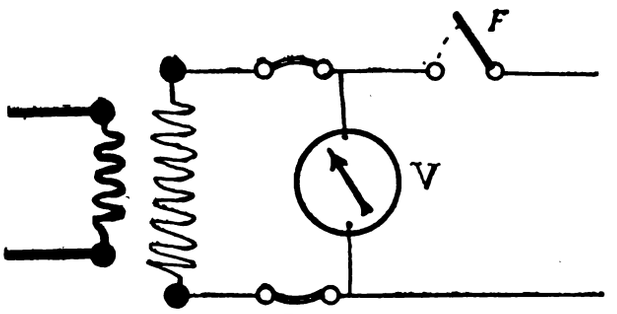


FIG. 1.

may be anything in the neighbourhood of 6,000 to 10,000 volts. Innumerable cases of breakdowns occurring to cables and machines, the cause of which could not have been either lightning discharges or defective material, are doubtless due to the above-mentioned phenomena. It would, therefore, seem essential that all installations, whether high-tension or low-tension, should be provided with suitable excess pressure arresters quite independent of the ordinary lightning arrester. The difficulty, however, in this case arises from the fact that the spark-gap in the case of low-voltage installations has to be made very small indeed; for instance, a 2,000-volt installation would have to have spark-gaps set at a distance of 1·4mm. in order to afford protection against pressure rises exceeding 4,000 volts, as shown on the curve given in Fig. 2. Such small gaps are readily bridged by dirt or insects; in fact, in

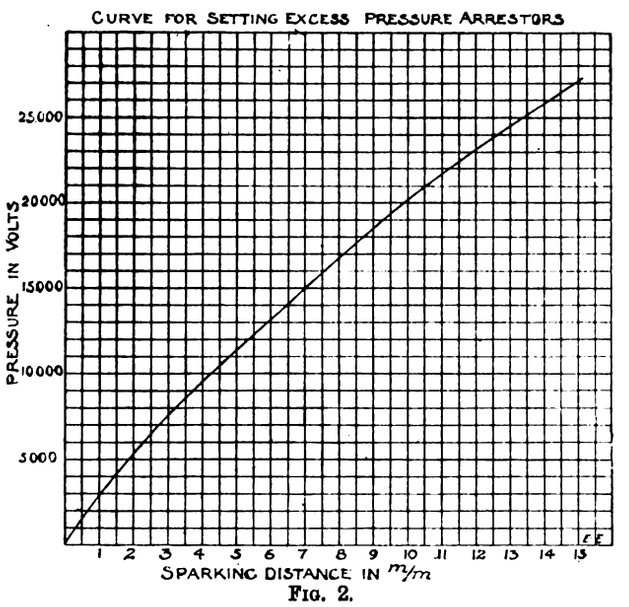

FIG. 2.

actual practice blow-flies frequently cause these excess-pressure arresters to operate, hence high resistances are placed in series with the excess-pressure arresters, so that the current to earth is of so small a value that it does not in any way affect the normal voltage of the circuit, a small energy loss being quite sufficient to relieve the excess pressure.

This is the main difference between the arrangement of the excess-pressure arrester as compared with the ordinary lightning arrester. In the case of a lightning arrester it is not permissible to place a large resistance in series with the arrester, since with the lightning discharge the amount of energy flowing through the arrester is very considerable. Fig. 3 shows diagrammatically a horn-type arrester in which an electromagnetic blow-out arrangement is provided for extinguishing the arc. Such an arrangement would not be permissible in the case of a lightning arrester, as, owing to the high frequency of the lightning discharge, the inductance offered by the electromagnet would seriously affect the operation of the arrester. In the author's opinion these electromagnetic blow-outs are quite unnecessary, and it is questionable whether the ordinary excess-pressure discharge is not of such a high frequency as to be affected, to some extent, by the impedance of these

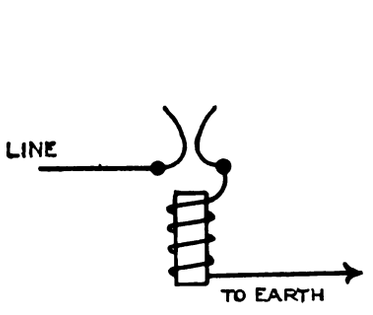

FIG. 3.

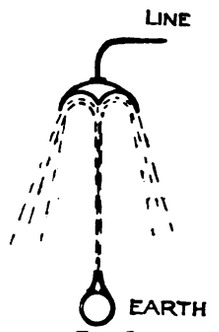

FIG. 5.

blow-out coils. Various forms of non-inductive resistances have been used by different firms. One of the most frequently used resistance consists of an earthenware pot about 10in. in diameter and some 2ft. high. From the top of this pot is suspended a metal plate connected to the line, the bottom of the pot consisting of a metal plate, which is effectually earthed. The whole is filled with water so that the upper plate is thoroughly immersed, thus forming a non-inductive resistance (see Fig. 4). In the case of a three-phase circuit three such resistances are used, one in circuit with each arrester.

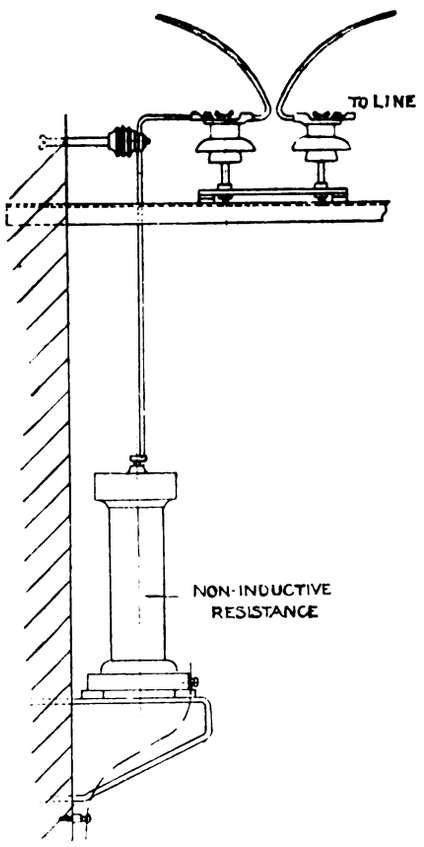

FIG. 4.

For hydraulic installations where a continuous supply of water is always available, the non-inductive resistance illustrated in Fig. 5 can be conveniently used. In this case it will be noted that a jet of water is used, which, by striking a special-shaped bell-mouthed casting, forms an effective high resistance to earth. The value of these water resistances should be such that with the normal

Digitized by Google

working voltage the current to earth does not exceed 500 watts. This amount of energy, although it is quite negligible as far as its effect on the working of any ordinary circuit is concerned, is ample to dissipate any excess pressure. The resistance, of course, can be easily varied by altering the length of the water column or of the water jet as the case may be. In practical use care must be taken that the water supply is kept constant, any evaporation in the case of a pot resistance being made good, otherwise if the water supply were to fail the connection between the arrester and earth would be broken, the results of which might obviously be serious.

## INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

The full programme of the tenth annual convention of this association is now issued. The headquarters will be Edinburgh, as Mr. F. A. Newington is president, but meetings are also to be held at Glasgow and Aberdeen. The following extracts from the programme will show the exceptional attractions of this year's convention:

TUESDAY, JUNE 27.

Meeting at Edinburgh, at 10 a.m., at the North British Station Hotel. The Lord Provost, Sir Robert Cranston, has kindly consented to be present and welcome the association. Presidential address by Mr. Frank A. Newington, chief electrical engineer, Edinburgh. The following papers will then be read and discussed: (1) "Load Factor: its Effect upon an Electricity Station," by Councillor Sinclair, chairman of the Electricity Committee, Swansea; (2) "Street Lighting," by Mr. E. E. Hoadley, chief electrical engineer, Maidstone. At 2.45 p.m, brakes starting from the hotel will convey the members and visitors to Dewar-place and McDonald-road generating stations. At 8.30 p.m. there will be a reception at the City Chambers by the Lord Provost, Magistrates, and Council.

WEDNESDAY, JUNE 28.

Meeting at Glasgow, at 10.30 a.m., at the hall of the Institute of Engineers and Shipbuilders in Scotland, 207, Bath-street, Glasgow. The Lord Provost of Glasgow, Sir John Ure Primrose, Bart., has kindly consented to be present to meet and welcome the association. The following papers will then be read and discussed: (1) "Notes on Costs and Tariffs for Electrical Supply," by Mr. Hamilton Kilgour, chief electrical engineer, Cheltenham; (2) "The Supply of Electricity in Industrial Areas, from a Municipal Point of View," by Councillor Hodgson, deputy-chairman, Electricity Committee, Salford. A private luncheon will be given by the Glasgow Corporation, to which members, associate members, and associates have been invited. At 3 p.m. the members and their friends attending the convention will be conveyed in vehicles provided for the purpose on a visit of inspection to the following works: Pinkston power station, belonging to the tramways department; Port Dundas electricity works, belonging to the electricity department; and St. Andrew's Cross electricity works, belonging to the electricity department. Arrangements have also been made for members and their friends to inspect the following sub-stations: Waterloo-street sub-station, belonging to the electricity department; Dalhousie-street sub-station, belonging to the tramways department; and the Yoker generating station of the Clyde Valley Electrical Power Company.

THURSDAY, JUNE 29.

Meeting at Edinburgh, at 10.15 a.m., at the North British Station Hotel. The following papers will be read and discussed: (1) "Extensions to Outlying Areas," by Mr. A. B. Mountain, chief electrical engineer, Huddersfield; (2) "Free Wiring and Supply on the Prepayment System," by Mr. A. R. Sillar, chief electrical engineer, Colchester. For the afternoon it is suggested that members should visit one of the following places: the Forth Bridge, the Falls of Clyde, Hawthornden and Roslin.

The association dinner will be held at the North British Station Hotel, Princes-street, Edinburgh, at 7.30 for 7.45 p.m. Evening dress. Tickets, 7s. 6d. each (exclusive of wine), may be obtained of the secretary before June 20, after which date the price will be 10s.

FRIDAY, JUNE 30.

The annual general business meeting of the association will be held at 10.30 a.m. at the North British Station Hotel, Edinburgh. Agenda: (1) Election of president for 1906; (2) place of meeting for convention, 1906; (3) election of officers and council for 1906; (4) annual report of the council; (5) balance-sheet for year ending Dec. 31, 1904. For the afternoon trips are aranged to Callander, Aberfoyle, and the loch for those who do not go to Aberdeen.

SATURDAY, JULY 1.

For the Aberdeen meeting visits have been arranged to the Aberdeen electricity works and car repair depôt, etc., during the morning under the guidance of Mr. J. A. Bell, the city electrical engineer. At 1.30 p.m. a private luncheon will be given at the town hall by the Aberdeen Corporation, to which only members, associate members, and associates will be invited. For the afternoon an excursion has been arranged to Ballater and Braemar, which will extend over Sunday. Other excursions from Edinburgh have also been organised for those who do not go to Aberdeen.

The secretary of the association, Mr. C. McArthur Butler, has arranged with the railway companies for those attending the convention to obtain return tickets from any station at a single fare and a quarter on production at the booking office of a certificate issued and signed by him. Applications for these certificates and for accommodation in any of the arranged excursions should be made to him promptly at Staple-inn-buildings, Holborn, W.C.

## THE ELECTRIMONGER.

BY B. C. H. J.

It's a wonderful thing, is the 'lectric!
I've studied it a month or two;
And to make my pile in a very little while
Is the project I have in view.
Though the hardware line is a good one,
It has this defective bar:
In Science it's a muff, but the 'lectric is the stuff
With its E = G over R.

It's a marv'lous thing, is the 'lectric!
But I've found how to make it go:
You get coloured wires and you tie 'em up with pliers
And nail 'em all around the show,
One end is hitched to the cut-out,
The other end goes to the lamps;
And if you are wise, you'll calculate the size
By a-multiplying volts by amps.

It's a terrible thing, is the 'lectric!
Oh! many a good man it's killed!
Which has made me swear to take every care
To keep my soul unspilled.
With rubber gloves to the elbows,
And an insulating mat below,
I fills the cells, what rings the bells,
With soda and $H^2O$.

It's a genteel line, is the 'lectric
(Which the hardware line it aint);
It is nice to wear a professional air,
To be free from the tradesman taint (haw).
And soon my cup of glory
Full to the brim shall be
When I sign all correspondence thus:

John Jones A.I.E.E.

## WESTMINSTER STREET-LIGHTING.

The zeal of the councillors of the city of Westminster when street-lighting is concerned is amazing, and it is accompanied by a thirst for figures which must try the patience of the officials. Facts are apparently useless to satisfy that thirst unless they happen to agree with the preconceived notions of the councillors. Thus the full report of the city engineer, Mr. J. W. Bradley, which we reprint in this issue, is not considered satisfactory, and further figures from the town clerk and city treasurer are now asked for. The matter really under discussion is a much smaller one than would be supposed. A certain contract for the supply of sixty-six arc lamps has expired, and tenders were asked for lighting the streets in which these lamps were. The electric supply company's offer was recommended by the Works Committee for acceptance for a period of five years. The gas company also tendered, but their offer included a capital charge which, if spread over the five years, made the cost per lamp slightly higher. Instead of settling the question on its merits, the Council asked for a report on the lighting of the whole of the streets of the city by the two rival illuminants, in spite of the fact that present contracts prevent any extensive scheme being put through. This report clearly shows that there is practically nothing to choose between gas and electricity as far as cost is concerned. Mr. Bradley's conclusions in this respect are for the systems of lighting as actually used, and he has more reliable figures as to what results have been obtained than any other engineer we know of. For some years he had regular photometric trials made, which enable him to distinguish between the promises given on behalf of a particular system and the performance under service conditions. We are, therefore, content with his conclusions as far as they cover existing conditions. They show how close the rival illuminants are when the ordinary arc lamp is compared with the high-pressure incandescent gas lamp. When, therefore, the flame arc lamps are used with their increased candle-power from a given consumption of electrical energy, the pre-eminence of electric street-lighting will be assured. In Westminster the competition between gas and electricity for street-lighting is on equal terms, as the local authority is not the supplier of either commodity. Hence the usual plea of the gas advocates, that electricity succeeds by favour rather than by merit, does not apply. This may account for the strenuous effort of the gas company to secure the present contract.

## METERS.

The accuracy of measurement is absolutely necessary in all commercial transactions. The suppliers of electrical energy assure their customers that nothing in commerce can be measured with greater accuracy than the commodity they supply. The consumer has to take what is told him on faith, for few are conversant enough with applied science to determine for themselves the exact value of this assertion. Men of science with reputations at stake, as well as the sellers of the commodity, vouch for the truth and exactitude of the measurements, and the commonalty believe what it is told, purchases, and pays accordingly. The tale is quite true. The assertion cannot well be denied, yet measuring instruments, like the schemes of mice and men, "oft gang agley." So far as theoretical assumption is concerned, electrical measuring instruments approach perfection among measuring instruments, but, after all, they are more or less mechanical constructions, and, like all such constructions, are liable to troubles and failures. Absolute perfection in mechanical constructions borders on the impossible. They

Digitized by Google

are subject to a variety of deteriorating influences, hence the necessity of constant supervision. Then there is another source of error which may be likened to the personal error involved in all investigations. Errors from this source are due to misreadings, mis-entries into books, and such like things. The broad question which the public needs to consider is whether the percentage of error from all sources is large enough to cause distrust. We are of opinion that, on the whole, electrical measurements are more accurate than any other class of measurements whatsoever. A committee of the London County Council reports upon the results of testing carried out by their officials in some disputed cases. Out of eight cases mentioned, seven errors are directly traceable to human failings. Thus in two cases where meters marked two hundred volts were used on one hundred-volt circuits, the division by two was forgotten, and the consumer overcharged. Other cases were due to the meters being incorrectly marked by the makers. The cases given are typical, and serve to show, as we have said before, the necessity of supervision of the meter-reading staff. Every effort may be made to avoid clerical errors or mistakes in reading, but such will occur. On the whole, we think the report confirms all that scientific men and suppliers say about the efficiency of electricity meters.

## CORRESPONDENCE.

### TERMS AS BETWEEN ELECTRICAL MANUFACTURERS AND ELECTRICAL CONTRACTORS.

SIR,—As it is evident from information received that a misunderstanding exists as to the terms upon which electrical manufacturers should supply their goods to members of the Contractors' Association, my committee are desirous that it should be generally known that the preferential discount of 2½ per cent., as provided under the original agreement between the Electrical Manufacturers' and the Electrical Contractors' Associations, ceased with the termination of the agreement, and should in no way be taken into account as from Jan. 1 last.—Yours, etc.,

W. DAVENPORT, Secretary.

## OBITUARY.

### John Munro.

We regret to record the death of a gentleman—little known, perhaps, except as a name to this generation of electrical men—who was greatly revered by those who knew him well. The work "Munro and Jamieson," appreciated by hundreds of users, conveys little to those users of one at least of the *collaborateurs*. Of late years Munro led the life of a recluse, mixing little with his fellows, his extremely sensitive and retiring nature having received rebuff, which caused such retirement. Educated at Glasgow University under Lord Kelvin (then Sir W. Thomson), Munro devoted his attention to cable work, and was at least in one cable-laying expedition, during which period he became friendly with E. Almack, another man of talent and energy who left the profession for other fields of work. Coming back from cable-laying, Munro turned his attention to literature, and, though painstaking and correct in his work, had not that scintillating knack of writing which leads to pronounced success. He wrote many books, and frequently contributed to magazines and technical papers. Living all alone in a small house at Croydon, communicating little or nothing to his friends, few knew of his circumstances, but his old-time friends will ever remember him as they knew him in early days—a man of merit, with legitimate ambitions, a lovable disposition; a man, in fact, who was altogether too much of a gentleman to retaliate when rebuffed, and hence failed to achieve that success he so well merited.

## A STUDY OF SHORT-DISTANCE TELEPHONY.

BY VALENTINE RYAN.

*(Continued from page 733.)*

A few more stations can be added to an intercommunication system when required by running a cable to a junction box, and making the connections uniform with the other stations; all the contact studs on these stations are allotted, so that it cannot be rung up; the home contact should be left "blind," and the switch returned to it after each conversation. A better plan is to break the bell circuit, then the switch can be left anywhere. This method is found convenient when a desk telephone is required for the use of a manager in a large office, there being a wall set at the other end of the room. In the first place, the manager can use the telephone for his own convenience; when someone wants to speak to him, they can ring up on the wall set, and be answered by a clerk, who will notify to the manager, thus saving the latter some annoyance, the same being done when the manager requires to ring up someone.

Writing with reference to overhearing on intercommunication systems, it is stated in text-books (one also meets it in patent specifications) that this is due to induction and condensation. This is not entirely correct. The diagram below (Fig. 6) shows the connection for three stations, A, B, and C, arranged on a 10-way intercommunication system. Suppose A and B to be engaged in conversation, and C to place the line selector on the "line wire" A and B happen to be using, then, as shown

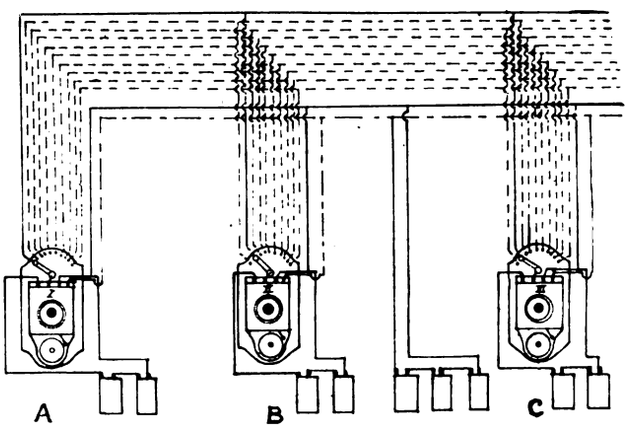

FIG. 6.—Connections of Overhearing Station on Intercommunication Systems.

in the diagram, when C is speaking A and B are in parallel with C in series. When B is speaking, A and C are in parallel with B in series; under these circumstances the third station is in the speaking circuit, so the overhearing is quite independent of induction and condensation—this point has been apparently overlooked. If a spare wire was left in the multiple cable and earthed at a few points, it would assist materially in reducing the overhearing; in similar cases, where direct working telephones are used and a common speaking battery employed, much the same happens. The station that is rung up will be found in parallel with the overhearing station; the third station remains in series with the battery.

From time to time so-called automatic intercommunication telephones have been placed upon the market. These are intended to save the trouble of moving the ordinary lever switch round a semicircle of contacts, and moving it back again to the home contact when the conversation is finished. In these instruments this disadvantage is avoided by the introduction of a multitude of evils; the lines are provided with individual switches which make contact with a common speaking bar, and this bar is tilted when the receiver or micro-telephone is replaced in the normal position. Each of the switches, the speaking bar, and the lever that tilts it, are all controlled by delicate spiral springs. The single spiral spring of the ordinary telephone is the weak point of its construction, yet in the instruments referred to more delicate springs are used in large numbers. The micro-telephone must be taken off the hook before one can ring, or the particular line selector one has moved will spring back again, when this is done. This is anything but an

Digitized by Google

advantage. Of course, the working of the apparatus should be the reverse, but this would necessitate the introduction of a rather elaborate gear.

The adjoining Figs. 7 and 8 show a telephone* of very graceful design, which is being marketed by Stanley and Patterson, of New York. To the development of the principles embodied in this instrument one expectantly looks for the final solution of this vexed problem—viz., switchless intercommunication telephones.† The simple act of pressing a particular push-button rings

FIG. 7.

up the desired station and also completes the speaking circuit. This is the first telephone which enables one to do this, and it must remain an axiom in the construction of all such telephones that have any claims to being called automatic. Fig. 7 shows the front view, and Fig. 8 is the back view, with the cover removed, of an intercommunication set. In this country a micro-telephone may be considered more up to date than the arrangement shown, but they are not used to the same extent in America as they are here. Each line is provided with a push-button and label. Towards the lower end of this instrument are shown

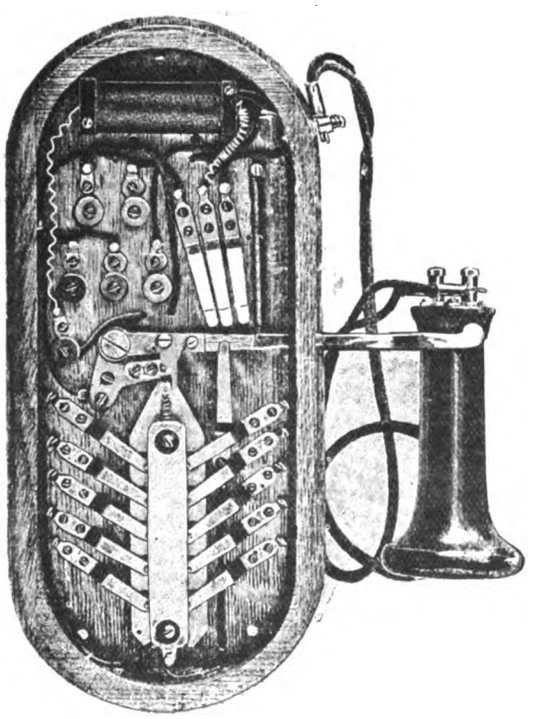

FIG. 8.

two plates, mounted one in front of the other; the outer one is the battery plate, the inner one is the common return plate, and moves in a vertical plane; normally it is held in the upper position by a spring. In it holes are drilled corresponding in number to and concentric with the push-buttons. On pressing one of these buttons, its tapered head is forced through a hole in the common return plate, the tapered edge impinges against the edge of this hole and forces the plate downward, until the head passes through; then the plate is pulled up by its spring and keeps the rivet-shaped head of the push-button from springing back. The tapered head of the push-button shank makes contact with the line spring opposite to it, and when the push-button is forced to its extreme limit it presses this spring against the battery plate, thus ringing up the station to which this particular push-button is allotted. The line springs mentioned are the two rows of diagonal springs shown, the ends of which form the terminals for the various lines. When the push-button is released it springs back, and is stopped half-way by the movable common return plate, and so connects the line

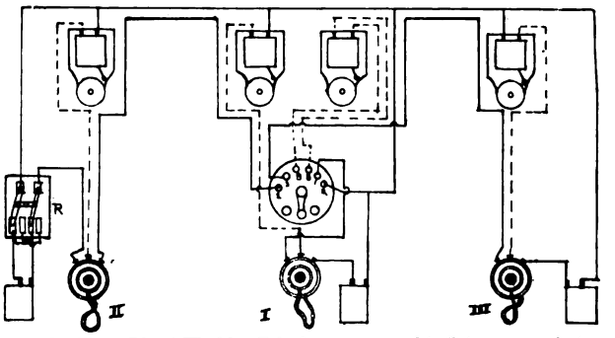

FIG. 9.—Three Direct-Working Telephones arranged to Intercommunicate.

springs to this plate. When the conversation is finished and the receiver replaced upon the hook, a pawl mounted on the hook engages a lug in the common return plate, and pushes the plate downwards far enough to release the push-button; the button is then free to spring outward into its initial position. Continuing its downward movement, the pawl or the receiver hook is thrown out of engagement with the lug on the common return plate, and this plate returns to its normal position.

Three telephone stations are often required to be connected up so that all can communicate. A favourite way of arranging for this is to place a six-point switch and extension bell at the intermediate station. Many persons are familiar with such installations working with induction-coil instruments. When direct working ones are used, the batteries at the outer stations are connected in series with that at the intermediate station; each then can communicate with the latter but not with each other—hence a reversing switch, R (Fig. 9), is placed at either of the outer stations. This is used to reverse the battery connections, connecting it in series with the ones at the other stations as may be required.

*(To be continued.)*

## LARGE DYNAMOS FOR JOHANNESBURG.

It will be remembered that Messrs. Siemens Bros. and Co. secured the contract for the supply of the generators for the new electric power station of the Johannesburg Corporation, which is being erected to the design of Messrs. Mordey and Dawbarn. The order included three direct-current machines, each of 1,350 kw. capacity; two smaller machines of 665 kw. capacity; two two-phase alternators of 1,350 kw. and one of 675 kw. The feature of the station is that power gas is to be used to supply the necessary energy, and this will be utilised in gas-engines which are being supplied by Messrs. Duncan Stewart and Co., of Glasgow. The first of these large direct-current machines have recently been tried at the Stafford works of Messrs. Siemens Bros. The test was made on the Hopkinson method, and gave results which were most satisfactory. The full-load efficiency was well above the guarantee, and the temperature rise on any part of the conductors of the machine was low. The commutation was also good, the machines running sparklessly with a fixed lead in spite of the fact that the field of one had to be weakened to secure the conditions of test. The two illustrations given herewith show these machines as erected for the Hopkinson trials, and give a good idea of the construction of the same. They are to be used for the direct supply of lighting and tramway load, and are com-

* *American Electrician.*

† Specification of patent in U.S.A., No. 710,065, of 1902, describes another arrangement designed for the same purpose.

Digitized by Google

pound-wound. The type of the machine is the Siemens 124, 2 H, which signifies that the armature diameter is 124in. The machines have 14 poles, and are arranged to be directly coupled on to the flywheels of the 2,000-h.p. Stewart gas-engine. The dynamo will thus be placed between the two cylinders of the engine. The range of output of each of these machines was specified to be as follows: as shunt machines, 2,815-2,410 amperes, 480-460 volts, at 100 revolutions per minute; as compound machines, 0-2,250 amperes, 500-600 volts at 103-100 revolutions per minute.

In one of our illustrations the upper half of the field-magnet system is removed, which enables the armature winding to be seen. The armature coils in this type of machine are inserted in the open slots in the core. They are carefully insulated with material for securing a high insulation which shall not be affected by moisture. This insulation is tested under high voltage before it is passed. The photographs give a good idea of the large size of these two machines, which can be judged by the workmen standing round them. This is due to the fact that they run at the low speed of

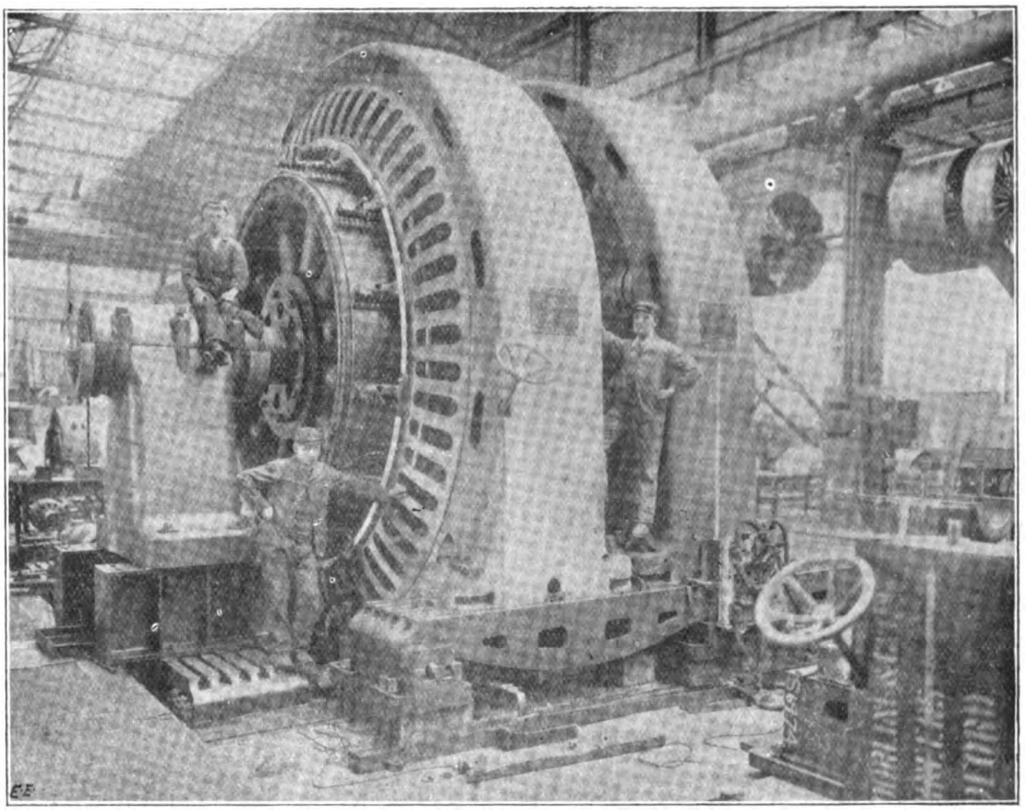

FIG. 1.—View of two Siemens 1,350-kw. Generators for Johannesburg, connected for Hopkinson test.

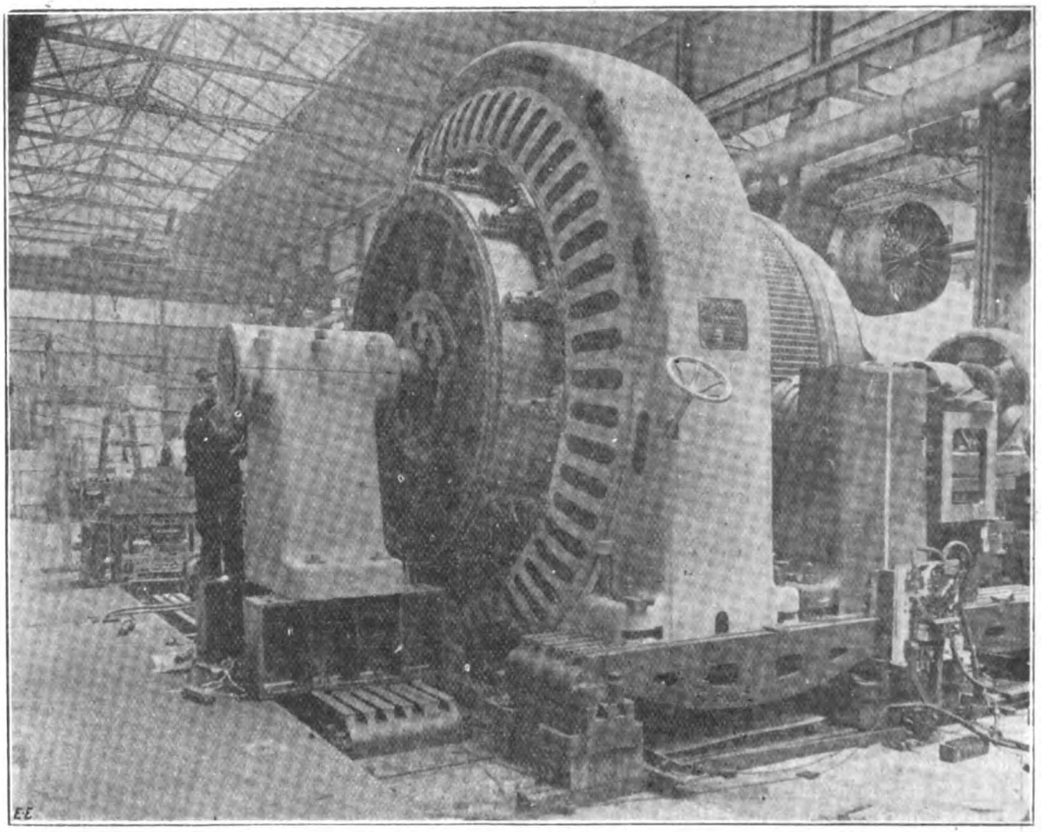

FIG. 2.—Johannesburg Dynamos with top half of one field magnet removed.

100 revolutions per minute. There will be some interesting information to be obtained from the Johannesburg station when these dynamos are at work, and we trust they will result in more orders for English manufacturers.

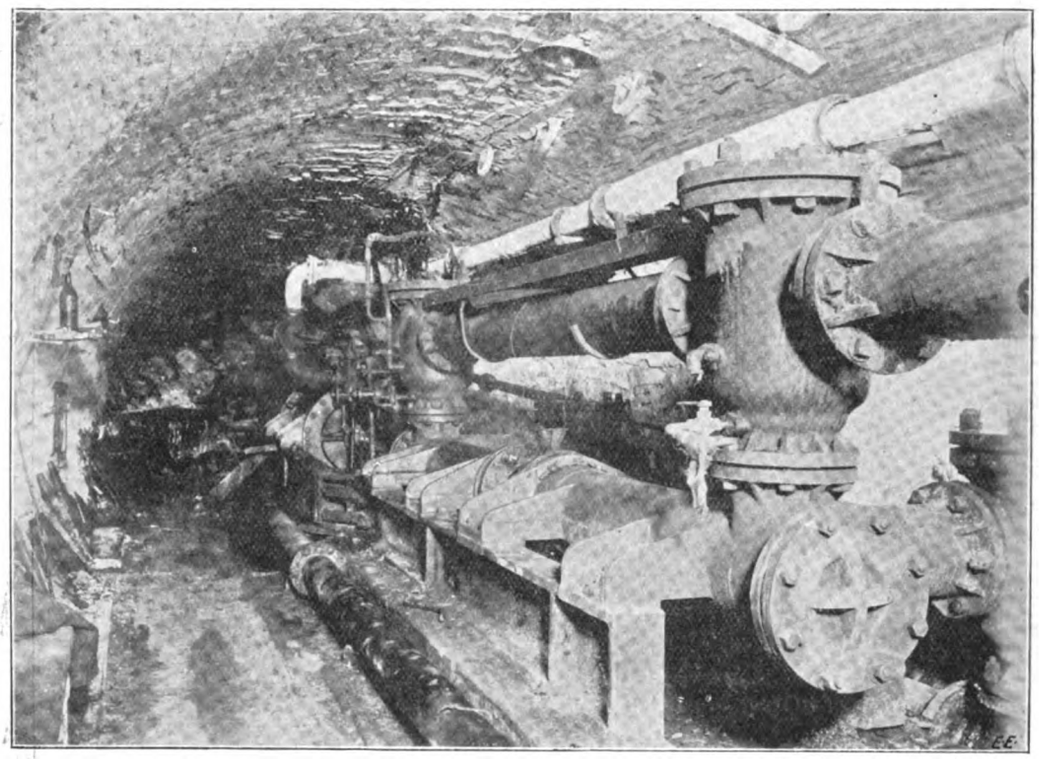

FIG. 1.—The High-Pressure Steam Pump at the Lewis Merthyr Colliery which has been displaced by Electric Pumps.

## ELECTRICALLY-DRIVEN HIGH-PRESSURE TURBINE PUMPS.

The Lewis-Merthyr Consolidated Collieries in South Wales were one of the first to adopt electrical working. Recently, when the question of high-lift pumping came to the fore, they decided to keep in line with the latest practice, and to instal an electrically-driven turbine and auxiliary centrifugal pump at their Coedcae pit, Hafod, near Pontypridd, these taking the place of an already existing steam-driven pump. The order for the work was given to the British Westinghouse Company, who, it may be mentioned, have carried it out to the entire satisfaction of the owners.

The following comparison of the old system with the new is of considerable interest. The steam-pump, which by the way is kept as a stand-by, is of a high-class type with differential valve gear and a condenser, and with steam and water cylinders 28in. and 9½in. diameter respectively, the latter having a 4ft. stroke. The full-speed duty is

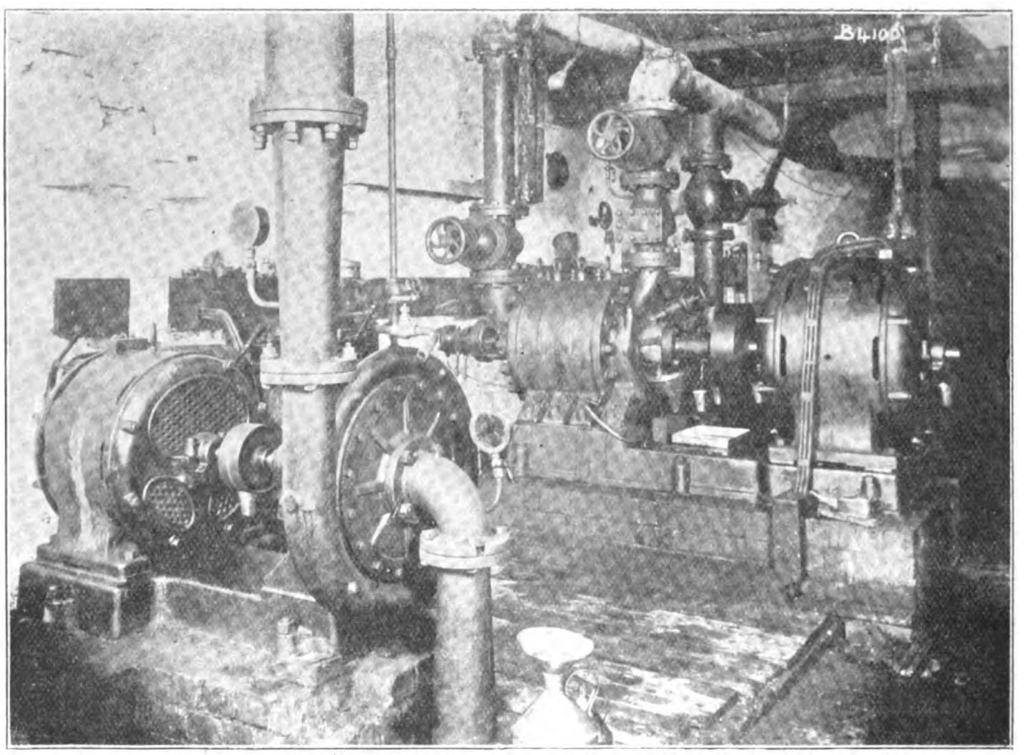

FIG. 2.—View of the New High-Lift Centrifugal Pump driven by Westinghouse Induction Motor.

25,000 gallons per hour against a head of 350ft. Steam is brought down the shaft from the boilers on the surface, this entailing the usual wasteful condensation in the pipes,

Digitized by Google

and occasioning the greatest inconvenience should a joint break. Fig. 1 gives a view of this steam-pump, and it may be mentioned that it occupies an area of 253 square feet (39ft. by 6ft. 6in.). Fig. 2 shows the new turbine pump, and also a small centrifugal pump, these being fixed in a heading close to the steam-pump. These are driven by three-phase current taken from the mains of the South Wales Electrical Power Distribution Power Company, the current being transformed from 11,000 to 450 volts at a sub-station on the colliery premises. A three-core armoured cable leads the low-pressure current down the shaft to a dividing box and switchboard fitted with an oil-break circuit breaker, fuses, and indicating instruments. From this board the current passes to the oil-immersed auto-starters of the motors. The larger pump is of the Worthington four-stage turbine pattern, while the smaller is a 4in. centrifugal pump of the same make, and both are direct driven by Westinghouse type "C.B." three-phase induction motors, the larger of these being of 60 h.p. The function of the smaller pump is to supply an overhead tank for feeding the suction of the larger pump, the supply being drawn from the various mine pumps.

It has already been mentioned that the old steam-pump occupies a ground area of 253 square feet, and it is important to note that this area is 10½ times that required by the turbine pump (8ft. by 3ft.), and 7½ times that required by both electric pumps, the area covered by the centrifugal pump being 5ft. 6in. by 4ft. 3in. The electrically-driven pumps possess a combined efficiency of nearly 70 per cent. when delivering 350 gallons per minute against a head of 342ft., this being a very good figure. The type of motor illustrated has a short-circuited rotor winding, and is eminently suitable for driving both turbine and centrifugal pumps in collieries, as well as elsewhere, there being no brushes or other rubbing contacts. The starting switches are wholly immersed in oil and are fitted with gastight covers, so that they are perfectly safe for mine use. The attention required is practically nil, as the bearings both of the motor and pump are self-oiling, and after they have been started the machines may be left entirely to themselves.

## TRADE NOTICES AND NOVELTIES.

### Sectionalising Trolley-Wire Insulator.

Mr. C. A. Schierwater, of Liverpool, has recently patented a trolley-wire insulator, which we illustrate herewith, which has for its object the sectionalising of the trolley wire should a fracture occur. It is also intended to ensure that the ends of the broken wire shall be disconnected from the circuit. The inventor's idea is that these insulators should be employed at every point of support, whether the trolley wire is suspended from poles or by span wires. From the illustration in Fig. 1 the general construction of the insulator can be readily followed. The trolley wires, 1, are attached to the metallic brackets, 2, which are connected together mechanically by the bolts, 6, and by the insulating bush, 8. The middle metallic support, 3, is attached to the span wire or carried from a pole. The bolts, 6, are insulated by means of sleeves from the support, 3, and there is no connection between the two portions of the trolley wire supported by the insulator except through the subsidiary connection, 9. On this contacts shown in the illustration by 10 are carried, and these make the connection between the trolley wire entering and leaving the insulator. It follows, then, that if a trolley wire is broken it falls down, and the circuit is broken at the contact in question. The inventor also provides extensions to the metallic brackets, 2, to which the trolley wire is attached for the purpose of making a through metallic path for the trolley wheel. The way this is done is shown in Fig. 2, which is a plan of the underside of the insulator. The material indicated by 14 is an insulator, and serves to maintain true alignment between the metallic pieces, marked 16. There is, however, no connection between these metallic extensions, except when the trolley wheel is passing over them. Alternative methods of securing this through metallic path for the trolley wheel are described. One of these involves the use of a hinged tongue piece, which is not shown in the illustration. A certain amount of flexibility is provided in connection, 9, in order that contact, 10, may always rest on the upper side of the trolley wire, independently of vibration caused by the passage of the trolley wheel. It will be seen that with this method of support the trolley wire is cut up into short sections, which are automatically cut out of circuit should a fracture occur.

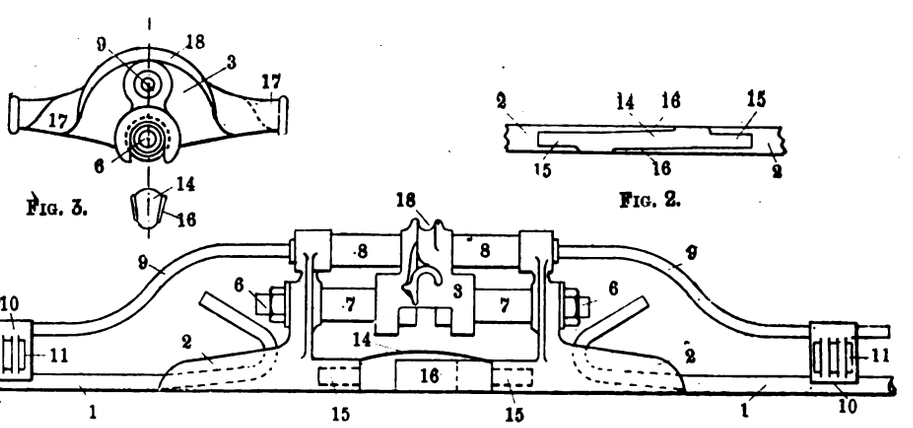

FIG. 3.

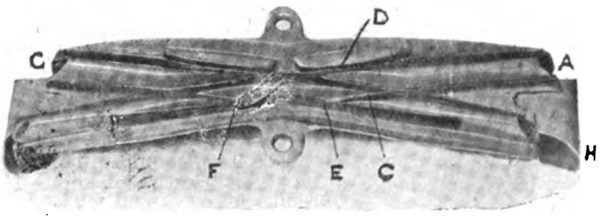
FIG. 2.

FIG. 1.—The Schierwater Trolley Wire Insulator.

### Improved Overhead Crossing.

Crossings and frogs are necessary evils on overhead tramway work, and the erratic behaviour of the trolley at these points is often the principal cause of trouble. The smaller the angle of the crossing, the greater is the liability of the trolley to take the wrong wire. If combined with a narrow-angle crossing the trolley wire is a side-running one, and there is a certain amount of overhang on the trolley wire, this trouble is still further intensified. When a trolley is advancing through a trailing frog, there is considerably more liability of damage to the overhead gear than when it is travelling in the reverse direction. Should the trolley take the wrong wire under these conditions, the mechanical frog that it would meet on this wire presents a most effective trap, and serious damage to the trolley head and overhead gear frequently ensues. On the Burton-on-Trent Corporation tramways narrow-angle crossings about 16deg. are used with a certain amount of overhang on the trolley, due to the cars not running centrally with the trolley wire round the junctions. Damage to trolleys and overhead gear has been of frequent occurrence, and, after numerous experiments, an improved design of crossing was brought out by the general manager, Mr. P. J. Pringle, and it has been the means of reducing the troubles to a negligible amount. The crossing is shown in the print herewith, and in



designing this an attempt has been made to get in practice a continuous through rail without any complicated gear or mechanism to effect it. If we presume a trolley wheel passing from A to B, there is always a possibility of it fouling the point C of the centre diamond and being thrown off the crossing. That part of the crossing marked D acts as a guard rail and prevents this occurrence, and practically gives the equivalent of a continuous rail to the passage of the trolley wheel at this point. On the trolley wheel still further advancing, the hard phosphor-bronze spring piece, E, is quite lightly sprung to one side, and then the flange of the trolley wheel meets the phosphor-bronze spring piece, F, guarding it from any possibility of taking the wrong wire. On the trolley

Digitized by Google

advancing from G to H, the same cycle of actions takes place. If a trolley head is taken in one's hand and applied to this crossing, no amount of side pressure or speed in passing across will permit of the trolley taking the wrong rail or being thrown off. All the crossings on the Burton-on-Trent Corporation tramways have been equipped with this pattern for the last six to eight months, and have proved most effective. The spring pieces are made a good length, about 7in., and are therefore quite flexible, so that the amount of wear on these due to the trolley wheel springing them open is exceedingly small, and they will have a considerable life. The replacement of them when necessary is arranged to be quite a simple matter. We understand that the British Insulated and Helsby Cables Company have taken up the manufacture of this crossing.

## Catalogues, etc, Received.

SIEMENS'S PUBLICATIONS.—From Messrs. Siemens Bros. and Co., Limited, York-mansion, York-street, Westminster, S.W., we have three new publications—viz., Price-list 6B, Price-list 3G, and Circular Y.M. 110. In the first-mentioned, carbons suitable for open-type arcs are listed in four classes—namely, marks "A," "R," "T," and "U," mark "A" being the best quality. A special class, mark "E" (which is the finest quality of carbon produced), is made for all enclosed arc lamps, and gives results which it is claimed cannot be excelled. Finally, mark "SA" is used for searchlights. Meter-testing boards are listed in the second. These should meet the demand for a standard apparatus for the rapid and methodical testing of consumers' meters. The boards are fitted with all the necessary attachments, switches, etc., for this purpose, and by which three meters can be tested at a time. They are standardised for continuous currents up to 150, 300 and single-phase meters up to 150 and 300 volts on non-inductive circuits, and for single-phase and three-phase meters up to 150 and 500 volts on inductive circuits. Testing boards for other conditions are quoted for specially. The list further contains spare instruments, compensation resistances, and various accessories, also portable apparatus for testing meters on consumers' premises. The third and last-mentioned publication briefly describes the firm's marine-type ammeter. This instrument can be used for any values of current up to 100 amperes by merely substituting a different shunt. The various sizes of shunt are supplied to give the same fall of potential for each maximum current, whilst the moving coils are all made to have the same resistance. The instrument can be fixed in any position.

BRITISH PROMETHEUS SPECIALITIES.—The latest pamphlet (No. 111) issued by the British Prometheus Company, Limited, Kingston-on-Thames, deals with electrically-heated cooking utensils and convectors of the firm's manufacture. The list includes the majority of their most popular and best selling patterns of domestic apparatus, and is intended for private circulation per the electrical trade. Several new patterns are shown, notably milk sterilizer No. 70, on p. 6, and copper shaving pot No. 780, on p. 4. We note that the company have recently opened a showroom at 27, Ely-place, Holborn-circus, E.C., where a large and representative selection of samples is on view.

COUNTRY HOUSE LIGHTING. — The "Electrical Bulletin No. 1," issued by Messrs. R. J. Nicholson and Co., 26, Cannon-street, Manchester, describes the firm's "Ideal" outfit for country house lighting. This comprises a 2-b.h.p. petrol engine direct coupled to dynamo; a storage battery capable of sustaining 13 8-c.p. lamps for five hours, or six 8-c.p. lamps for 10 hours; and a switchboard mounted with switches for charging and discharging the battery, running the lights direct off the dynamo or off the battery, together with necessary indicating instruments. Price complete, £75.

VENTILATING, WARMING, AND DRYING FANS.—James Keith and Blackman Company, Limited, 27, Farringdon-avenue, E.C., London.

## SHIPLEY ELECTRICITY ACCOUNTS.

The accounts of the Shipley electricity department for the year ended March 31, 1905, show a total expenditure on capital account to that date of £56,250. Abstracts of the general balance-sheet and revenue account, together with the statement of electricity generated, sold, etc., are appended.

GENERAL BALANCE SHEET.

| Dr. Liabilities. | £ | s. | d. |
|---|---|---|---|
| Capital account—amount received | 60,500 | 0 | 0 |
| Sundry creditors | 110 | 1 | 8 |
| Sinking fund account | 786 | 12 | 6 |
| Amount set aside for loan redemption | 2,000 | 0 | 0 |
| Amount credited to electricity revenue account | 2,683 | 10 | 9 |
| | £66,080 | 4 | 11 |

| Cr. Assets. | £ | s. | d. |
|---|---|---|---|
| Capital account—amount expended for works | 56,250 | 9 | 9 |
| Sundry debtors for current supplied | 2,793 | 12 | 5 |
| Loans repaid by means of sinking fund | 2,000 | 0 | 0 |
| Cash with treasurer and in hand | 5,036 | 2 | 9 |
| | £66,080 | 4 | 11 |

| Dr. REVENUE ACCOUNT. | £ | s. | d. |
|---|---|---|---|
| To generation of electricity | 2,613 | 12 | 9 |
| Distribution of electricity | 1,051 | 10 | 11 |
| Rents, rates, taxes, and insurance | 109 | 5 | 2 |
| Management expenses, salaries, etc. | 535 | 2 | 4 |
| | 4,309 | 11 | 2 |
| Amount carried to net revenue account | 3,054 | 5 | 9 |
| Balance to provide for bad debts | 562 | 1 | 7 |

| By sale of current by meter | 7,011 | 8 | 4 |
| Rental of meters and other apparatus | 326 | 7 | 11 |
| Public lighting | 600 | 0 | 0 |
| Sale and repairs of lamps, etc. | 264 | 18 | 2 |
| | 8,202 | 14 | 5 |
| Less discounts and allowances | 276 | 15 | 11 |
| | £7,925 | 18 | 6 |

STATEMENT OF ELECTRICITY GENERATED, SOLD, ETC.

| | | | |
|---|---|---|---|
| Quantity generated in B.T.U. | | | 1,258,371 |
| Quantity sold | Public lamps | 58,733 | |
| | Traction | 511,774 | 997,100 |
| | Private consumers by meter | 426,593 | |
| Quantity used on works | | | 148,986 |
| Total quantity accounted for | | | 1,146,086 |
| Quantity not accounted for | | | 112,285 |
| Number of public lamps (arc) | | | 40 |
| Total maximum supply demanded (kilowatts) | | | 622 |

## BURNLEY TRAMWAYS.

The following is an abstract of the revenue account for the year ended March 31, 1905, just issued by the Burnley tramways department. The capital expenditure to date amounts to £185,787.

| Dr. *Expenditure.* | £ | s. | d. |
|---|---|---|---|
| Traffic expenses—wages, cleaning, etc. | 14,449 | 11 | 4 |
| General expenses—salaries, rents, rates, etc. | 4,374 | 12 | 7 |
| General repairs and maintenance | 6,229 | 13 | 1 |
| Power expenses—cost of current, etc. | 15,449 | 0 | 9 |
| Total amount of working expenses | 40,502 | 17 | 9 |
| Munns depôt suspense account | 178 | 11 | 1 |
| | 40,681 | 8 | 10 |
| Balance carried to net revenue account | 13,345 | 4 | 9 |
| | £54,026 | 13 | 7 |

| Cr. *Income.* | £ | s. | d. |
|---|---|---|---|
| Passenger receipts | 53,497 | 17 | 6 |
| Parcel receipts | 482 | 13 | 7 |
| Advertising on time-tables | 46 | 2 | 6 |
| | £54,026 | 13 | 7 |

## FORTHCOMING EVENTS.

WEDNESDAY, JUNE 14.

**Chemical Society.**—At 5.30 p.m., general meeting.

THURSDAY, JUNE 15.

**Civil and Mechanical Engineers' Society.**—At 2.30 p.m., visit to the South-Western Railway Company's Works, Nine Elms.

FRIDAY, JUNE 16.

**Physical Society.**—"The Ratio between the Mean Spherical and Mean Horizontal Candle-power of Incandescent Lamps," by Dr. J. A. Fleming; "The Electrical Conductivity of Flames," by Dr. H. A. Wilson; "Contact with Dielectrics," by Mr. R. Appleyard; "The Pendulum Accelerometer, an Instrument for the Direct Measurement and Recording of Acceleration," by Mr. F. Lanchester; "A New Form of Pyrometer," by Mr. N. V. Stanford; and an exhibition of a refractometer by Mr. R. Appleyard.

**Dynamicables.**—Dinner at the Trocadero, June 27.

**Electrical Contractors' Association.**—Dinner at the Holborn Restaurant, June 27.

**Incorporated Municipal Electrical Association.**—June 27-30, annual convention.

**Municipal and County Club.**—House dinner (W. H. Grenfell, Esq., M.P., principal guest), June 29.

## CITY OF WESTMINSTER.

### Electricity v. Gas for Street-Lighting.

The following report by the city engineer of Westminster, Mr. J. W. Bradley, M.I.C.E., to the Works Committee gives useful figures as to the cost of street-lighting within the city. The report is dated May 27, 1905, and reads:

I beg to submit the following particulars, according to your instruction of April 13, with reference to the lighting of St. James's, as reported to you on May 23, including the further extended details as directed at your last meeting. As this instruction practically takes the form of eight questions, I propose to deal with the matter in a categorical manner.

*No.* 1. *Whole Cost at Present of Electric Lighting in the City.*—The cost of electric lighting in the city of Westminster for last year was £27,024. 10s. 1d, made up as follows:

| | £ | s. | d. |
|---|---|---|---|
| Charing Cross and Strand, etc., Company | £3,444 | 0 | 6 |
| St. James's and Pall Mall Company | 1,993 | 9 | 0 |
| Westminster Electric Supply Company | 21,587 | 0 | 7 |
| | £27,024 | 10 | 1 |

The details as to the number and rate per lamp are as follows:

*St. George's Lighting.*

| | | £ | s. | d. |
|---|---|---|---|---|
| Westminster Electric Supply Company— | | | | |
| 954 arc lamps at £22 | £20,988 0 0 | | | |
| 2 incandescent lamps at £6 | 12 0 0 | | | |
| 26 incandescent lamps at £4. 10s. | 117 0 0 | | | |
| 147 incandescent lamps at £4 | 588 0 0 | | | |
| | | 21,705 | 0 | 0 |

*St. Martin's and Strand.*

| | | | | |
|---|---|---|---|---|
| Charing Cross and Strand Electricity Supply Company— | | | | |
| 101 arc lamps at £28 | 2,828 0 0 | | | |
| 22 arc lamps at £27. 10s. | 605 0 0 | | | |
| | | 3,433 | 0 | 0 |

*St. James's Lighting.*

| | | | | |
|---|---|---|---|---|
| St. James's and Pall Mall Electric Light Company— | | | | |
| 65 arc lamps at £30 | 1,950 0 0 | | | |
| 1 arc lamp at £27. 10s. | 27 10 0 | | | |
| | | 1,977 | 10 | 0 |
| | | £27,115 | 10 | 0 |

NOTE.—The Westminster Electric Supply Company have to allow a cumulative rebate of ½ per cent. per annum, which now stands at 1½ per cent.

*No.* 2. *What would be the Cost of Lighting of equal volume by Gas?*—This question is rather a difficult one to answer with any exactitude, as it depends on the prices which may be quoted from time to time by the gas company, who have the monopoly of the supply of gas illuminant within the city area; but on the basis of tenders recently submitted by them and accepted by your Council for lighting small areas in the city, the cost would be, say, about 1,300–700-c.p. gas lamps at about £17 per annum, or about £23,000 to £25,000.

[The present number of gas lamps in the city are given in a schedule, there being some 3,038 lamps, costing £13,089. 15s. 1d. per annum]

Your reference further asks for the cost of 66 lamps in St. James's if gas, and the cost of 66 lamps if electricity, showing the difference between the two for five years and indefinite period. I presume in this question that the costs are to be based on the present tenders of the St. James's and Pall Mall Electric Lighting Company and the Gaslight and Coke Company; that being so, the comparative statement is as follows:

| | £ | s. | d. |
|---|---|---|---|
| Electricity—66 lamps at £17 | £1,122 | 0 | 0 |
| Gas—66 lamps at £15. 1s. | 993 | 6 | 0 |
| Gas—cost of alteration of existing columns for gas lighting purposes—66 lamps at £10 per lamp. Spread over five years—£2 per lamp per annum | 132 | 0 | 0 |
| Total cost per annum (first five years) | £1,125 | 6 | 0 |

NOTE.—The gas company's quotation is subject to an increase or decrease of 9s. 6d. per lamp for every 1d. per 1,000 cubic feet increase or decrease in price of gas, which is now charged at 2s. 2d. per 1,000 cubic feet. The variation of each 1d. will mean an increase or decrease of £31. 7s. per annum on the above figures.

At the end of five years, should the Gaslight and Coke Company be open to continue the annual charge for maintenance at the rates now quoted, the cost per annum for these 66 lamps would amount to £993. 6s.

As I have also been instructed to include in this report a comparative statement of the annual cost which would be incurred if all the streets in the city were illuminated with electricity or gas, I have to report that on an average of 30 lamps per mile the cost of lighting would be as follows:

| | Per annum. £ | s. | d. |
|---|---|---|---|
| St. James's and Pall Mall Company's basis at £17 per lamp | £51,000 | 0 | 0 |
| Scott Snell Self-Intensifying Gas Company's basis at £17 per lamp, as erected in Whitehall | 51,000 | 0 | 0 |
| Gaslight and Coke Company's present basis of £15. 0s. 11d. per lamp, as erected in Aldwych (a reduction on the original tender, consequent upon the reduced price of gas) | 45,137 | 10 | 0 |
| Gaslight and Coke Company's basis including cost of erection of standard spread over five years | 57,137 | 10 | 0 |
| Gaslight and Coke Company's present tender for 66 lamps in St. James's, including cost of conversion, spread over next five years | 51,150 | 0 | 0 |
| Gaslight and Coke Company at the end of five years, if the gas company undertook the lighting for a further period at the present figure quoted by them for 66 lamps in St. James's—viz., £15. 1s. | 45,150 | 0 | 0 |
| The present annual cost of street-lighting (gas and electric) in the city of Westminster | 41,000 | 0 | 0 |

*No.* 3. *Advantages of Lighting by Gas and by Electricity from the City Engineer's Point of View*—Originally, when gas was used through the medium of flat-flame burners for the purposes of lighting shop thoroughfares, electricity was held to have certain advantages owing to the fact that the light as produced by the burning of coal gas through flat-flame burners was very yellow in character, and it was difficult to ascertain the colour of materials and goods in such light. Owing, however, to the introduction of incandescent mantles, the light as now given by gas illumination is, from a colour point of view, practically the same as that of an ordinary electric arc, there being very little difference.

*No* 4. *Relative Penetrability of Gas Lighting and Electric Lighting in Case of Fog*—There is no doubt that the yellow light of the flat-flame burner has a better penetrative effect in times of fog than the whitish-blue of the electric arc, but as between the ordinary electric arc and incandescent gas there is very little difference in their fog penetrative qualities. It is now possible to obtain carbons which give a yellow light, and by using these electric arc lamps would have a much better penetrative effect in times of fog than the ordinary incandescent gas lamp.

*No.* 5. *Whether in "Big Shop" Thoroughfares like Regent-street, Piccadilly, etc., Gas Lighting would be as advantageous as Electric Lighting, and whether the use of Electric Light in certain streets would benefit trade?*—As may be gathered from the replies to queries 3 and 4, there is little difference between incandescent gas lighting and electric in this point. One point in favour of electric light is that it can be turned on and off so quickly as compared with gas lighting.

*No.* 6. *Cost of Lighting such Streets by Gas and Cost by Electricity.*—The cost of lighting streets by gas and by electricity for *equal volumes of light* may on the basis of recent competitive quotations be taken roughly as about 8 is to 9, as referred to in my reply to query 2. While, however, there is competition between electricity supply companies, the gas company have the monopoly of gas supply.

*No* 7. *The Practicability of a System for Lighting "Big Shop" Thoroughfares with Electricity and Remaining Streets with Gas.*—There would be no difficulty in lighting one class of thoroughfare, or shop thoroughfares, with electricity and the remaining streets with gas.

*No.* 8. *Regard to be had to Existing Contracts for Lighting*—The existing contracts for lighting are as follows: Westminster Electric Supply Corporation for lighting St. George's district, terminating Aug. 26, 1930; Charing Cross, City, and West End Electricity Supply Corporation for lighting St. Martin's district, terminating Sept. 17, 1920, but determinable at end of seven or 14 years from the year 1899; St. James's and Pall Mall Electric Lighting Company's contract for lighting St. James's district has expired; the Gaslight and Coke Company for the lamps in the Strand and St. James's areas, St. Martin, and St.

Digitized by Google

**Margaret and St. John areas, terminating Dec. 31, 1909; Gaslight and Coke Company for lamps in Aldwych and Kingsway for a period of five years; Scott Snell Self-Intensifying Company for lamps in Whitehall terminable at three months' notice.**

## PHYSICAL SOCIETY.

At the meeting of this society on May 12, Dr. C. Chree, F.R.S., vice-president, in the chair,

Prof. H. L. CALLENDAR read a paper on "*A Bolometer for the Absolute Measurement of Radiation.*" It is now generally agreed that the electric compensation method, in which the heat received by radiation on a metallic strip is determined by measuring the electric current required to produce the same rise of temperature in the strip, is the most satisfactory and accurate method for absolute measurement. Two methods have been used for this purpose: (1) the thermo-electric method of Angström, in which the equality of temperature between the strip exposed to radiation and that heated by the current is determined by means of a copper-constantan couple, the two junctions of which are attached to the backs of the two strips with silk paper and shellac; (2) the bolometric method of Kurlbaum, in which the rise of temperature produced by the radiation or by the electric current is measured by the increase of resistance of the metallic strip itself. In applying the first method it is necessary to use a sensitive galvanometer for the thermo-couple, and an accurate milliammeter for the current. It is also necessary to make measurements with the strips interchanged, as it is impossible to secure exact equality of resistance of strips and exact quality of thermal contact for the junctions which are insulated from the strips by paper and shellac. The advantages of the second method, which has not hitherto been applied to the extent which it merits, are (1) that the strip is also the thermometer, and can, therefore, be made much thinner and quicker in action, as no paper insulation is required; that the power available is much greater, so that the same portable milliammeter which serves for measuring the current may also be used for the resistance balance in place of a sensitive galvanometer; (3) that the actual resistance of the strip may readily be verified at the time without special additional apparatus; (4) that uniformity of resistance of the strip is less important than in the thermo-electric method, in which the mean resistance of the strip is not necessarily the same as the resistance at the central point where the temperature is taken by the couples; (5) that the area exposed to radiation may be more accurately measured. In the practical application of the bolometric method for the absolute measurements of solar radiation, the author has introduced certain modifications suggested by experience in platinum thermometry, with the object of securing (1) temperature compensation, so that the zero remains constant in spite of changes in the surrounding temperature; (2) conduction compensation, so that loss of heat by conduction at the ends of the strips may not affect the readings; (3) accurate measurement of the area of radiation absorbed. (1) In order to secure accurate temperature compensation during the observations of radiation, when changes of temperature of the instrument are sometimes unavoidable, especially with powerful sources of radiation, in spite of the water-jacket in which the instrument is enclosed, the bolometer is balanced against a balancing resistance constructed of the same platinum, enclosed in the water-jacket, but protected from the radiation. (2) To secure conduction compensation, this balancing resistance is made in two parts—one (*a*) precisely similar to the bolometer itself, but with strips 1cm. long instead of 3cm., so that the ends of the strips are subject to the same conduction losses as those of the bolometer when heated by the electric current, the change of resistance measured being that of the central 2cm. only of the strips, which length is uniformly heated. The other part, *b*, of the balancing resistance is replaced by a resistance of manganin when the actual temperature of the bolometer or the heating effect of the current is measured. (3) To secure accurate measurement of the area of radiation absorbed, this area is determined by an aperture in the cover of the water-jacket having a width of 2cm. coinciding with the central portions of the bolometer strips. The strips are arranged with a small overlap, so that all the radiation entering this area falls on the strips. The necessity of accurate measurement of either the length or the width of the strips themselves is thereby avoided. With these modifications the bolometric method appears equal in convenience, and probably superior in accuracy to the thermo-electric. Owing also to the great increase in power available, the absolute measuring bolometer can be directly used with one of the author's self-recording instruments for solar radiation. Comparisons have been made between the bolometer, in which the platinum strips are directly exposed to radiation, and one of the author's ordinary sunshine receivers enclosed in a glass bulb in order to determine the effect, if any, of the glass bulb in selective absorption. The values of the reduction constant obtained for the glass receiver showed no certain variation over a wide range of quality of radiation, from sunshine or arc light down to a dull red heat. This result is probably to be attributed to a self-compensating action of the glass bulb, which radiates to the enclosed coils precisely those ray which it absorbs.

Mr. CAMPBELL pointed out that with regard to the comparison made by Prof. Callendar between the open and the glass-covered bolometers, it should be noticed that the radiation used in the experiment had already passed through the glass of the globe surrounding the glowing filament. This would filter out some part of the radiation, possibly in such a way as to make the two instruments agree more closely than they otherwise would.

Mr. PRETTY suggested that bolometers such as the author described might be used for testing the watts given out by incandescent lamps.

Prof. AYRTON wished to draw special attention to the effect to which Mr. Campbell had alluded—namely, the fact that the radiation used by the author had already been filtered by passing through glass before it reached the glass-enclosed bolometer.

Dr. CHREE enquired whether the Angström instrument was affected by lag, and to what extent?

Prof. CALLENDAR said that in his experience the Angström instrument took nearly one minute to reach within ½ per cent. of its steady reading. He had made comparisons with the naked arc as well as with the enclosed incandescent source, and found the results did not differ materially. The glass-enclosed receiver also gave consistent values of the reduction constant when compared with the Angström instrument or the bolometer, which were not screened by glass.

Mr. W. H. PRICE read a paper on the results of experiments carried out at Crompton's works at Chelmsford, by Mr. C. H. Wright, on the possibility of using the resistance of a conductor heated by an alternating electric current as a measure of the current. An alternating current was passed through a thin conductor in series with a standard resistance, and a small direct current from a storage battery superposed on the system. The mean differences of potential at the terminals enabled him to compare the resistances on a potentiometer. The presence of any considerable body of air near the heated conductor was found to affect the results through the irregular currents of air produced, while the neighbourhood of solid matter caused the permanent condition to be reached only slowly in consequence of its heat capacity. To obtain uniform results so that the resistance of the conductor corresponded consistently and promptly to the current passing, it was found necessary to enclose the conductor in a relatively large vessel exhausted of air. Nearly consistent results were then obtained, affected, however, to some extent by the changes in the vacuum by the liberation of gas occluded in the conductor. At moderately good degrees of exhaustion the resistance of the conductor for a given current varies rapidly with the quantity of gas that remains, and it was suggested that this might form the basis of a vacuum gauge. The results of experiments on carbon incandescent lamps and on platinum-foil ligaments in exhausted bulbs were shown in diagrams, giving the effects of different air temperatures and of the degrees of exhaustion. The author supposed that such conductors enclosed in large glass bulbs, highly exhausted when the conductors are incandescent, would form useful gauges for electric currents. They would be perfectly portable, not easily liable to damage, capable of highly accurate and permanent calibration, and, of course, very inexpensive. They could be made of exceedingly small inductance and capacity, and their values would be independent of periodicity and wave-form. Their employment would correspond in precision and sensitiveness to other measurements of electrical resistance. The useful range of currents measured by one such conductor might be of the order of 1 to 4.

Prof. AYRTON pointed out that at any rate for small alternating currents a suitably wound instrument of the Kelvin-balance type was quite sufficiently accurate.

Mr. CAMPBELL asked was any compensation introduced for the temperature of the walls of the enclosure, or was the temperature merely read and a correction made for it?

The AUTHOR, in his reply, said that in all cases corrections were applied for the external temperature.

---

The meeting on May 26 was held at the National Physical Laboratory by invitation of the director, Dr. Glazebrook. The laboratory was open to the inspection of Fellows, and the following special demonstrations were shown:

"*The Specific Heat of Iron at High Temperatures,*" by Dr. J. A. HARKER. A knowledge of the specific heat of iron is important in the determination of high temperatures by calorimetric methods. Dr. Harker has determined the total heat of iron up to temperatures of 900deg. C. by heating the specimen in an electric furnace, the temperature of which was determined by a resistance thermometer, and dropping the iron into a water calorimeter. A difficulty arises at high temperatures owing to the oxidation of the iron when it comes in contact with the water in the calorimeter, and it is necessary in these circumstances to enclose the specimen by a suitable shield. Quartz tubes were tried, but it was invariably found that they splintered when immersed in the calorimeter. The difficulty was overcome by having in the calorimeter a vertical cylindrical brass tube, filled with magnesia, terminating at its upper end in a hemispherical cup. The iron, in the form of a cylinder the diameter of which was slightly less than that of the tube, was dropped into the magnesia. The extreme flocculence of the powder allows the iron to go straight to the bottom of the tube, and it is thus protected from oxidation. Dr. Harker illustrated by curves some of the peculiarities of the specific heat of iron at high temperatures.

Dr. HARKER also exhibited some new types of electric furnace for the attainment in absence of noxious gases of temperatures between 800deg. C. and 2,200deg. C. The conductor conveying the electric current is a tube of solid electrolyte similar in composition to the filament of a Nernst lamp. An essential feature is that for many purposes the usefulness and life of a furnace constructed in this way may be much increased by adopting a "cascade" system of heating—that is, the energy supplied may be divided so that only sufficient is put through the tubular conductor to raise its temperature, say, 1,000deg. C. above its surrounding, the surrounding itself being maintained at 1,000deg. C., thus enabling a temperature of 2,000deg. C. to be attained in the tube without straining it unduly. The regulation of temperature in small furnaces of this type is so perfectly under control that very well defined melting points may be taken with very small quantities of substance. The thermo-electric method has been used in these furnaces for determining the melting point of platinum, the mean result of the experiments giving 1,710deg. C. ± 5deg. C.

Digitized by Google

Mr. A. CAMPBELL exhibited apparatus for the measurement of small inductances. The method of measurement is that adopted by Max Wien, and described by him in a paper on "Magnetisation by Alternating Currents" (*Wied. Ann.* (13) August, 1898). It is a modification of Maxwell's method of comparing two self-inductances, the source of voltage being alternating, and the indicating instrument a tuned optical telephone or vibration galvanometer.

In the Optical Department two new optical benches constructed for the laboratory by Messrs. R. and T. Beck were shown by Mr. SELBY. One of these is specially designed for the rapid testing of spherical and cylindrical lenses, such as are found in oculists' trial cases. The bench consists of two parallel steel bars of circular section, 14ft. long, supported on four cast-iron standards. The carriage carrying the lens-holder is moved along the bench by an endless steel tape which passes over pulleys at the ends of the bench, the movement being produced by rotation of the pulley at the eye end: the focal length of the lens is read on the tape at this end of the bench. The most novel feature in the design is the arrangement provided for rotating the lens holder from the eye end, for the determination of errors of centering of spherical lenses, and errors in the position of the axis in the case of cylindrical lenses. A triangular tube, which extends along the whole length of the bench, passes through a rotating fitting which projects from the lens-holder carriage. By means of gut belting and a spring pulley, rotation of the triangular tube is transmitted to the lens-holder.

The second bench is designed for the determination of the loss of light by absorption and reflection in telescopes and binoculars. The carriages with the various parts of the apparatus move on rollers along the bench. A parallel beam of light from a collimator passes through the telescope adjusted for infinity, and a lens interposed forms an image of definite size of the aperture of the telescope objective on the screen of a photometer, where the illumination can be compared with that from a standard source. Comparative measurements can in this way be made: for an absolute measurement the magnifying lens is omitted, and two similar telescopes, or the two halves of a binocular, are set back to back. The light then transmitted is compared with that which passes through an aperture of the same size as the object glasses of the telescopes when the telescopes are removed.

# LEGAL INTELLIGENCE.

## OVERCROWDING.

At Wood Green Police Court, Wm. Vickery, electric tram conductor, was summoned for carrying 20 passengers more than the authorised number.

Mr. Muskett prosecuted on behalf of the Commissioner of Police and Mr. Godfrey defended on behalf of the electric tramway company.

Defendant pleaded not guilty.

A police-constable deposed that on Easter Monday the defendant's car was overcrowded, in consequence of which he stopped it. Witness said, "You have a tidy few over your number," and defendant shouted out, "All who have not got tickets leave the car." Twenty passengers got out. When told that he would be reported, defendant said, "We'll see about that."

Cross-examined: Defendant could easily have stopped the bank holiday crowd from getting on the car. Plenty of cars passed him which were not carrying excess passengers.

The CLERK: If the conductor had difficulty in getting them off he could have kept his car stationary, and, moreover, could have prosecuted them?

WITNESS added that defendant could have put a guard across the entrance to keep people out.

Mr. GODFREY said that the Act under which the summons was taken was passed when stage coaches ran, and it was not thought at that time that bank holidays and electric traction would be invented—two things which absolutely made that law impossible to comply with. It was impossible to cope with the bank holiday crowd except by the reasonable method adopted by the police—viz., by allowing the trams to carry away people as quickly as possible. Another thing of late years was football, and there, again, the police could do nothing beyond getting people away as fast as they possibly could after the matches were over. In order to get over the difficulty, numerous corporations over the country which were running their trams had passed by-laws—Croydon had also done so—whereby on such occasions the number of passengers was not limited.

Mr. MUSKETT: Then they are bad, because they are repugnant to the law of the land.

Mr. GODFREY: We are doing what we can to study the interests of the public. Under the new Metropolitan Electric Act of this year, which was unopposed, and which would go through in about a month's time, there was a clause which would enable them to make a by-law. He asked the Bench to take into consideration the very different state of traffic in London to-day compared with 1842, when the Bill was passed.

The magistrates, after brief consideration, came to the conclusion that there must be a conviction. Having regard, however, to the extenuating circumstances, the nominal fine of 20s. and costs would be imposed.

## GUARANTEE OF AN ELECTRIC MOTOR.

In the City of London Court, before his Honour Judge Lumley Smith, K.C., an action was brought by Mr. Arno Edler, 17, Appold-street, Finsbury, to recover the sum of £94. 11s. from Messrs. Adams Bros., 59, Moor-lane, for an electric motor supplied to their order.

Mr. R. J. COLAM, plaintiff's counsel, said the defendants had until July last year driven their machinery by a large gas-engine. They had had an electric motor for auxiliary purposes, but just prior to July 15 they had an interview with the plaintiff, who was asked to supply a small motor of 2½ h.p., which the defendants said they wanted to enable them to work their machinery overtime. The plaintiff suggested that the defendants should have a separate motor for each separate machine, to obviate transmission losses. As this did not suit the defendants, the plaintiff suggested that the defendants should have two motors, one for each floor. Ultimately a motor was supplied, and the question for the Court to decide was whether there was an implied condition that it was fit for some specific purpose which the defendants mentioned to the plaintiff. Their case was that the motor would do all they had promised.

Mr. GOVER, for the defendants, said they told the plaintiff the purpose for which the motor was required, and it was absolutely useless.

Mr. COLAM said the whole question turned upon whether the motor was strong enough to drive the defendants' machines.

According to the plaintiff, the defendants stated that they wanted a 15-h.p. motor, but when the motor was fixed up it was worked up to 25 h.p., and blew the fuses. The defendants had expert advice as to whether the machines would be suitable or not for their purpose. It was not true that the plaintiff had ever said that a 15-h.p. motor would be sufficient to drive the whole of the defendants' machinery. It was supposed that they would use it for one or two machines at a time, and not for the whole eight.

For the defence Mr. ADAMS said the motor for which the plaintiff was suing was quite useless for the purpose for which it was required. He expected a motor to drive the machines in the basement, and if he did not want to run the basement, then he expected the motor to be able to drive the next floor or the second floor. As a matter of fact, the motor would not turn the shafting round.

Judge LUMLEY SMITH, in giving judgment, said it was true the motor had been fixed on the first floor, because the defendants requested it. The defendants set up the plea that there was a guarantee that the motor would drive all their machinery, or that it would do certain work. The defendants further relied upon Section 14 of the Sale of Goods Act. It was not made out to his satisfaction that the buyers had relied upon the seller's skill or judgment. He did not think there was any guarantee by the plaintiff that the motor would do any particular work. Consequently judgment must be given for the plaintiff on the claim for £94. 11s., as well as on the counterclaim, with costs.

## PRODUCTION OF TRAMWAY TICKETS.

John Wilkinson again appeared at the Bradford City Police Court last week to answer a summons for failing to show his ticket on an electric car when required to do so. The case was reported in our last week's issue. The Stipendary Magistrate said the case was an extremely clear one so far as he could read the law. There was a great distinction between the Sheffield case and the present one. In the case heard by the Lord Chief Justice and his colleagues the facts were different from this one. In that case the ticket never got into the hands of the person charged; it fell on the floor, not having come into the person's hands. The Lord Chief Justice said the man was not bound to touch the ticket. In the present case the defendant took a ticket and threw it on to the floor. He might just as well have thrown it into the street. In throwing it upon the floor he refused to produce it when requested to do so, and the inspector was not obliged to go on to the floor to get it any more than he would have been obliged to go out into the street for it. Defendant would be fined 5s. and 13s. costs.

# COMPANIES' MEETINGS AND REPORTS.

## UNITED ELECTRIC TRAMWAYS OF MONTE VIDEO.

The general meeting of this Company was held at Winchester House on Monday, Mr. William Trotter presiding. In moving the adoption of the report he stated that the result of the working of the tramway systems showed a decrease of 12,560dol. This decrease was due to the revolution which broke out early in 1904, and continued until September. The first six months of the current year had, however, shown increased receipts of £4,481, the total being an amount which exceeded the previous best six months by over £1,000. He also explained the concession obtained by the Company, which was for 75 years certain, but might be extended under certain conditions to 90 years. The municipality for the concession received £9,000, and would take 3 per cent. of the gross earnings of the Company for the first 25 years and 3½ per cent. afterwards. The report and interim dividend on the preference shares at the rate of 6 per cent. per annum were approved.

## ORIENTAL TELEPHONE AND ELECTRIC.

An extraordinary general meeting was held last week at the Great Eastern Hotel.

Sir AUCKLAND COLVIN presided, and moved a resolution for empowering the directors to create debenture stock to the extent of £200,000 and to issue the same from time to time as they might deem expedient. He reminded the shareholders that at the last annual meeting he stated that additional capital would be required in the near future in order to meet expenditure on underground cables and for other similar purposes. It was found that a considerable sum would be wanted within the next few months, and the Board had been advised that it would be better to make the issue before the autumn holidays commenced. They had considered it desirable, in the interests of the shareholders, to create the proposed debenture stock rather than issue the remaining £50,000 of 6 per cent. preferential shares,

Digitized by Google

which they had power to do. It would be a much smaller charge upon the revenue, and would carry with it its own sinking fund. The amount which they took powers to create might seem unnecessarily large, but it was thought advisable to fix the sum at £200,000 in view of the possibilities of the Company in the future, for they must remember, supposing it became necessary hereafter to create second debenture stock, that such stock would not be so valuable as one having a first charge on the total assets, and it would naturally be issued under less favourable conditions.

The resolution was unanimously carried.

## WEST AFRICAN TELEGRAPH.

The annual meeting of this Company was held last week at Electra House, London, the Marquis of Tweeddale presiding. Particulars of the report appeared in our issue of the 26th ult.

The CHAIRMAN, after reviewing the financial position, stated that the liability of the Company to maintain certain cables on the West Coast of Africa, in accordance with the arrangement entered into with the French Government in February, 1902, expired in September last, and in regard to these cables no expenses in respect of maintenance would have to be provided by the Company in future. All things considered, he thought the report would be regarded as satisfactory.

The report was adopted unanimously.

## PULFORD BROS., LIMITED.

The seventh annual meeting of shareholders of Pulford Bros., Limited, was held at Liverpool on the 31st ult.

Mr. E. G. PULFORD, who was elected chairman, reported that the year's trading had been most successful. They had completed some large contracts, and had commenced the new year with a considerable amount of work, and the prospects of the Company were of the brightest.

It was proposed by Mr. J. CARGILL, and carried unanimously, that a dividend of 20 per cent., free of income tax, be paid for the year ended March 31 last, and that the balance of profit be carried to reserve fund, raising this fund to 20 per cent. of the capital.

Mr. Theo. S. Sheard was unanimously re-elected auditor for the ensuing year.

A vote of thanks to the chairman concluded the meeting.

## BABCOCK AND WILCOX.

The directors have issued circulars calling an extraordinary general meeting for the 15th inst. to consider suggested modifications in the reserve fund and capital account. It is proposed to make a distribution out of the reserve fund of £265,000, at the rate of 10s. per share to the holders of ordinary shares whose names appear upon the register of members on June 22, while at the same time 265,000 ordinary shares of £1 each will be offered to the shareholders at par in the proportion of one new share for every two ordinary shares held. In order to carry through this scheme it is intended to create 270,000 new £1 ordinary shares.

## SUNDERLAND DISTRICT ELECTRIC TRAMWAYS.

The report for the year ended March 31 last states that during the year the work of construction of this Company's tramways has been proceeded with, and it is now anticipated that the first section will commence operating about the date of the meeting. The construction of the line has been unavoidably delayed by protracted negotiations in connection with road widenings, but nearly all the difficulties in connection with these have been practically overcome. The power station is in course of erection, and is nearly completed. It is expected that the second section of the tramways from Houghton-le-Spring to South Hetton will shortly be constructed, the Company having made financial arrangements to meet the outlay upon the construction of this section, and a large amount of the calls in arrear at the date of the balance-sheet having been since collected. The directors have entered into a contract with the Durham Collieries Electric Power Company, Limited, whereby that company operates under rent and royalty the right to supply electric light and power in the district covered by this Company's orders, and, at the same time, they have further arranged with the Durham Collieries Electric Power Company, Limited, to supply the Sunderland District Tramways, Limited, with the power necessary for driving their electric plant for the operation of the tramways.

The ordinary general meeting was held last week, when Sir RILEY LORD, who presided, reviewed the position in detail and predicted a bright future.

The report was unanimously adopted.

## NEW COMPANIES REGISTERED.

**Everett, Edgcumbe, and Co., Limited.**—Capital, £20,000 (4,000 preference, 15,997 ordinary, and three "A"). Object: to acquire and carry on the business of mechanical and electrical engineers carried on at Hendon, and at 87, Victoria-street, Westminster, as Everett, Edgcumbe, and Co.

### Liens Registered.

**Potteries Electric Traction Company, Limited.**—Particulars of a series of debentures, securing half the amount of the subscribed capital, authorised by resolutions of March 28, 1900, and May 11, 1905, have been filed, pursuant to Section 14 (4) of the Companies Act, 1900. The subscribed capital at date of last return was £489,990. Property charged: the company's undertaking and general assets, present and future. There are no trustees for the debenture holders, but the debentures are issued to trustees for holders of debenture stock acting under a trust deed, dated July 26, 1900. Some of the debentures of this series have already been registered.

**North Wales Power and Traction Company, Limited, London, E.C.**—Trust deed registered May 23, for £135,000 debenture stock. Trustees: London and New York Investment Corporation, Limited; charged on the undertaking, and all the property, assets, and rights, present and future, except the uncalled or unpaid capital.

## PERSONAL.

Mr. Charles Lill has resigned his position as manager of the electrical department of Messrs. Penrose and Co., and accepted the appointment of technical manager in the power department of the Armorduct Manufacturing Company, Limited, Farringdon-avenue, London, E.C.

The Southport Tramways Committee have decided to recommend the Council to advance the salary of Mr. J. T. Kendrew, the tramways manager, from £200 to £225, dating from April 1 last, afterwards advancing by two annual increments of £12. 10s. to £250.

The Sheffield Corporation have presented James Mitchell, until recently motorman in the Corporation's tramway service, with a handsome dressing case on the occasion of his leaving the Corporation after 14 years' service; and Mr. William H. Martin, for over four years a ticket inspector in the municipal service, with a beautiful marble clock as a mark of their esteem on his retirement from the staff.

The Rochdale Town Council have increased the salary of Mr. C. C. Atchison, the borough electrical engineer, by £50, making his remuneration £350 per annum.

Mr. J. Willoughby Meares, who was for some time an electrical engineer at Llanelly, has been appointed electrical adviser to the Government of India, a post only now established, and which he will be the first to fill.

The West Hartlepool Town Council have increased the salary of Mr. H. F. Friederichs by £25 per annum.

## APPOINTMENTS VACANT.

**Assistant Borough Electrical Engineer,** Poplar. Salary, £200 per annum, rising by annual increments of £10 to a maximum of £300 per annum. Applications by June 14.

**Junior Engineer,** Dundee Electricity Department. Applications to H. Richardson, A.M.I.E.E., general manager and engineer.

**Draughtsman,** Trowbridge. Salary, £100 per annum. Applications to Mr. R. W. Merriman, County Offices, Trowbridge, by June 10.

**Various.**—Northampton Institute, St. John-street-road, London, E.C. Mechanical engineering department: drawing office and lecture assistant, full time, £120; pattern maker and instructor in pattern making, full time, £120; junior drawing office instructor, full time, £100; laboratory demonstrator for the engineering laboratories, full time; junior technical assistant, full time; evening instructor in automobile work, two evenings per week. Electrical engineering department: junior technical assistant, full time; junior lecture assistant, full time. Applications by June 29. See advertisement.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Ghent.**—The Harbour Authorities require tenders for three electrical lifts. Tenders by July 17.

**Panama.**—The Municipality will shortly require tenders for construction of an electric tramway.

**Hornsey.**—The Town Council invite tenders for switchboards and brackets for arc lamps. Tenders by June 19.

**Darlington.**—The Corporation invite tenders for switchboard extension and booster. Tenders by June 19.

**Aston Manor.**—The Corporation invite tenders for the electrical equipment of their overhead tramways. Tenders by June 23.

**Grays Thurrock.**—The Urban District Council invite tenders for switchboard extension, storage battery, etc. Tenders by June 17.

**Leigh (Lancs.).**—Tenders are invited for the supply of one water-tube boiler for the electricity department. Tenders by July 1. See advertisement.

**Rosario de Santa Fe Argentine.**—The Municipality require tenders for the construction and working of electric tramways in the town. Tenders by July 30.

**Cardiff.**—The Asylum Visiting Committee invite tenders for the electric lighting of their new asylum at Whitchurch. Tenders by June 14. See advertisement.

**Madrid.**—The Public Works Department invite competitive schemes for making a tramway for passenger and goods traffic from Brezo to Santuario de la Yedra by June 22.

**Kingston-upon-Hull.**—The Electric Lighting Committee invite tenders for the supply, delivery, and erection of various plant. Tenders by June 22. See advertisement.

**Liria.**—The Municipality require tenders for installation of electric lighting; 2,000 c.p. are required for street-lighting, for which it is proposed to pay 6,000 pesetas per annum.

Digitized by Google

**Manchester.**—The Electricity Committee invite tenders for the supply of low-tension cables, ampere-hour and watt hour meters, and box compound. Tenders by 10 a.m. on 14th inst.

**Brussels.**—The Belgian Government Railways require tenders for a number of lamps and accessories. Specification No. 97 may be obtained from their office at Brussels. Tenders by June 14.

**Laventhem (Belgium).**—The Municipality require tenders for erection of central station, laying of mains, etc. Particulars (3s. 4d.) may be obtained from the Secretary of the Mayor of that place.

**Bristol.**—Tenders are invited for single-phase alternating-current transformers and three-phase to direct-current motor-generators. Full particulars from the City Electrical Engineer, Temple Backs, Bristol.

**Stalybridge.**—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

**Lugano (Switzerland).**—Tenders are invited for the erection of an electric power station at Zordola, to be worked by water power. Particulars may be obtained from the town clerk. Tenders by June 9.

**Ossett (Yorks).**—The Town Council invite tenders for the following plant: (Section No. 1) quick-speed engines for direct coupling to dynamos; (2) dynamos, boosters, and balancers; (3) storage battery; 4) switchboard; (5) travelling crane; (6) cables. Tenders by June 14.

**Switzerland.**—M. R. Vontobel, of Winterthour, and M. Charles Probst, of Lucerne, have obtained a concession for the construction of a narrow-gauge electric railway from Meiringen to Gletsch. The total cost of the enterprise is estimated at £241,600; £19,600 is to be expended on rolling-stock.

**Esh (Durham).**—Tenders are invited for erection of electric lighting plant on the road leading from Cornsay Lodge by Commercial-street, Cornsay Colliery, and then by the low road to Hausteels crossing, being a distance of about 1,600 yards. Tenders to the Esh Parish Council by June 13.

**Glasgow.**—The Corporation invite tenders for the construction of tramway in Dalmarnock-street and Springfield-road from Great Eastern-road to Dalmarnock-road. Specification, etc., can be had on application to Mr. James Dalrymple, general manager, 46, Bath-street, Glasgow. Tenders by 10 a.m. on June 13.

**London, W.**—The Great Western Railway Company invite tenders for the supply, delivery, and erection of the following plant in connection with their electricity generating station at Park Royal: (Specification 18) pipework, feed and other pumps, tanks, feed heaters, water-softening and oil-separating plant, etc. Tenders by 10 a.m. on 26th inst.

## RESULTS OF TENDERS.

**London County Council.**—The following tenders have been recommended for acceptance: Dick, Kerr, and Co., induction motor-generators (5), £8,850; H. Lovatt, Limited, erection of boundary wall, Greenwich electricity station, £2,800.

**Birmingham.**—The Corporation have accepted the tender of Bolckow, Vaughan, and Co., Limited, Cleveland Steelworks, Middlesbrough, for the supply of 1,650 tons of steel rails and fishplates for the electric tramways, the contract price of the rails being £5. 10s. per ton.

**Brighton.**—The Town Council have accepted the offer of the British Westinghouse Electric and Manufacturing Company to supply and fix additional switchgear required at the North-road station for £690, and their offer to supply isolating switches to all existing feeders and accessories at the generating station at Southwick for £1,450.

**Heywood (Lancs.).**—The Corporation have accepted the following tenders for the supply, erection, and completion of electrical plant and tramway work: T. Hill and Sons, Victoria Ironworks, Heywood (Section A) boiler; Dick, Kerr, and Co., Abchurch-yard, Cannon-street, London, E.C. (B), engines, etc.; Ferranti, Hollinwood (C), switchboards; British Insulated and Helsby Cables, Prescot (D), cables; R. W. Blackwell, 59, City-road, London, E.C., permanent way (Sections A and B). Total, £29,393.

**Sutton (Surrey).**—The following tenders have been received for the proposed telephone exchange at Sutton, for H.M. Office of Works, etc.:

| | |
|---|---|
| A. N. Coles | £1,155 |
| Gathercole Bros. | 1,200 |
| H. M. Patrick | 1,207 |
| Martin, Wells, and Co., Limited | 1,220 |
| Smith and Sons | 1,238 |
| W. H. Lorden | 1,259 |
| R. Dean and Co. | 1,260 |
| E. M. Bulled and Co. | 1,273 |
| Higgs and Outhwaite | 1,275 |
| J. B. Potter | 1,276 |
| F. J. Shopland | 1,277 |
| F. G. Lawrence | 1,288 |
| Enness Bros. | 1,292 |
| J. Smith and Sons, Limited | 1,298 |
| Banyard and Son | 1,300 |
| E. Streather | 1,354 |
| C. Ansell | 1,387 |

**Fulham.**—The following tenders are recommended for acceptance: Redpath, Brown, and Co., for construction of steel roof and coal bunkers at the electricity works, £2,442. 13s. 2d.; General Electric Company, for 100 3-ampere meters £187. 10s., 50 10-ampere ditto £98. 15s.; British Thomson-Houston Company, for 100 5-ampere meters £187. 10s., 25 30-ampere ditto £50, 10 50-ampere ditto £24. 6s. 8d., 10 75-ampere ditto £28. 6s. 8d., and 5 100-ampere ditto £15. 16s. 8d.; E. Green and Son, for removing the existing economisers and constructing two new economisers, £624. Messrs. Windsor and Co. have been approved as sub-contractors for the construction of foundations, and other work in connection with the contracts of the Stirling Boiler Company for boilers, and of E. Green and Sons for economisers.

# BUSINESS NOTES.

## TRACTION.

**Warsington.**—The trams show a profit on the past year of £450.

**Dover.**—The extension to River is proceeding apace, and may be completed within a couple of months.

**Derby.**—The work in connection with the construction of the electric tramways on the Kedleston-road has been commenced.

**Leith.**—The Corporation have asked the Board of Trade to inspect the new lines from Pilrig to Newhaven, so that a temporary service of tramcars may be run.

**South Shields.**—A commencement has been made with the work of constructing the tramways, which are expected to be completed before the end of October.

**Epping Forest.**—On Saturday the first electric tramway to Epping Forest was inaugurated. By means of the line the forest is brought into close touch with suburban Essex.

**Queensferry.**—At a special meeting of the Town Council the draft provisional order to incorporate a company to construct an electric tramway from Edinburgh to Queensferry was approved.

**Light Railways.**—A Board of Trade return issued on Tuesday shows that between 1896 and 1904 234 orders were confirmed under the Light Railways Act, representing a mileage of 1,552, and an estimated expenditure of £11,279,780.

**Rotherham.**—At the meeting of the Borough Council on Tuesday the chairman of the Tramways Committee intimated that they were still open to negotiate for through running with Sheffield if the latter would meet them in a reasonable spirit.

**Dewsbury.**—Major Druitt, on behalf of the Board of Trade, has held an enquiry relative to the proposal to pave certain roads with granite setts, as desired by the British Electric Traction Company. The Corporation want the tramway track paved with Yorkshire stone.

**Lancaster.**—The tramway returns for the past year show a deficit of £3,180, against £2,833 for the previous year. The revenue totalled £4,908 against £4,687, and the expenditure was £8,088 against £7,520, of which the cost of energy amounted to £1,855 against £1,663 last year.

**York.**—An informal discussion took place at Tuesday's meeting of the Corporation upon the question of motor 'buses *versus* electric trams. Some disposition to favour the former has been manifested, but on this occasion there was a tendency to veer round in favour of the electric tram.

**Perth.**—Some misunderstanding appears to have arisen in regard to the height of the cars. According to the specifications these should have been 6ft. 3in., but apparently those ordered reach only 6ft. 1in. Mr. Dawson, the engineer, has been invited to attend Perth to examine the portion of the work so far completed.

**North-Eastern Railway Co.**—The new railway which has been constructed by the North-Eastern Railway Company between Newcastle-on-Tyne and Ponteland, seven miles in length, and which opens out a considerable agricultural district, was inaugurated last week. The passenger service is to be developed by means of auto-cars.

**Glasgow.**—The annual report of the Tramways Department shows traffic revenue £756,480, against £717,893 for the previous year—average revenue per car mile 10·12d., against 10·58d.; passengers 195,767,519, against 188,962,610; and mileage 17,943,595, against 16,291,082. The length of track was 144¾ miles (single), against 136 miles.

**Swansea.**—At a meeting of the Tramways Committee it was resolved that the leases between the company and the Corporation in regard to the new tramway be finally approved, the company agreeing to allow £1,000 to form part of the capital expenditure on the lines in respect to the mains from the Strand generating station to Villiers-street.

**Private Bills.**—In the House of Commons the Shropshire, Worcestershire, and Staffordshire Electric Power Bill and the Metropolitan Railway Bill have been ordered for third reading. The following Bills were read a second time: Gosport and Fareham Tramways, Hastings Tramways, Metropolitan and Great Central Railway Companies, and South Lancashire Tramways.

**Municipal Motor 'Buses.**—It was reported at the meeting of the Eastbourne Town Council on Tuesday night that the motor 'bus accounts for the past year showed a loss, allowing for depreciation, of about £1,000. As a remedy it was decided to strike off the non-paying routes and decrease the winter service. The loss was mainly attributed to the single-decked 'buses.

**Wednesbury.**—The work of reconstructing the tramway between Wednesbury and Darlaston, which has been closed for about 18 months, has been commenced. A new service of cars will, it is anticipated, be inaugurated in about three months, and it is stated that other portions of the tramways of the South Staffordshire (Lessee) Company in the same district will subsequently be reconstructed.

**Montreal.**—It is reported that arrangements are being made for the amalgamation of the companies operating the Montreal street railways and light supply. Both companies at present are making electricity for running and lighting purposes, and the projected amalgamation is for the purpose of economy in plant. No obstacle thus far has been presented to the merger, and it is believed that it will take place shortly.

Digitized by Google

**Liverpool.**—At the fortnightly meeting of the Tramways Committee last week it was decided to experiment with 1½d. fares on the Smithdown-road and Wavertree routes. The returns showed a decrease for the preceding fortnight as compared with the corresponding period of 1904 of £512. 7s. 5d., the figures being last year £21,728. 5s.; this year £21,215. 17s. 7d. There had also been decreases of 74,784 in passengers, 8,851 in mileage, and 82 in the number of cars running.

**Bradford-road Tramways.**—The latest news with regard to the electrical equipment of the Bradford-road tramways is that the British Electric Traction Company has fixed an appointment for the formal transfer of the Bradford-road tramways to the local authorities of Batley, Dewsbury, Soothill Upper, Birstall, and Gomersal, and for the signing of the leases under which the company will take over the line. When these formalities have been completed, the Batley Corporation will be in a position to seal the contract with Messrs. Dick, Kerr, and Co. for the re-equipment of the Batley portion of the track.

**Birmingham.**—At Tuesday's meeting of the City Council, the Lord Mayor (Alderman Beale) referred to the excellent progress which was being made with the development of the city's tramways. Satisfactory arrangements had been made with the City of Birmingham Tramway Company in reference to the running of the cars at the city end of the Bristol-road route. The accounts for the past year the Lord Mayor characterised as eminently satisfactory, and he gave it as his opinion that when the Corporation came into possession of the whole of the receipts of the tramway system other than the 1911 route, it would be able to start with no debt upon it.

**Seaham Harbour.**—In reference to our note last week, we hear that a syndicate, understood to be the same as that which is providing the populous Houghton-le-Spring district of Durham county with electric traction, has given notice to the local bodies concerned of its intention to apply for a provisional order to construct further lines in the East Durham district in order to embrace Seaham Harbour, New Seaham, and Burton Colliery, a very populous neighbourhood. The new routes comprise about eight miles of track, beginning at Ryhope, to which place lines are already laid, and running thence to Seaham Harbour, and on to New Seaham, Murton, and South Hetton, so as to join the system already authorised in connection with the Houghton-le-Spring scheme.

**Kimberley-Alexandersfontein.**—The opening of the newly constructed overhead electric tramway from Kimberley to De Beers marks another era in the diamond fields of Griqualand West. The line extends from Victoria-crescent, in the centre of the town, to the Alexandersfontein Hotel, 6¾ miles. The hotel was rebuilt some time since, and fitted with all the latest requirements, also by De Beers. Thanks to the tramway, the local public will be able to make much more general use of Alexandersfontein as a pleasure resort than hitherto. The current is generated by De Beers central power station at Blankenbergs Vlei. There are four cars of the latest design, and every provision is made for the comfort of passengers. For the present the trains will run every hour.—*South African World.*

**Proposed Electric Railway.**—A meeting was held at the Midland Hotel, Manchester, on Tuesday, when the scheme for an electric railway between South Manchester and some of the Cheshire suburbs (described in our last week's issue) was explained. It is estimated that the necessary capital would approximate to between £400,000 and half a million. A good deal is likely to depend upon whether the County Council insist upon bridges or allow level crossings. In the former case the expense might be prohibitory An informal resolution was carried expressing the opinion that it was desirable to construct the line. The scheme was outlined by Mr. J. M. Newton, one of the engineers, who has prepared the plans, and who was a promoter of the Manchester Southern Tramways, which the Corporation acquired.

**Paris Metropolitan Electric Railway.**—The balance-sheet of the Compagnie du Chemin de fer Métropolitain de Paris shows the following general results for 1904. The length of line worked from Jan. 1 to Oct. 18 was 24·818 km. (15·37 miles), and from Oct. 19 to Dec. 31 30·851 km. (19·1 miles), making an average of 26 037 km., or 16·1 miles, for the year. The opening of line No. 3 in its total length on Jan. 25, 1905, brought the total line up to 31·818 km. (19·4 miles). The total proceeds were £824,490. The expenses were £351,185, giving a ratio of 42·49 per cent. against 42·9 in 1903, 41·52 in 1902, and 47·17 in 1901. The gross profits were about £473,000. After paying the royalties due to the municipality, which amounted to about £265,000, there remains a net profit of about £208,000. The average profit per kilometre was therefore £8,004, or about £5,000 per mile.

**Rochdale.**—After some delay the Local Government Board have replied to the Corporation's application for sanction to a loan to extend the electricity works, part of the extension being for the purpose of supplying energy to the trams. To the surprise of the Tramways Committee, the Board now suggest that the Corporation should make arrangements for a supply with the Lancashire Electric Power Company, who, it is understood, are willing to provide same on some such terms as the following: for any quantity up to 100,000 units per annum for tramway purposes, 1·3d.; for any quantity in excess of 100,000 and not exceeding 200,000 units, 1·2d.; for any quantity in excess of 200,000 and not exceeding 300,000 units, 1·1d.; for any quantity in excess of this amount, 1d. Therefore, for 200,000 units the cost would be 1·25d., as against 1·43d. The Corporation, like their neighbours at Heywood, have decided not to entertain the offer.

**Heywood.**—At a special meeting of the Tramways Committee last week, the tenders for the tramway track, overhead equipment, and extensions to the electricity works necessitated by the decision to adopt electric traction were considered. Some details of these appear in our "Results of Tenders" column. The work will involve an expenditure of some £29,400, which is more than £2,000 less than the engineer's estimate. A general resolution was adopted to extend the electricity works as required, and to proceed with the electrification of the system. The heads of the agreement for working the trams in Heywood, which had been agreed upon by the sub-committees of the Bury, Heywood, and Rochdale Tramways Committees, were submitted and approved subject to one or two minor alterations. The Hopwood section is not included in the scheme for which tenders have been accepted. It is expected that the work will be completed in about five months. The offer of the Lancashire Electric Power Company to supply energy has been refused.

**Belfast.**—At the meeting of the Tramways Committee on Monday, the town clerk read Mr. Balfour Browne's opinion *re* overhead telephone wires, which was to the effect that the Corporation had full power to order the removal of any such wires which would interfere with the wires for the tramways, and he was requested to inform the company of this decision, which the Corporation would carry out. Mr. Nance explained that during the time that the Belfast Street Tramways Company had a lease from the Corporation the watering of the track was attended to by themselves, and he now asked that the Works Committee should make such arrangements as would ensure its being watered as well as the other portions of the streets. He pointed out that a watered track was much more comfortable for passengers when there was dust flying about than one which had not been so treated. It was decided that this should be done. On the consideration of the Tramway Committee's minutes, an amendment that the question of the fair wages clause should be referred back was negatived by the casting vote of the chairman, it being held that the sub-contractors, Messrs. Combe, Barbour, and Co., have substantially complied with the clause.

**Aston.**—The suggestion made by the Town Council on behalf of the City of Birmingham Tramway Company, that the Corporation of Birmingham should replace it as workers of the tramways in Aston, apparently remains at the suggestion stage. A proposal to this effect was made in the first week in April, when it was announced at a meeting of the Town Council that the town clerk had replied to the communication from the company stating that in the event of the Birmingham authorities being willing to take the place of tramway companies under the agreement of June, 1903, the Public Works Committee would be prepared to recommend the Council to enter into such agreement as might be necessary to give effect to the suggestion that the Birmingham Corporation should take the place of the company in the matter of working the trams in the Manor. Apparently each of the three parties is waiting for one of the others to make a move. The tram company is under a covenant to pay Aston a minimum amount of £1,200 a year. Birmingham would be willing to work the trams in Aston as in other surrounding districts, and pay to those districts the net profits earned in those respective areas. The company says it is prepared to stand on one side altogether and let Birmingham go and work the trams in the Manor, as it is in a better position to do so than the company under the existing conditions. Aston, however, is not inclined to release the company from its bond except for something in the nature of a *quid pro quo*.

**London County Council.**—The scheme for reconstructing several tramways, extending over 17 miles, to which we referred in our last week's issue, was again before the Council on Tuesday, when, after some discussion, the proposal was adopted. The accounts for the year ending March 31 show that the total receipts were £682,095 (to which the electric trams contributed £548,295, and the gross surplus £182,269, this being entirely derived from the electric lines, as the horse trams showed a slight deficiency. The total receipts are £145,856 more than in the previous year. The passengers numbered 164,818,560, being 31,679,475 more than the previous year, and the car miles 14,081,397, an increase of 2,544,853. The operating expenses work out at 7·49d. per car mile. The length of the system operated was about 47 miles, exclusive of the London, Deptford, and Greenwich Company's line, acquired in July. The top covers are considered to have materially contributed to the revenue. The net capital expenditure amounted in all to £2,623,692. In regard to the northern system, leased to the North Metropolitan Tramways Company, but about to be taken over and reconstructed by the Council, the receipts amounted to £59,846. The construction of the tramway subway from Kingsway to the Strand is approaching completion, and the Highways Committee recommended that £5,000 be voted for concreting up certain portions of the walls. The South-East London Tramway Company's undertaking has been transferred to the Council. The City Corporation last week discussed the Embankment scheme in the light of the decision of the House of Commons Committee, and eventually the matter was referred to the Streets and Bridges Committee. The proposal to run the trams along Stamford-street instead of the Embankment is being revived.

**Aberdeen.**—Judgment was delivered last week in the action brought against the Corporation by the Great North of Scotland Railway Company. The plaintiffs are the owners of the Palace Buildings. The site was acquired from the Town Council of Aberdeen under two dispositions dated 1851 and 1864. The plaintiffs maintained that they were entitled to a foot pavement of their property in Union-street of the width of 10ft. beyond the 8ft. 6in. of foot pavement which is their own property, and in Bridge-street of the width of 8ft., and they stated that the width of pavement to which they had a right had been seriously curtailed by a junction which the defendants had made between their tramways in Union-street and Bridge-street. They sought a declaration in those terms, and additional or alternative remedies. The judge found (1) that the plaintiffs having objected to the construction by the defendants of the junction between the tramways in Bridge-street and in Union-street, the defendants were not entitled in view of the provisions of Section 10 (2) of the Tramways Order, 1903, to construct the junctions so that any rail should be nearer than 9ft. 6in. to the outside of the footpath *ex adverso* of the plaintiffs' property in those streets, as they existed when notice was given by the defendants to the plaintiffs of their intention to construct

Digitized by Google

the junction; and (3) that the defendants were not entitled, for the purpose of enabling them to construct the junction on the lines proposed, notwithstanding the objection taken by the plaintiffs, to diminish the width of the footpath to such an extent as was required to leave a space of 9ft. 6in. between the outside of the footpath, as so diminished in width, and the nearest rail of the junction. He therefore granted an injunction prohibiting the defendants from using the junction, and made an order for the restoration of the footpaths of the plaintiffs' property to the condition which they were in before. The costs to be paid by defendants. The receipts for the year ended the 27th ult. show a total of £68 084 as compared with £62,794 for the previous year, an increase of £5,289. The expenditure on power and wages amounted to £30,056 as compared with £26,530 for the previous year.

**Bradford.**—The results of the year's working of the trams were outlined at last week's meeting of the Corporation. The traffic income was £223.541, but to this amount must be added sundry other receipts. The parcels department brought in £1,840, mails £138, advertising on cars £3,222, the Bowling Shale Hill £1,020, and bank interest £284, making, with one or two minor sums, a total income of £230,369. The previous year the amount was £197,437, so that there is an increase of £32,932. Against this must be put an increase in the expenses of £30,401. The total expenditure, including all charges on capital, amounted to £214,439, against £184,037 in the previous year. The pay of the general officers and staff accounts for £2,983, motormen and conductors £45,388, and other employés £3,471, making a total of £51,842, the previous year's total being £44,751. Amongst other working expenses, £19,134 is credited to maintenance of cars, £7,417 to cleaning and oiling cars, £6,986 to the maintenance of permanent way, £3,515 to the electrical equipment of lines, and £1,162 to fuel, light, and water for depôts. During the year compensation was paid to the extent of £4,600, and the department's contribution to rates and taxes totalled £8,580. The charges for power amounted to £39,196. The previous year's cost was £33,675. Turning to the various capital charges, we find that from the £70,228 gross profit a total of £54,582 has been deducted, leaving £15,646, to which £284 bank interest is added, making a net profit of £15,930. The chief items deducted are £24,491 for sinking fund and £23,661 for interest on capital, the two together totalling to £48,152, as compared with £46,106 for the previous year. Repayment of mortgage loans accounts for £949, rent of leased lines for £4,000, and income tax for £1,000. The surplus of £15,930 goes to the reserve fund. Up to March 31, 1904, the amount standing to the credit of the depreciation and renewals fund was £28,056, but with the addition of the above sum the total will reach £43,986. The question of ½d. fares was again raised in the debate, but there is no indication of a reduction being effected at present. Doubtless the exhibition and the fine weather contributed to the satisfactory results obtained last year, but, judging by general appearances, there should be little, if any, falling off this year if the weather be favourable. For May the receipts were some £2,000 less than for the corresponding period of last year, when, it must be remembered, there was the substantial benefit of the Whitsuntide holidays. With this advantage in hand the difference may be cleared off during the present month.

## LIGHTING AND GENERAL.

**Aberdeen.**—The output at the electricity works during April amounted to 350,726 Board of Trade units.

**Harrogate.**—All-round reductions are being made in the price of current for private lighting and power purposes.

**Barrow.**—The Corporation electrical works made a profit last year equal to a 1d. rate, or 7½ per cent. interest on the capital.

**Dudley.**—The Town Council have agreed to the re-engagement for a further six months of Mr. R. Wilson, their electrical expert.

**Hanwell.**—The amended agreement with the Uxbridge and District Electric Light Company has been approved by the District Council.

**Brynmawr.**—An electric lighting installation, which could be laid down for the whole district at a total cost of about £8,000, is under consideration.

**Ripon.**—Circulars are being issued with a view of finding out whether the leading citizens are in favour of the introduction of electric light.

**Bridgetown (Somerset).**—It is said that this hamlet is the smallest centre in England to have an electric installation. It is thought that all the cottagers will take the light.

**London Electric Power Supply Bill.**—The Administrative County of London and District Electric Power Bill was read a third time, and passed, in the House of Lords on Tuesday.

**Calcutta Electric Supply Co.**—The number of units delivered to consumers during the four weeks ending April 28 is reported as 301,369, compared with 289,653 in the corresponding four weeks of the preceding year.

**Bradford.**—The Town Council intend to apply for sanction to borrow £60,000 for the purpose of carrying out certain extensions to mains in order to enable the department to meet the constantly increasing demand for current.

**New Issues.**—The Sir Hiram Maxim Electrical Company, Limited, are issuing 15 000 6 per cent. preference shares, and the Newcastle and District Electric Lighting Company £150,000 of 4½ per cent. mortgage debenture stock.

**Brighton.**—On Tuesday the mayor received the delegates of the Postal and Telegraph Benevolent Society at the Royal Pavilion. They were entertained by the Duke of Norfolk, formerly postmaster-general, at Arundel on Wednesday.

**Middlesbrough.**—Mr. Taylor's last report shows that the estimated profit for last month, exclusive of interest and redemption, was £461, and the number of lights at present connected was 77,000, whilst there were new applications for 420.

**Metropolitan Electric Tramways Bill.**—This Bill, conferring powers on the company compulsorily to acquire land in the county of Middlesex and to widen and alter roads for the purpose of the undertaking, has been reported for third reading.

**London County Council.**—On Tuesday it was agreed to lend the Poplar Borough Council £3,660 for electric light installation and meters. A large number of notices under Electric Lighting Acts and orders of intention to lay mains were agreed to.

**Cheltenham.**—The last monthly report of the electrical engineer shows that there were 817 customers, with the equivalent of about 54 640 8-c.p. lamps, connected to the private supply mains, the corresponding figures for 1904 being 763 and 48,890 respectively.

**Ashton.**—The Guardians at their last meeting discussed a recommendation to apply for power to borrow £5 000 for electrical purposes at the new hospitals and the wiring of the old workhouse. The voting was against the proposal, but notice to rescind has been given.

**Agency.**—Messrs. R. J. Nicholson and Co., 26, Cannon-street, Manchester, have been appointed sole agents in Manchester and district for Messrs. Joseph Richmond and Co.'s lifts and cranes. Messrs. Nicholson and Co. will furnish full prices and particulars on receipt of enquiries.

**Rand Central Electric Works.**—The result for May is reported as follows: "Kilowatt-hours generated 972,000, yielding a gross revenue of £9,000." For the corresponding period of last year the result was kilowatt-hours generated 968,000, yielding a gross revenue of £8,500.

**Wrexham.**—The borough electrical engineer's last report shows that 14,466 units were used for tramways in April, 1905, and 29 052 units for lighting, etc. The total consumption amounted to 43 518 units, compared with 34,138 in April, 1904. Two new consumers were connected. The total number of consumers is at present 179.

**Burton-upon-Trent.**—Sanction has been received for loans amounting to £5,611 to defray excess expenditure on works for which loans have previously sanctioned, £4,000 for the extension of mains, etc., and £500 for the provision of a 100-kw. continuous-current tramway generator, regarding which an enquiry was recently held by the Board of Trade inspector.

**Electricity Supply Company for Spain.**—The second drawing for repayment of 77 6 per cent. first mortgage debentures and 43 7 per cent. "B" mortgage debentures has just been made. These bonds will be paid off at £100, with interest to date added, at the office of the company, College-hill-chambers, College-hill, London, E.C., on June 30, 1905, from which date interest will cease.

**Catalogue.**—We have received from Messrs. Matthews and Yates, Limited, Cyclone Works, Swinton, Manchester (London, 84, Gray's-inn-road, W.C.), a reduced price-list of their well-known cyclone air-propellers for ventilating, cooling, and drying purposes. We are informed that the reduction is due to up-to-date plant installed owing to the increasing demand for their appliances.

**Portsmouth.**—On Tuesday Portsmouth was practically cut off from telegraphic communication with the outside world for some hours, owing to the heavy rainfall of Monday, which flooded various parts of the town, including the underground channel in which the telegraph wires are carried from the railway to the post office. The telephone trunk lines were used for telegraphic purposes.

**Lincoln.**—At Tuesday's meeting of the City Council Mr. C. Pratt said the electricity works reflected credit on the management. The profits had steadily increased from £3,493 last year to £3,928 in this, an increase of £403. The deficiency, which stood at £907 last year, was practically wiped out. The contractors were pushing forward as quickly as possible, and they hoped to start the tramway soon after Whitsuntide.

**Ossett.**—The Town Council last week discussed a proposal that the standing orders be suspended to enable the Council to reconsider their decision in regard to the electricity undertaking, and that the resolution passed at the meeting of the General Purposes Committee on April 4, relating to the proposed electric lighting station, and confirmed at the Council meeting on April 10, be rescinded. The attempt to reopen the question failed by one vote.

**Bath.**—An enquiry has been held into the Corporation's application for sanction to a loan of £19,000 for electric lighting purposes. The application of the National Telephone Company for permission to extend the system of underground mains in the city has been referred to the Sub-Surveying Committee jointly with the Electric Lighting Works Sub-Committee, the town clerk and surveyor being asked meanwhile to confer and draw up a draft agreement with the company.

**Eastbourne.**—A recent report shows that in the 5¼ years of its existence the electric works have produced a profit of £14,000, of which £4,000 has been paid to the depreciation fund and £750 to the relief of the rates. The accumulated surplus was £9 412 and the profits for the year £2 725, of which £2,000 is to be devoted to depreciation fund and £725 to the relief of the rates. The committee have decided to reduce the charge from 6d. to 5½d. per unit. That will mean a reduction of income of £1,450 per annum.

**Stock Exchange.**—The Stock Exchange Committee have ordered the British Westinghouse Electric Manufacturing Company's further issue of £400,000 4 per cent. mortgage debenture stock to be quoted in the official list. Applications have been made to the committee to allow the following securities to be quoted in the official list: the Adelaide Electric Supply Company's 10,000 6 per cent. cumulative preference shares of £5 each, £3 paid; and the Eastern Extension, Australasia, and China Telegraph Company's further issue of £150,000 4 per cent. mortgage debenture stock (perpetual).

**Whitby.**—The report of the Lighting Sub-Committee on the working of the electricity department for the year ending March 31, 1905, shows a profit of £307, against which had to be paid £1,702 for principal and interest, leaving £1 395 to be met from the rates. This sum a year ago was £1 673. The number of lamps connected in equivalents of 8 c.p. was 9,124, as against 6,175 last year—an increase of 2 949. Of the 9,124 lamps, 7,768 were private and 1,356 public. During the year the price to private consumers was reduced from 6d. to 4½d. (net) per unit. The number of units sold had increased in the 12 months from 85,961 to 125,779.

**Stockton-on-Tees.**—Gas continues to maintain itself as an illuminant against electricity at Stockton-on-Tees, and the Gas Committee of the Corporation has just completed the installation of new mechanical charging and discharging apparatus, which, with a range of new workshops, has cost the town £9 000. All the new machinery is actuated by electricity, and supersedes hand charging etc. The capacity of the Stockton gasworks is now equal to 500 million cubic feet per annum, and the Corporation expects to make still larger profits than the £7,000 per year, which on last year's trading was available for reducing the rates, although consumers are charged only 2s. per 1,000 feet.

**Bo'ness.**—A special meeting of the Town Council was held last week for the purpose of meeting Mr. W. B. Cownie, general manager and secretary of the electric company, and Mr. Monkhouse, consulting engineer, to discuss various matters connected with the electric lighting scheme. The burgh surveyor submitted a report on the proposed lighting scheme for the burgh. Mr. Monkhouse said he approved of the scheme as proposed by Mr. Lawrie. After discussion it was agreed that before the scheme be adopted and extensions laid, the Council extend their borrowing powers, or, alternatively, that only as much of the work as could be done with the money in hand be carried out, so as to save further borrowing for the scheme.

**Lancaster.**—It has been arranged that in consideration of a credit of £500 the Electricity Committee waive all claims for penalties and damages against the Westinghouse Company in connection with their contract for the supply of generating station equipment and switchboard, and to accept an equivalent amount of electrical apparatus manufactured by the company in lieu of the £500 in cash. Further, that the final balances due to the Westinghouse Company under their contracts with the Corporation be paid, excluding a sum of £500 to be retained by the Corporation pending the supply of the electrical apparatus above referred to. In connection with the new town hall scheme, certain cables are to be removed, etc., at a cost of £517.

**Darlington.**—The electricity department of the Corporation has been successful since the commencement, and the statement of accounts for the year ending March 31 last shows a profit, after payment of interest and depreciation, of £1,449, equal to about one-half the loss on the year's working of the municipal light railways. The consumption of electricity in the borough is increasing satisfactorily, and it is being adopted for motive power purposes. From the end of the present month the Corporation of Darlington has decided that the charge for electricity shall be 4d. per unit up to 20,000 units, and 3½d. per unit for all above 20,000 units. For power purposes the charge will be reduced to 1½d. for the first 500 units supplied per quarter, and 1½d. for all over that amount supplied during the same period.

**London Gazette.**—A receiving order has been made out on debtor's petition in the estate of F. Shaw, electrical contractor, 258, Hessle-road, Kingston-upon-Hull. The partnership between Arthur Ronald Holmes and Charles Walter Scott Nicholson, carrying on business as accumulator manufacturers and electrical engineers at 231, Liverpool-road, Islington, N., under the style of G. R. Holmes and Co., has been dissolved by mutual consent. The partnership between Robert Gray Linscott and Guy Clement Hurrell, carrying on business as electrical engineers at 148, Aston-street, Birmingham, under the style of the Cable Accessories Company, has been dissolved by mutual consent. A receiving order has been made out on creditors' petition in the estate of Alex. Gavan Inrig, electrical engineer, 16, Bruce-grove, Tottenham, Middlesex. A winding-up order has been made out in the estate of the Garcin Renault Electric Cars and Accumulators, Limited, Denman-street, London.

**Hammersmith.**—At the last meeting of the Guardians the Building Committee reported that they had had an interview with Mr. J. Enright (of Messrs. J. and J. S. Enright, electrical engineers), who had informed their committee that the firms whose tenders for the transforming apparatus and electric wiring were provisionally accepted at the last meeting desired to withdraw such tenders, and therefore under the circumstances the committee recommended the acceptance of the tender received from Messrs W. J. Fryer and Co., of the Bravington Works, Bravington-road, Paddington, W., in the following sums—namely: Section 1, electric wiring, £4,580; Section 2, transforming apparatus, £1,061—total, £5,641. The committee further recommended that Messrs. Watson, Sons, and Room, solicitors, be instructed to prepare the contract to be entered into with Messrs. Fryer providing for the carrying out of the work. After discussion it was agreed that instructions be given to the engineer to report in writing in the matter in which these people had not complied with the specifications.

**Bath.**—An enquiry was held on Tuesday into the application of the Council for power to borrow £19,000 for electric light purposes. Of this, £9,000 is for excesses of expenditure over estimates in respect of works carried out, which were discussed in the Council some months ago, the principal items being £1,368 excess on the building of engine and boiler house and river-wall; £2,166 on boiler, chimney, and steel flue; £830 for main switchboard extension; £1,979 on sub-station switchgear; £1,815 on high and low-tension feeders and roadwork, etc.; £802 on extensions to low-tension distributors; and £700 on engineer's fees and contingencies; £7,000 is for the provision of more plant and the execution of additional works at the station, including £150 for boiler-house plant; £540 for water-softening plant; £230 for transfer of distributors; £4,195 for a storage battery scheme; £2,945 for generating plant; £3,000 for extensions to mains and new services; £480 for increase of size in motor-alternator; £175 for new connection at the Gravel-walk sub-station; £325 for Manvers-street power main; and £3 000 for extension of mains.

**Warrington.**—The report of Mr. F. V. Mathias, borough electrical and tramways engineer, on the working of the electric supply undertaking during the year ending March 31 shows that a reduction in charges for current to the extent of £625 has been made to the tramways as compared with last year. There is also a decrease equivalent to 20·93 per cent. in public lighting, and the contribution to interest and sinking fund charges has been increased by £540 in excess of last year. The gross revenue amounts to £12,560, working expenses take £6 075 leaving a balance of £6,505. Out of this has been paid: interest on capital, £2,461; sinking fund, £3,276; rates income tax, etc., £224; leaving net profit on year's working of £1,543, as against £128 for the previous year. During the year the equivalent of 8,345 8 c.p. lamps has been added to the mains. The total revenue from private lighting and power is £12,070 representing 1,482,456 units—288 261 units for lighting and 1,194,195 for power—being an increase of £1,081 and 283,455 units over last year, the average yield being 1·954d. per unit, which is a low figure, and compares very favourably with other towns. The cost of production shows a material reduction per unit as compared with last year.

**Capo Telephones.**—The introduction of the telephone system into the Cape Colony has, according to the *British South African Export Gazette*, proved, as elsewhere, no inadvisable step from the point of view of a profit-earning concern, and hence Sir Lewis Michell was able to affirm its flourishing condition on a recent occasion in the Cape Parliament. In a year of reputed depression it has shown a net profit of £765 on its working, and thus justifies those pressing extensions and improvements which Sir Somerset French, the Cape Postmaster-General, deems necessary. His programme contemplates a total expenditure of £187,876 on new lines and exchanges, of which £53,452 stands for unexpended capital already sanctioned, and indents for new machinery and material have, as a matter of fact, long since been framed. In view of the certain returns which this outlay must give, the Cape Parliament should have no hesitation in granting the funds, and, at the worst, the postponement of a grant cannot be deferred immediately. It is worthy of note that the dearth of workmen skilled in laying pipes and cables in the Cape Colony is such that extension works of the department have been greatly retarded. Moreover, the invocation of the assistance of the Agent-General in London had proved unavailing to find a remedy.

**Chatham.**—Early on Saturday last the electric lighting works of the Kent Electric Power Company at Chatham were destroyed by fire. From the information received we gather that the whole of the dynamos and engines have been completely destroyed, and that only one or two of the boilers are likely to be of further service. The inconvenience caused by the fire is considerable, owing to a large number of business hours being dependent upon electric lighting. We understand, however, that arrangements have been made to continue the supply from the Corporation of Gillingham. It seems that the origin of the fire was not electrical, but it is thought to have been due to the carelessness of a workman who was making some structural alterations to the building. Immediate steps were taken for the purpose of restoring the supply, and after various methods had been discussed the plan of taking a supply of current from the Gillingham Corporation, which was offered to the company, seemed to be the most feasible. The chief difficulty apparently in the way of doing this was the provision and laying of a high-tension main over 1,000 yards long across the ground known as the "Chatham lines." To do this it was necessary to obtain the consent of the War Office, and, of course, also at the same time to complete a bargain with the Gillingham Corporation as to the terms upon which the current would be provided. We are glad to be able to say that both these negotiations have been carried through successfully, and that in all probability the current will be again available for the public immediately after the holidays, and we think that the officials of the War Office, the Gillingham Corporation, and the Kent Power Company are to be congratulated upon the rapidity with which these negotiations have been completed. In regard to the permanent supply, we are asked to state that the Kent Electric Power Company anticipate that their new power station at Frindsbury will be in a position to supply energy before the end of the present year.

**Blackburn.**—Mr. P. P. Wheelwright, borough electrical engineer, in his report (shortly noted last week) says that the effect of the reduction in the charges was clearly demonstrated by the fact that, although nearly a quarter of a million more units had been sold during the year the net revenue was £300 less than that of the previous year. The expenditure had been reduced £200 notwithstanding this increased output, whilst the capital charges exceeded those of last year by £1,270. The number of units sold during the year for all purposes had increased from 2,895 181 to 3,129,215, the works cost of which had been reduced to ·65d. per unit sold, a figure comparing most favourably with the results obtained by other towns having similar undertakings. The total number of consumers taking supply from the mains was 1,110 being an increase on last year of 120, aggregating in 8 c.p. lamps 17,184, and the total number up to date connected to the mains to 106 358, exclusive of tramways demand. During the year 80 motors, totalling 380 b.h.p., had been connected to the supply mains—of these 57 motors, or 275 b.h.p., having been supplied and fixed by the department, the remainder being the property of the consumers. At the present time there were 140 motors on loan, and maintained by the works staff, of an aggregate horse-power of about 500. The total number of motors in use up to March 25 was 260, of a total capacity of 1,150 b.h.p., which provides a day load for the station plant and tends to economical production of current. Mr.

Digitized by Google

Wheelwright considers that during the present year the motor business will be rapidly increased, owing to the better trade conditions, coupled with the very low charges which came into operation last July.

**Islington.**—The Lighting Committee of the Borough Council presented the following report at the meeting on Friday: "Referring to the report which was presented to, and which was adopted by, the Council on April 14 last, recommending, *inter alia*, the purchase of six mechanical stokers, satisfactory tests have been made at the electric lighting station with the mechanical stoker of the chain-grate type manufactured by Messrs. Babcock and Wilcox, and we are of opinion that in view of the economy that will be effected by their use, it is desirable that at least three sets of these stokers should be put into operation as soon as possible. We therefore recommend that three sets of chain-grate mechanical stokers, costing £900, be at once ordered from Messrs. Babcock and Wilcox, subject to their agreeing that the Council shall not be liable for any payment therefor until the sanction to the loan has been received from the London County Council." In the course of the discussion Alderman Mills said that the use of these stokers would mean a reduction of the coal bill by one-half. The report was agreed to. At the same meeting the Lighting Committee stated as follows: "We have received a report from the electrical engineer to the effect that Messrs W. R. Rershaw and Co., with whom the Council on Aug. 5, 1904, upon our recommendation, entered into a contract for the hire of 40 12-ton coal wagons, at £7. 12s. 6d. per wagon per annum, for a period of five years, have gone into liquidation, and that the agent for the trustees of the debenture holders has suggested that the contract should be transferred to the British Wagon Company, of Rotherham. We understand that the latter firm are willing to undertake the contract, but that they object to the Council retaining the option to determine the agreement at the end of one year upon payment of an additional £1. 12s. 6d. per wagon. We recommend: (*a*) that the Council do approve of the transfer from Messrs. W. R. Rershaw and Co. to the British Wagon Company of the contract for the hire of coal wagons as above mentioned; (*b*) that the Council's option to determine the agreement at the end of one year be eliminated from the contract." The recommendations were agreed to.

**Finchley.**—An enquiry is to be held into the proposed loan of £23,500 for electricity works. The electrical engineer has been authorised to proceed with such preliminary works as is necessary for supporting the new feed tank, removal of pumps to original pump-house, and the preparation of foundations for No. 5 boiler, together with the requisite pipe alterations, all of which will be carried out by his own staff as before. The electrical engineer's annual report gives the following particulars: "On April 1, 1904, the plant included in the original loan (£35,600) was practically all installed, with the exception of a few minor details, and with the exception of a certain balance of cable included in the contract which had not been laid. At that time there was a considerable falling off in the applications for current, and the progress of the undertaking appeared somewhat doubtful. In view of this I instituted a system of canvassing, whereby all builders and others were called upon at short intervals, and every inducement within my authority was offered them to wire their houses. I am pleased to say that the effect of this was immediately felt, and applications have been coming in during the whole of the 12 months at a nearly uniform rate of 235 8-c.p. lamps per week, with the result that at the end of May it was apparent further plant would be required for the following winter's load and I presented you my estimate for first extensions of £15,000. This amount was subsequently increased by the Council to £17,000. The Local Government Board disallowed £400 for spare armature, leaving an amount of £16,600. These extensions were put in hand forthwith, and some considerable trouble was caused owing to the short date for delivery; but plant which was absolutely essential was erected in October, and although many of the details are not yet finally completed, the whole of the machinery was erected and used during the last winter. Applications still continued to come in at a uniform rate, and in February last it became evident that further extensions would be required to meet next winter's load. I therefore reported to you and submitted a further estimate for extensions No. 2 of £23,500. At the end of the year (March, 1905) I made a thorough inspection of various plant, and have pleasure in reporting that all was in a satisfactory condition on that date. During the 12 months there have been no serious breakdowns. On two occasions the supply was interrupted for a few minutes—in one case owing to a fault on a consumer's premises, and in the other case owing to a cart having been driven over a soft footpath and caused derangement to a joint box on the cable. During the year several consumers discontinued receiving supply owing either to bankruptcy or to their leaving the neighbourhood; in most instances the premises have been re-let, and the consumers regained. For comparison with figures of other undertakings published from time to time, I have pleasure in placing the following statistics before you: units generated, 296,400; units sold—consumers, 152,179; sold—public lighting, 105,000; used on works and battery, 26,300; mains loss and unaccounted for, 12,921."

**Rochdale.**—The annual report of the Corporation Electricity Committee shows that during the year ended March 31 there was an additional number of consumers approximately the same as during the previous years, though the number of equivalent 8-c.p. lamps connected did not show so large an increase, the new consumers during the last year being mostly shops and private houses. We quote from the report as follows: "The increase in the maximum load has been in almost direct proportion to the number of consumers, but the units sold have very considerably increased per equivalent 8-c.p. connected, thus giving a better load factor on the generating plant. The increase in the consumers with fewer numbers of lamps or small motors is having a beneficial effect, and has a tendency to minimise the trouble caused by the consumers with a large number of lights who only rarely use the whole of them for any length of time. The year has seen an increase also in the number of units supplied to the tramways department, but the increase in the maximum load has been very considerable and has counterbalanced the gain, the load factor for the year showing no material increase. This, of course, is due to the new sections having only run for a portion of the year, and should be somewhat rectified during 1905-6, but as Littleborough will not be fully working the whole year much the same will occur then, though it is hoped in a lesser degree. The suggestion having often been made that this committee was short of power for the tramways, it is interesting to note that the estimate of 27 cars, which it was stated the existing plant could supply, has been fulfilled. The prices charged for the supply of electricity have remained as before, but the increased number of units sold for tramway purposes have reduced the average price obtained for all units sold from 2·096d. last year to 1·98d. for 1904-5. The interest and sinking fund charges have increased this year, and there will be a considerable addition to them for the year 1905-6, owing to the extensions of plant carried out during the financial year, for which the first payments have not yet become due. As mentioned in the report for 1903-4, the Council, at its meeting on May 5, 1904, passed a resolution to extend the present plant at Dane-street. Estimates were then obtained, and application was made to the Local Government Board on June 3, 1904, for powers to borrow £42,405 for electricity supply purposes. On Jan. 18 of this year an enquiry was held by Mr. H. Ross-Hooper, one of the Local Government Board inspectors, and the Corporation awaits the sanction of the application. As, however, it was essential to make use of the light days for getting on with the works, the following portions have been commenced and are either completed or nearing completion. The accumulators have been moved and re-erected, the room thus set at liberty being converted into a switch-room and the lighting and traction switchboards removed thereto. A three-phase switchboard is also in course of erection. The main engine-room building has been practically doubled in length, and already three out of five steam sets it is capable of holding have been installed, as also has one motor-alternator. The steam, exhaust, and condensing-water pipes are almost completed, and the condensers for the new sets have been erected. Considerable alterations and extensions of the cable work in the generating station have been necessitated, and the major portion is complete."

**Sheffield.**—The Corporation Electric Light Committee on Tuesday approved the statement of accounts of the electric supply department for the year ended March 25 presented by Mr. S. E. Fedden, the general manager and engineer. The engineer draws attention to the report dated Oct. 22, 1901, which was presented to the Finance Consultative Committee, in which he estimated that a deficiency of £2,850 would be shown on the year's working when the gross revenue amounted to £60,000. Mr. Fedden says: "Our progress, however, has not been so rapid as I anticipated, owing chiefly to trade depression, which has retarded the growth of our business, particularly in the supply of electricity for power purposes, and also owing to the much higher average of bright weather during the past two or three years, as shown on the 'Progress Chart' which I am submitting to you. For the year ending March 25 last, with a turnover, from all sources, of £59,395. 3s. 5d., the accounts show a loss of only £650. 9s. 7d., after meeting all charges, a result considerably more than £2,000 better than was anticipated. This is due chiefly to the great reduction in the works costs consequent upon the use of our new plant at Neepsend, which, although only in regular service during five months of the last year, has enabled us to produce and sell 4,546,141 units with an expenditure of £16,270 for fuel, wages, material, management, etc., against 3,980,049 units, with an expenditure of £17,234 in 1904, a reduction of 17·30 per cent. in the cost of each unit sold. Although I am unable to look forward to making any considerable surplus in the current year, I have no hesitation in predicting that in a comparatively short time a satisfactory and continuously increasing profit will be earned, and I would respectfully suggest that in order to hasten the financial success of this department it is important that we should be entrusted with the lighting of every municipally-controlled building, and also the principal thoroughfares of the city. It will be seen from the accounts that the capital expenditure to March 25, 1904, amounts to £740,943. 3s. 8d., and that the expenditure for the year has been £63,584. 2s. 3d., a total expenditure to March 25, 1905, of £804,527. 5s. 11d. The interest and sinking fund to be provided for out of revenue for the 12 months amounts to £43,056. 1s. 2d., the total income received from all sources amounts to £59,396. 3s. 5d., and the total cost of generation, distribution, rates, taxes, and management amounts to £16,990. 11s. 10d., leaving a gross revenue of £42,405. 11s. 7d. The interest on mortgages, stock, and bank charges amounts to £26,317. 12s. 3d., and the sixth instalment set aside out of revenue for the extinction of loan indebtedness to £16,738. 8s. 11d.—total, £43,056. 1s. 2d.; from which must be deducted the gross revenue, £42,405. 11s. 7d.; leaving a deficit, after covering all charges, of £650. 9s. 7d. The accumulated surplus to March 25, 1904, was £21,002. 6s. 9d., from which must be deducted the deficit at March 25, 1905, £650. 9s. 7d., leaving a total available surplus of £20,351. 17s. 2d. A detailed revenue account is appended, also detailed capital account, sinking fund account, and balance sheet. A diagram shows that the number of 8-c.p. lamps installed, or their equivalent, has increased from 215,000 in April, 1903, to 340,000 in March, 1905, and the December maximum number alight at one time has increased from 115,000 in December, 1903, to over 130,000 in December, 1904. The total revenue of the undertaking in the successive years of Corporation management has been as follows: 1898, £19,039; 1899 (15 months), £23,242; 1900-1 (12 months), £41,390; 1902, £39,831; 1903, £47,201; 1904, £57,100; 1905, £59,396. The number of units sold in the corresponding years respectively has been 978,088, 1,293,900, 2,381,708, 2,487,584, 2,919,722, 3,980,049, and 4,546,141. As pointed out in Mr. Fedden's report, the working expenses for the past year

Digitized by Google

show for the first time a reduction coinciding with an actual increase of units sold—viz, from £17,234 for 3,980,049 units sold in 1904 to £16,270 for 4,546,141 units sold in 1905.

## PROVISIONAL PATENTS, 1905.

MAY 27.

**11119. Accumulative mercurial gravitation safety valves for hot-water installation boilers, and engine, boiler, steam, or other pressure indicators.** Charles Mackintosh, 36, Gower-place, Gower-street, London. (Complete specification.)

MAY 29.

**11169. Improvements in carbon-holders for arc lamps.** Siemens Bros. and Co., Limited, Queen Anne's chambers, Broadway, Westminster, London. (Siemens-Schuckertwerke, G. m. b. H., Germany.) (Complete specification.)

**11233. Improvements in or relating to dynamo-electric machines.** Frederick Edmund Berry, 46, Lincoln's-inn-fields, London.

MAY 30.

**11243. Improvements in electric arc lamps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**11260. Improvements in electric cables.** Alfred Whalley and Ernest Arthur Bayles, Ashville, Helsby, near Warrington, Chester.

**11290. Telephone exchange systems.** Francis William Dunbar, 65, Chancery-lane, London. (Complete specification.)

**11300. Improved manufacture of copper sulphide for thermo-electric couples.** Compagnie Thermo-Electrique (Système Hermite) Soc. Anon., Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, April 27, 1905, being date of application in France. (Complete specification.)

**11301. Improvements in sulphide of copper thermo-electric generators.** Compagnie Thermo-Electrique (Système Hermite) Soc. Anon., Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, May 3, 1905, being date of application in France.) (Complete specification.)

**11329. Improvements in trolley wheels for electric traction.** James Alexander Kidd, 23, Southampton-buildings, Chancery-lane, London.

**11330. Improved means applicable for use in testing lightning conductors.** Arthur Annesley Voysey, Oun House, Surrey-street, London.

**11336. Improvements in telephones.** John Edward Kingsbury, 24, Southampton-buildings, Chancery-lane, London. (The Western Electric Company, United States.) (Complete specification.)

**11337. Improvements in telephones.** John Edward Kingsbury, 24, Southampton-buildings, Chancery-lane, London. (The Western Electric Company, United States.) (Complete specification.)

**11344. Improvements in and relating to insulators for electric conductors.** Robert Norman Redmayne, 70, Chancery-lane, London.

**11353. A process for regenerating electric accumulators.** Carl Luckow, 18, Southampton-buildings, Chancery-lane, London. (Complete specification.)

MAY 31.

**11407. Improvements in electric heating apparatus.** Gustav Teuter, 23, Mittelstr., Berlin, Germany. (Complete specification.)

**11415. Improvements in apparatus for measuring electrical resistances.** Evershed and Vignoles, Limited, and Sydney Evershed, 1, Queen Victoria-street, London.

**11440. Improvements in connection with single-phase alternate-current electrical motors provided with commutators.** The Elektrizäts Akt.-Ges vormals W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, July 11, 1904, being date of application in Germany.) (Complete specification.)

**11441. A device for limiting the speed of compensated single-phase alternate-current motors.** The Elektrizäts Akt.-Ges. vormals W. Lahmeyer und Co., 47, Lincoln's-inn-fields, London. (Date applied for under Patents Act, 1901, July 30, 1904, being date of application in Germany.) (Complete specification.)

**11442. Improvements in the manufacture and production of coils of wire, more especially intended for use in electrical measuring instruments.** Hartmann und Braun Akt.-Ges., 47, Lincoln's-inn-field, London. (Date applied for under Patents Act, 1901, June 16, 1904, being date of application in Germany.) (Complete specification.)

**11454. Improvements in means for automatically regulating the load on engines or motors used for driving electric current generators.** Helios Elektricitäts-Aktiengesellschaft (in liquidation), 18, Buckingham-street, Strand, London. (Date applied for under Patents Act, 1901, June 1, 1904, being date of application in Germany.) (Complete specification.)

**11424. Improvements in apparatus for controlling electric currents.** Augustus Nelson Frisby, 10, Church-road, Watford.

**11460. Improvements in and relating to fusible electric cut-outs.** British Thomson-Houston Company, Limited, and Edmund Basil Wedmore, 83, Cannon-street, London.

**11463. Improvements in electrical connections.** William Ernest Burnand, 124, Oak Brook-road, Sheffield.

JUNE 1.

**11470. Improved electric cables.** William Bacon, 15, Water-street, Liverpool.

**11484. Improvements in electrical automatic cut-outs.** Edward Woodrowe Cowan, West Bank, Disley, Cheshire.

**11491. A self-contained electric bicycle bell.** John William Perry and John William Perry, jun., Rawreth Schools, Battles Bridge, Essex.

**11494. Improvements in and relating to sealing devices for electricity meters.** William Hamilton and Ferranti Limited, 18, Southampton-buildings, Chancery-lane, London.

**11502. Improvements in dynamo-electric machines.** Gilbert (known as Alfred) Berry, 53, Chancery-lane, London. (Date applied for under Patents Act, 1901, June 2, 1904, being date of application in France.) (Complete specification.)

**12525. Improvements in the manufacture of wire and the like by electro-deposition.** Richard David Sanders, 4, South-street, Finsbury, London.

JUNE 2.

**11534. Improvements in and relating to electrical conductors adapted to be used for commutators of dynamo-electric machines and other purposes.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**11535. Improvements in regulators for dynamo-electric machines and the like.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

**13536. Improvements in and relating to electric motor control systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**11537. Improvements in and relating to electric motor control systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**11538. Improvements in systems of overhead electric railways.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**11600. Improvements in dynamo-electric machines.** Gilbert (known as Alfred) Berry, 53, Chancery-lane, London.

**11605. Improvements relating to retransmitting and reinforcing telephone currents on lines also used for telegraphic purposes or otherwise liable to have currents of relatively low frequency passing over them.** John Edward Kingsbury, 24, Southampton-buildings, Chancery-lane, London. (The Western Electric Company, United States.) (Complete specification.)

**11606. Improvements in telephone current retransmitting and reinforcing apparatus.** John Edward Kingsbury, 24, Southampton-buildings, Chancery-lane, London. (The Western Electric Company, United States.) (Complete specification.)

**11614. Improvements in electric traction.** John Smith Raworth, Norfolk House, Norfolk-street, Strand, London.

**11626. Improvements in protective device for alternating-current systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**11627. Improvements in syatems of electric distribution by means of rectified alternating electric current and in apparatus therefor.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

JUNE 3.

**11635. Improvements in the trembler blades of contact makers for electrically-fired internal-combustion engines.** Andrew Arthur Donald, 24, Temple-row, Birmingham.

**11654. Improvements in accumulator plates.** Alexander Scharshieff, 55, Market-street, Manchester.

**11673. Portable electrical measuring instruments.** Henri Bourgeois, 65, Chancery-lane, London. (Complete specification.)

**11685. Improvements in multiplex telegraph systems.** Tullio Giara, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**11702. Improvements in dynamo-electric machines.** (The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

**11703. Improvements in and relating to dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

Digitized by Google

**11765. Improvements in and relating to electric arc lamps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published June 22.*

1904.

**12365. Telphers.** Siemens Bros. and Co., Limited. (Clift.)

**12372. Apparatus for transmitting and receiving telegraphic signals and the like.** Armstrong and Orling.

**12375. Electric clocks or time indicators and like mechanism.** Bowell.

**12623. Electric controllers.** British Thomson-Houston Company, Limited. (General Electric Company.)

**12801. Dynamo-electric machines.** Sayers.

**12861. Electric contact devices or collectors for electric traction.** British Thomson-Houston Company, Limited. (General Electric Company.)

**13360. Electrical measuring apparatus.** British Thomson-Houston Company, Limited. (General Electric Company.)

**13902. Electric insulators.** Aiken.

**14058. Solutions for the electro-deposition of metals.** Potthoff.

**14276. Single-phase electric motors.** Punga.

**15632. System of protection for parallel electric feeders.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15646. Electrical fuse distribution and like boxes.** Veritys, Limited, and Gott.

**16108. Alternating-current electric motors.** British Thomson Houston Company, Limited. (General Electric Company.)

**16426. Contact breakers for induction coils.** Butt and Cox.

**16586. Point mechanism for electric tramways and the like.** Lawrence.

**16595. Supporting devices for electric fans.** Leach and Bergtheil.

**16601. Telephone central-station systems.** Lambert.

**16663. Electric meters.** British Thomson-Houston Company, Limited. (General Electric Company.)

**16729. Contact shoes for electrically-propelled vehicles.** British Thomson-Houston Company, Limited. (General Electric Company.)

**16837. Electric conductors more especially intended for use with "earthed" pipes, or pipes for protecting electrical conductors.** Johnson. (Hartmann und Braun Akt.-Ges.)

**18020. Electrical driving mechanism for machinery in general.** Hill.

**26791. Transformers and the like for use with compounded dynamo-electric machines.** Heyland. (Date applied for under International Convention, Dec. 8, 1903.)

**28166. System of connections for the generation of electric oscillations.** Eichhorn. (Date applied for under International Convention, Dec. 20, 1903.)

**28434. Electric insulating material and the process of manufacturing the same.** Billwiller and Karrer.

1905.

**956. Vapour electric apparatus.** Wood. (Date applied for under International Convention, Jan. 18, 1904.)

**1384. Electric apparatus for felling trees or sawing wood.** Wilson. (Date applied for under International Convention, Jan. 30, 1904.)

**1518. Binding screws and terminals for electric conductors.** Maunsell, Butt, and Harry W. Cox, Limited.

**2934. Temperature compensating devices for thermo-electric temperature measuring instruments.** Bristol.

**4859. Field-magnet arrangements of alternate-current electrical machines.** Elektrizitäts Act.-Ges. vorm. W. Lahmeyer und Co. (Date applied for under International Convention, April 30, 1904.)

**5834. Windings of field magnets of dynamo-electric machines.** Siemens Bros. and Co., Limited. (Siemens-Schuckertwerke G. m. b. H.)

## NOTES.

**City and Guilds of London Institute.**—An exhibition of practical work executed by students of technical classes in the United Kingdom and the Colonies and by students at the institute's 1905 examinations will be inaugurated at the Imperial Institute (North Gallery) on Wednesday, the 28th inst., at 3.30, and will remain open until July 8. Earl Spencer will perform the opening ceremony.

**Personal.**—The council of the Society of Arts have, with the approval of the president, awarded the Albert Medal of the society for the present year to Lord Rayleigh "in recognition of the influence which his researches, directed to the increase of scientific knowledge, have had upon industrial progress, by facilitating, amongst other scientific applications, the provision of accurate electrical standards, the production of improved lenses, and the development of apparatus for sound signalling at sea."

**The American Institute.**—According to the *Electrical Review* of New York, the annual convention of the American Institute of Electrical Engineers is to be held at Asheville from the 19th to the 23rd of this month. A long list of papers is announced for discussion, some of which are, as usual, of only local interest, though others will be considered by a larger number of readers. It is said that "Coming events cast their shadows before," and when we find down for discussion such a paper as that by C. de Muralt on "Heavy Electric Freight Traction" we must begin to recognise that traction electrical is passing from the mere propulsion of light vehicles to general adaptation upon railways.

**Society of Arts.**—The annual conversazione will be held in the gardens of the Royal Botanic Society, Regent's Park, on Tuesday evening, the 4th prox., from 9 to 12 p m The gardens will be illuminated with coloured lamps and also by the Kitson incandescent oil light. The conservatory and the clubhouse will be open. The reception by Sir William Abney, chairman, and other members of the council, will be held at the entrance to the conservatory from 9 to 10 o'clock. The tropical house will be open to visitors. A selection of music will be performed by the string band of the Royal Artillery in the conservatory, and by the band of H.M. Grenadier Guards in the gardens. A concert and entertainment will be given from 10 to 10.45. Each member is entitled to a card for himself and a card for a lady. Additional tickets will be supplied to members or persons introduced by members at the price of 5s, which will be increased to 7s. 6d. on the day.

**Institution of Mechanical Engineers.** — The summer meeting of this institution, to be held at Liége, will commence on Monday next. A reception committee has been formed by the Liége Association of Engineers. The following papers have been offered for reading and discussion: "A Superheater applied to a Locomotive on the Belgian State Railways," by M. J. B. Flamme, of the Belgian State Railways, Brussels; "The Growth of Large Gas-Engines on the Continent," by M. Rodolphe Mathot (member), of Brussels; "Ferro-Concrete, and some of its most characteristic applications in Belgium," by M. Ed. Noaillon, of Chênée, Liége; "Colliery Electric Winding Engines," by M. Paul Habets, of Liége; "Strength of Columns," by Prof. W. E. Lilley (member), of Dublin; and "An Investigation to Determine the Effects of Steam-Jacketing upon the Efficiency of a Horizontal Compound Steam-Engine," by Mr. A. L. Mellanby, of Manchester. The tour will last until the 23rd inst., and a number of visits and other entertaining items have been arranged.

**The Tantalum Lamp.**—Dr. Bell and Prof. Puffer have been testing these lamps in the laboratory of the Massachusetts Institute of Technology. It is unnecessary to go into details, but six were in clear globes and four in frosted globes, and in the photometer tests six clear lamps gave an average of 22·20 c.p. at an average of 1·85 watts per candle. The four frosted lamps gave an average of 19·08 c.p. at a mean of 2 1 watts per candle. Corroborating this test, it is stated that Prof. Kennelly found a mean candle-power of 19 20 at 2·1 watts per candle-power. As regards life, the tantalum lamps stood for 800 hours with a mean candle-power of 20 at about 2·05 watts per candle, thus showing an effective life of about 16,000 candle hours. The observers say it is sufficiently obvious that if these lamps are anywhere nearly typical examples of the tantalum lamp, its life efficiency is so great as to entitle it to an immediate and important place in the art. Our reference is from an article on these tests in the *Electrical World and Engineer* of New York by the authors of the tests.

**Radiation from Ordinary Materials.**—An abstract of an article by Mr. Norman R. Campbell on his investigations into radiation from ordinary materials appears in the *Journal* of the Chemical Society. The author has measured the spontaneous saturation current (or "leak") through vessels of various forms and materials. It appears that the influence which the walls of a containing vessel exert on the spontaneous ionisation of the enclosed air is due to a radiation proceeding from the walls. Part of this radiation from certain materials, such as tin, zinc, graphite, and platinum, is analogous to the secondary radiation excited by Röntgen and other rays. The absorption coefficient of air for the radiation is comparable with that of air for the $\alpha$-radium rays, and is different for different materials. Hence the radiation is not likely to be due to radioactive impurities, but is probably an inherent property of the material. There is no evidence of rays from ordinary materials of a penetrating power considerably greater than that of the $\alpha$-rays from radioactive elements.

**Telegraphic Communication with the Continent.** The Association of Chambers of Commerce recently addressed the Postmaster-General, with a view to the establishment of additional cables between the United Kingdom and the Continent, and also more direct wires between the chief commercial centres for the distribution of telegrams. Lord Stanley has replied that additional facilities have been provided in recent years for telegraphic communication with the Continent not only by means of new cables, but also by the use of improved apparatus, rendering it possible to transmit two or more telegrams over one wire at the same time. Direct communication has also been arranged with many Continental towns which before could only be reached indirectly. As a result of these improvements he considered that the service was, on the whole, satisfactory. Such delays as took place were chiefly due to interruptions on the long Continental land lines used in connection with the service, which were unavoidable. Lord Stanley concluded by stating that the Post Office had under consideration the question of still further increasing by means of improved apparatus the number of channels available for communication, and he would not fail to take such other steps as might be practicable for maintaining the efficiency of the service.

**Ionisation by Radium.**—A paper is contributed to the *Comptes Rendus* by Mr. William Duane on the ionisation produced between parallel plates by radium emanation, of which an abstract appears in the *Journal* of the Chemical Society. Air containing radium emanation was introduced into a chamber containing two parallel plates, and the

Digitized by Google

ionisation current between the plates for a considerable difference of potential was determined: (1) immediately after the introduction of the emanation, (2) three hours later, and (3) half an hour after the emanation had been removed by a current of air. In the first case the observed current is due to the emanation, in the second to the sum of the effects of the emanation and of the imparted activity, and in the third case to the third substance, C, of the imparted activity. Formulæ are given showing the dependence of the current on the distance between the electrode plates in each of the three cases. Assuming that the charge on an ion is $3 \times 10^{-10}$ electrostatic units, the maximum number of ions of each sign produced by unit quantity of the emanation per second is $2{\cdot}1 \times 10^{9}$. It is also calculated that the energy involved in the production of the emanation from radium bromide corresponds with about one-twentieth of the total heat disengaged by the radium salt, and, further, that 14,500 ions of each sign are produced in the destruction of a molecule of emanation.

**Junior Institution of Engineers.**—The summer meeting of this association is this year to be of a special character in celebration of the society's coming of age. It is to be held earlier than usual, so as to include Foundation Day (June 30), and will open on Monday morning, the 26th inst., when the Lord Mayor and the sheriffs will receive the members in the Council-chamber of the Guildhall. The proceedings will include the reception of representatives of kindred associations; the presentation of a historical note by Mr. W. J. Tennant, past-chairman; a short address by the president, Mr. W. H. Lindley, of Frankfort-on-Maine; and votes of thanks, after which an adjournment will be made for luncheon. In the afternoon there will be a special visit of inspection of St. Paul's Cathedral, under the guidance of the Archdeacon of London and the consulting architect, Mr. Somers Clarke, followed by a choral service. The members are afterwards to be received by the Lord Mayor and Lady Mayoress at the Mansion House. On Tuesday both the morning and afternoon will be devoted to visiting Woolwich Arsenal, under arrangements specially made by Mr. H. F. Donaldson, chief superintendent of ordnance factories. In the evening a reception will be given by the institution at the Royal United Service Institution, Whitehall. For Wednesday, visits have been arranged to the Royal Mint; Messrs. Yarrow's works, Poplar; the North London Railway works, Bow; and the Greenwich generating station of the London County Council tramways (where the engines are in course of erection) and to the New Cross depôt. On the following day an excursion to Chatham will take place, for which the "Clacton Belle" has been chartered to leave London Bridge at 10 o'clock. On arrival at Chatham the dockyard will be visited, and the return to London will be *via* the Nore. Friday morning will be occupied with visits to Messrs. Doulton's potteries and to the Neasden power-house of the Metropolitan Railway. In the afternoon and evening the members and their friends will foregather at Earl's Court for an inspection of the Naval, Shipping, and Fisheries Exhibition, concluding with the inevitable dinner.

**Railway Electrification in South Africa.**—In our issue of Dec. 16 and Jan. 27 we alluded to the scheme which the Central South African Railways Administration, in conjunction with Messrs. Mordey and Dawbarn, had evolved for the electrification of the Springs-Randfontein section of their system. Messrs. Mordey and Dawbarn estimated that this would result in an economy of at least £40,000 per annum, without making any allowance for increased revenue due to improved service. It was stated that the administrators had only been deterred from adopting the scheme earlier by the question of raising the requisite capital, but it appeared that this difficulty had been overcome, as a large contracting firm agreed to undertake the work and accept payment out of profits by instalments. Notwithstanding this, the project has been shelved, though only, it is understood, pending an improvement in commercial conditions, which have latterly shown some indications in that direction. The possibility of the eventual introduction of electricity for operating a number of sections of the South African railways, and especially those where steep gradients occur, is, we hear, a constant subject of study on the part of the authorities, and the engineers of Cape Colony and Natal have made repeated efforts to devise powerful types of locomotives to cope with the geographical conditions obtaining on some of the routes. It is reported that the electrification of the short line from the Victoria Falls to Livingstone is on the eve of realisation; and with the immense quantity of power which the Falls may eventually provide for generating energy, it may be hoped that this will prove but the prelude to the electrification of Rhodesian railways on an extensive scale. In any case the electrification of South African railways is a possibility which electrical engineers will do well to keep in mind We observe, by the way, that at its meeting the other day the South African Intercolonial Council sanctioned a substantial vote for railway construction, which confirms the impression that commercial conditions in that quarter of the globe are on the up-grade, though the fact that the scheme was somewhat modified will act as a caution against forming premature anticipations.

**Trifles.**—The success of a factory or an installation or of an individual depends absolutely upon the appreciation of trifles. There are trifles which are important and there are trifles which are foolish, and the man who spends his time considering the latter is not of much account. It constitutes a difference between a success and a failure whether it is easily determined that the trifle is valueless or valuable. Perhaps in most industries it will be found that an industry has commenced by paying attention to points which were visible to everybody, but in the end the business has succeeded which has taken into account not only that which was originally seen, but that which was originally unseen. In gasworks the utilisation of by-products has proved in many cases salvation. In many factories a similar result has happened. In electrical works during the past 25 years a vast mass of what might be termed experimental work has been carried out; also a great deal of temporary work and large quantities of plant of one kind and another have been brought into play, but which have not fulfilled what may be termed their life's labour. What becomes of the old material, and how can it be best adapted for further use? These are questions which are oftentimes forgotten, but which when fully considered and successfully answered have given a small fortune to the person making the utilisation. The Americans are fairly keen in this direction, and have devised machinery for the getting out and the working up anew of old conductors. It has been suggested that there are many tons, probably, of old telephone and other wires used for electrical purposes at the present time existing as wasters, it being nobody's interest to do anything with this material. Perhaps with a little foresight circuits might be adapted so that if no longer required, the material used in them could be very cheaply turned to another purpose with corresponding advantage. At the end of the World's Fair at St. Louis, the United Railways Company of that city obtained a machine for putting braided cover on faded wire. The machine has been used for putting braided cover on a lot of underground cables, the insulation of which had been

Digitized by Google

removed. This is a sample, as we say, of making the best of a bad job, and might be successfully emulated.

**Testing of Electricity Meters.**—We alluded in our editorial columns last week to the subject of meters and to eight cases in which tests by London County Council inspectors had shown errors to have arisen in the charges made against the consumer. As the majority of these cases illustrate a particular point, it is worth while to give particulars of them: (1) The meter at the end of three months was over-read to the extent of 1,000 units, and at the end of the subsequent quarter, although the consumer had discontinued the use of the current, he was, as an outcome of the first misreading, charged for 9,000 units, making a total overcharge of 10,000 units, valued at about £85. (2) The meter was marked for 200 volts, but was used on a 100-volt circuit. During two quarters the supply company omitted to divide the readings by two, and the consumer was, therefore, charged double the correct amount. At the end of one quarter the meter was over-read by 100 units. The total overcharge resulting was £9. 0s. 4d. (3) Upon one consumer leaving a house and the supply being cut off, the meter was under-read by 100 units. This misreading was taken as the basis of the new tenant's consumption, and he was, therefore, overcharged by 100 units in his first quarter. (4) A 200-volt meter was used on a 100-volt circuit. The readings were not divided by two, and the total overcharge resulting was 100 per cent. of the correct amount for nine months. (5) The consumer had not been given the benefit of the maximum demand system. An overcharge of 80 units was the result. (6) The meter was incorrectly marked by the makers. The error was not discovered by the supply company. The consumer was consequently charged double the correct amount during the whole time the meter was installed, less the under registration owing to the meter running slow, which at the time of the test was found to be 21 per cent. (7) A similar case to the above. The meter was found to over-register the consumption 72 per cent. (8) The meter had been over-read by 100 units. The error was subsequently acknowledged by the supply company. It will be seen that in every instance except one the fault was not with the meter, but in the reading thereof. Thus, the chief difficulty lies, not in the fallibility of the instrument, but of that still more complex factor known to our Transatlantic friends as "the human equation." Even electricity meters do not quite attain to perfection, but, as we remarked last week, they are, in general, probably more accurate than any other class of measurements whatsoever.

**Commercial Conditions in South America.**—The lives of South American administrations have usually been of a brief order, and the authorities, realising the fact, have apparently acted on the principle that while their tenure lasts it shall at any rate be merry. One consequence of this has been that Europeans have had concessions repudiated with a levity that would be highly diverting were there not important interests at stake. Latterly there have been indications of the dawn of a more stable era for the revolution-ridden continent, and the example of Mexico lent encouragement to the hope that the Spanish republics have attained to a saner state of mind both in regard to self-government and the rights of those who invest money for the development of the natural resources of the country. It rather looks, however, as if one of the largest of these countries—Argentine—is lapsing into its old ways. In 1887 the City of Buenos Ayres Tramways Company acquired a concession, duly ratified by the National Congress, for a line of tramways along the front of the port. As far as the conditions permitted the company complied with the terms of the concession, but the condition of the roads prevented the whole of the system from being completed within the specified two years. A year or so ago the Anglo-Argentine Tramway Company, on taking over the property of the former company, applied to and obtained permission from the Municipality of Buenos Ayres to convert the lines to electric traction. Meanwhile, the Argentine Government granted to certain speculators a concession embracing the whole of this route, and issued a decree revoking the original concession, for which the City of Buenos Ayres Tramways Company paid £80,000, on the ground that the system had not been completed within the stipulated period. Three fácts are specially to be noted in this connection. The City of Buenos Ayres Company had performed their part of the covenant, so far as the conditions permitted; the Act of federalisation of the city of Buenos Ayres confers exclusive rights in such matters upon the Municipality, subject only to the National Congress; and neither the Municipality nor the National Congress have given their approval to the revocation of the original concession or the granting of a new one. The Anglo-Argentine Company, it may be remarked, have instituted proceedings for the protection of their rights; and by sticking to their guns they have a good chance of maintaining them, for experience has shown that if the arrogance of the South American republics be opposed by firmness it generally results in an ultimate climb-down on the part of the authorities. At the same time it is to be hoped that the latter will take a more rational view of the position, so that by judicious methods the ephemeral governments of the past may be replaced by a stable administration, enabling the great natural resources of the country to be developed.

**Telephony in Canada.**—In our issue of the 26th ult. we referred to the Government enquiry that was being held at Ottawa into the subject of telephonic control in the Dominion. We have received a further batch of the official reports, bringing the proceedings down to the 19th ult. The evidence, both documentary and oral, that has been considered by the Commission is of a voluminous character, and we can but indicate a few of the more notable features. Apparently, the Commissioners are taking pains to obtain complete information, as, in addition to extensive enquiries into the Canadian systems, those of Great Britain, the Continent, and the United States have come under review. A number of witnesses were examined in regard to rural lines. One of them stated that the farmers were so anxious for a telephone system that they supplied the timber for the poles and did the bulk of the transport work themselves; indeed, many of these rural lines, founded on the co-operative system, had somewhat primitive beginnings. In one instance a parish priest was the moving spirit in the formation of a rural line, to which he acted as electrical engineer. He thus described its history: "A telephone was needed to go from the presbytery up to the station on the Quebec and Lake St. John Railway, about two miles, and I interested the merchants. On the Lake St. John Railway the trains are sometimes very late, and there is no need to go to the station so much ahead of time. So we began building that small line with the help of the persons interested. Some of the merchants gave help in the shape of hauling the poles and also erecting them. They sent their serving men. It was not a long work; it only took four or five days to build the line." The cost of construction naturally varied in different cases, but one witness put the cost for a fairly typical line, with two instruments to the mile, at £45 per mile. It appears, however, from the testimony of Mr. J. H. Winfield, manager of the Nova Scotia Telephone

Digitized by Google

Company, that, while many of the farmers are willing to use the lines, they are not always prepared to pay for the accommodation. The company offered to construct a certain rural line for the benefit of the farmers if a stipulated number of them subscribed. After some time the necessary number came along, when it was discovered that half a dozen farmers, by putting together a small sum, were having the benefit of each instrument. Notwithstanding this, the company is one of the most prosperous telephone concerns in the Dominion. It ousted the Bell Company, and now has one subscriber in 74 per head of population, which is the best average in Canada, while its subscribers are increasing at the rate of 300 per annum. Subsequently, Mr. C. F. Sise, president of the Bell Company, was examined in detail as to the financial and general position of that company. The Canadian section of this concern was founded in 1880, and during the first year the receipts amounted to £6,000 against an expenditure of £3,800. These figures were more than trebled during the following year, the receipts and expenditure advancing in substantially the same ratio. For the year ending Dec. 31 last the receipts totalled some £600,000, the expenses being £420,000. The increase has been progressive from year to year. An Act passed in 1902 confers power on the Governor in Council to vary the company's rates on the application of any interested municipality. No application under this Act appears to have been made. Evidence was given by some of the witnesses as to the obstructive tactics of the Bell Company, but this state of affairs has not been universal, the Bell Company having in some instances co operated with other concerns, apparently when the latter were well established. The Railway Act of 1903 vetoes exclusive privileges to any telephone company in regard to installations at railway stations, but the Bell Company appear to still have a substantial monopoly of the stations on the Grand Trunk and the Canadian Pacific lines, though a few local telephone companies have latterly been admitted. An interesting witness was afterwards examined in Mr. H. Laws Webb, of London, details of whose evidence are not yet to hand.

**Insulation Resistance of High-Tension Cable Coverings.**—The results of some tests carried out in Messrs. Felten and Guilleaume's laboratories on various qualities of impregnated paper-insulated cables are described by P. Humann in a recent number of the *Elektrotechnische Zeitschrift*, and serve to emphasise the fact once more that high insulation resistance by itself forms no guide to the practical utility of a cable. Cable specifications requiring guarantees of excessive insulation resistances are still constantly met with, and these requirements can be readily complied with by the cablemakers by the employment of solid impregnating substances amongst other methods, but generally at the expense of flexibility in the insulating covering. The cracking of a single layer of insulation in a cable insulated with a large number of layers of impregnated paper will greatly facilitate the breakdown of the whole insulation, just as in the case of a sheet of glass a fine scratch with a diamond is found greatly to reduce the breakdown voltage. For this reason soft and flexible coverings are essential, and this is only possible, in the case of paper-covered cables, if the impregnating materials consist largely of oils. This involves a lower insulation resistance, but gives a reliable and easily laid cable. It is often supposed that a high insulation resistance means a reduction in the dielectric losses at high tensions. That this is not the case is clearly shown by the following measurement of dielectric losses in two three-phase cables differing greatly in their insulation resistances. The cables were 5,000-volt lead-covered ones, and each contained three 25 square millimetre conductors. In each case the losses between the three phases and the lead covering were measured by means of a mirror wattmeter.

| No. 1 Cable.—1 280 megohms per kilometre; ·284 microfarads per kilometre. | | No. 2 Cable.—10,850 megohms per kilometre; ·282 microfarads per kilometre. | |
|---|---|---|---|
| Voltage. | Loss in watts per kilometre. | Voltage. | Loss in watts per kilometre. |
| 2,745 | 13·38 | 3,200 | 16·4 |
| 4,160 | 30·7 | 4,000 | 25·4 |
| 5,220 | 48·35 | 4,800 | 36·3 |
| 6,260 | 69·3 | 5,600 | 49·5 |
| 7,470 | 99·8 | 6,400 | 64·8 |
| 8,540 | 129·4 | 7,200 | 84·1 |
| 10,270 | 195·7 | 8,000 | 100·4 |
| 11,470 | 243·8 | | |

The tests were made at 53 ~. The alternator employed did not give a sinusoidal E.M.F. curve, so that the figures can only be considered as relatively correct. It will be seen that the difference between the two cables amounts to only about 10 per cent., and allowing for errors of observation, the two cables can well be assumed to have equal losses, and yet the insulation resistance of cable No. 2 was about 8½ times as great as that of No. 1. These results only apply to properly dried cables. If the drying process is only partially completed, reduced insulation resistance can be experimentally shown to lead to increased dielectric losses. In general, therefore, it may be taken that with properly dried cables the dielectric losses are not influenced appreciably by the insulation resistance, but that in cables having low insulation resistances due to incomplete drying out the losses increase decidedly as the resistance falls. In order to permit proper mechanical strength and flexibility to be obtained, the specification of excessive insulation resistances of several thousand megohms should be avoided, for a 300-megohm cable may have quite as good all-round qualities as one of 1,500 megohms, and better qualities than one of still higher resistance. The measurement of insulation resistance should, in fact, only be employed to indicate whether the cable has some actual fault of construction.

**The Telephone Transfer.**—Chief interest in the enquiry which the House of Commons Committee is conducting into the purchase agreement between the Postmaster-General and the National Telephone Company centered last week in the evidence of Mr. W. S. Gaine, the manager of the company. He stated that the company was now working in 280 telephone areas. At the end of March last they had 1,139 exchanges, 320,017 subscribers telephones, and 5,365 public call offices. In 1890 the capital of the company was £2,589,000, and it had grown to £10,840,000 in 1904. The net revenue had increased from £191,000 to £759,000. The total wire mileage was 728,000 miles, and the messages sent over the wires per annum numbered 995,000,000. The average age of the plant at the end of last year was only about four years. He claimed that the company had shown enterprise in the conduct of their business. The greatest development of telephone service had taken place in New York, although the charges there were approximately three times higher than in this country. He considered that the agreement was of great value to the public, because it encouraged the company to push and develop the service up to the last day of the license. The view of the directors was that the Postmaster-General had driven a very hard bargain, because it gave no consideration in respect of the goodwill of the great business which the company had built up. The company had had to pay for all the experiments and mistakes which were associated with the development of a new industry, and a sum of £1,848,000 had already been paid in royalties to the Post

Digitized by Google

Office. Yet the Post Office was going to step into this business in 1911 on paying only for the plant employed in it. The company had never obtained assistance from the Post Office, so far as he knew, without having to pay for it; on the contrary, every impediment had been put in the way of the company. In spite of every impediment, however, the company had developed a most useful public service to a high point both in extent and efficiency. Mr. Gaine charged the London County Council in particular with having retarded the telephone service of the Metropolis. He stated that if the provincial municipalities had not taken a much more enlightened view than the London County Council, the telephone service would not have developed generally throughout the provinces to the extent it had done; but, fortunately, he had been able to make arrangements with the local authorities of the great towns in England, and most of those in Scotland, with the result that the plant in those towns had been practically reconstructed and placed underground. He regarded as unreasonable the provision in the agreement to the effect that the Postmaster-General should have the right to pick and choose plant at the end of the license. Replying to a question by Sir William Holland, Mr. Gaine stated that the rate which gave unlimited service had every disadvantage that could be thought of, and ought not to be maintained, or, at any rate, lowered. In reply to another question as to whether there was a lower rate in places where there was a municipal exchange, he replied in the negative. The unlimited service rate had never been altered in any of such places, but additional rates and tariffs had been brought into being very largely to meet the exigencies of competition. Mr. Gaine thus expressed this part of the situation: "We cannot engage in a fight with gloves on, and I may add that I have met the competition in an extremely successful way." He did not think he was exaggerating in stating that municipal telephony had proved a failure. There was only one case of important competition — Glasgow. His own view was that the Glasgow Corporation before long would be very sorry that they had embarked upon it. The splitting up of the administration of this service did not lead to greater economy. He did not know whether the Post Office would conduct the business more economically than the company was now doing, but he was sceptical on the point. At the conclusion of his evidence Mr. Gaine requested that he should have an opportunity of replying to the statements of witnesses representing local authorities, to which the chairman replied that the request must be made later. The committee then adjourned until after the Whitsuntide recess.

**Cable Rates to the East.**—The Chancellor of the Exchequer last week received a deputation of representatives of chambers of commerce on the question of a further reduction in the cable rates to India, China, and West Africa. The deputation, which was introduced by Sir Edward Sassoon, included Sir William Houldsworth (chairman of the Commerce Committee of the House of Commons), Sir W H. Holland (president of the Association of Chambers of Commerce), Mr. Henniker Heaton, Sir Alfred Jones, and representatives from London, Liverpool, Belfast, Blackburn, Bury, Dundee, Newcastle, Newport, Wolverhampton, Glasgow, Leith, Sheffield, and Bradford. The Government, it may be mentioned, has an opportunity of considering and readjusting the cable rates charged by the various companies when the landing rights of these companies are renewed by Government grant. Sir Edward Sassoon urged the reduction of cable rates to India from 2s. 6d. to 1s. 6d. per word, a reduction of 25 per cent. on the charges to West Africa, and an amelioration of the rates to China. The deputation was present in no hostile spirit to the private cable companies, but it was desired that the State should enter more into the provision for adequate cable facilities. He quoted the Viceroy of India to the effect that the reduction made in the Indian rates some three years ago had resulted in a large increase of cable traffic. In reply to a question from the Chancellor of the Exchequer as to how any losses were to be met, Sir Edward replied that, if the Government did the business properly, there would be no loss. Sir Alfred Jones stated that cablegrams could be sent from France to Africa at about a quarter of the English rates. Mr. Henniker Heaton expressed a hope that the Chancellor of the Exchequer would appoint a committee to report on the whole question. Mr. Chamberlain, in reply, said that cable companies had shown enterprise, skill, and public spirit, and he was glad to see that this fact was recognised. At the same time the Government might, under special conditions, itself aid in the construction of cables, though he would never choose Government enterprise in these matters where private enterprise showed itself able and willing to undertake the work. He thought it would be doing ill service to the cause of cable telegraphic expansion if the Government lessened the inducement to private enterprise, or harassed or frightened such enterprise by Government competition. It did not follow that increase in traffic brought an increase in profit to the owners of the cables, because it might happen in that case that other cables would have to be laid down at considerable expense. In regard to charges, it was not fair to take mileage simply as a basis, because it was in some areas more expensive to construct the cable and more costly to work it than in others. Dealing with the rates charged by France to its West African possessions, Mr. Chamberlain stated that he did not think that, on the average, British rates compared unfavourably with our neighbours. In reference to the rates to and from India, the Chancellor remarked that the rates were reduced from 4s to 2s. 6d. from March 1, 1902. He did not think the great increase of traffic to India had been altogether caused by the reduction in rates. At the same time, he was very glad to be in a position to inform the deputation that in pursuance of the arrangement of 1902, by which in the first place the rate was reduced from 4s. to 2s. 6d., that a further reduction would be made by Oct. 1 next from 2s. 6d. to 2s. Although that would involve further favours on the part of the Indian Government in pursuance of their guarantee, he hoped and believed that the response of the traffic to the reduction might be sufficient in a short time to relieve them of any additional burden. Regarding the Pacific cable, he thought it would be inopportune for him to discuss the question at the present juncture, the matter being virtually *sub judice*, as the much-deferred conference would be opened in a few days. He did not think it desirable to appoint a further committee at the present time. Such a committee could not usefully go again over the ground covered with so much care and ability by Lord Balfour of Burleigh's Committee. From time to time, as opportunity occurred, the Government would do its best to secure improved communication between the different portions of the British Empire, but he did not think the necessity was proved at the present time for the Government itself to embark upon further great cable enterprise. In his opinion, any capital expenditure by the Government in that direction would be received with great dislike by many. It would adversely affect the Government's credit, and it would tend to check the return of commercial and financial prosperity. In conclusion, Mr. Chamberlain stated that it was hoped that the rate to Egypt would very shortly be reduced to 1s. a word.

## WIDNES AND RUNCORN TRANSPORTER BRIDGE.

This transporter bridge across the Mersey was recently opened by Sir John Brunner, M.P., and forms a most useful connection between the towns of Widnes and Runcorn. The bridge is of the "transporter" type, and is in design precisely similar to an ordinary stiffened suspension bridge, with the exception that the approaches to the bridge are at a low level—thus dispensing with the very costly high-level approaches—and the traffic, both foot and wheel, is carried over in a car suspended to the underside of the bridge. This principle was designed by Mr. Charles Smith, of Hartlepool, who planned a bridge of this type about 30 years ago for crossing the River Tees at Middlesbrough, but it was never constructed. Several bridges of this type have been since built on the Continent, but the general construction of these bridges is entirely different from the Widnes and Runcorn Bridge, the principle only being the same.

FIG. 1.—View of the Widnes Tower and Bridge, End on, showing the Engine Room and Car.

By a coincidence, and not from design, the Widnes and Runcorn Bridge is on exactly the same site as the one proposed by Telford, and is of exactly the same span—viz, 1,000ft. between the centres of the towers. The bridge is approached on the Runcorn side from Waterloo-road, and on the Widnes side from Mersey-road, the approaches consisting of new roadways at an improved level, nearly flat, built between stone and concrete retaining walls as far as the water's edge. The two main towers carrying the cables and the stiffening girders are built, one on the south side of the Ship Canal and the other on the foreshore on the north bank of the river, and are approached from the above earthwork approaches by steel elliptical girders resting on cast-iron columns carrying a corrugated steel flooring, upon which are laid the timber blocks on concrete, forming a roadway 35ft. wide between the parapets, the footpaths being 6ft. wide each. The roadway in front of the towers is widened out to 70ft. for marshalling the traffic, and for providing space for waiting-rooms, etc.

The transporter car (Fig. 1) consists of a platform 55ft. long by 24ft. wide, and is suspended from the trolley by steel-wire ropes, so hung that they prevent either side or end oscillation of the car. The car is capable of holding at one time four two-horse farmers' wagons, loaded, and 300 passengers, the latter being protected from the weather by a glazed shelter, with folding doors at the ends and side. On the top of the car is fixed the operator's cabin, in which is placed the switchboard, so that the operator has a full view of the course, and has the car quite at his command; he can thus reverse, go ahead, or put on the brakes at a moment's notice. The time occupied by the car in crossing is about 2¼ minutes; so allowing the time for loading and unloading, it is capable of making about nine or ten trips per hour. The bridge, approaches, and car are electrically lighted, and fog signals and bells are sounded when necessary. The bottom of the car is about 12ft. above high-water level, and clears the Ship Canal wall by about 4ft. 6in.

With the construction of the towers, the steel-wire girders, the anchorages, and the stiffening girders we do not propose to deal at the present time, as we are chiefly concerned with the moving portion of the bridge—*i e*, the transporter. This is carried from the lower flanges of the stiffening girders (Figs. 2 and 3), on which are fixed the rails, upon which runs the trolley, from which is suspended the car. The trolley is about 77ft. long, and is carried by 16 wheels on each rail. It is propelled by two electric motors of about 35 b h.p. each, a large excess of propelling power being provided, partly for economy of working and principally to be ready for any emergency of strong head winds with heavy load. The motors are fixed to a kind of bogie arrangement in the trolley, so that in the case of large curvature of the bottom boom of the stiffening girders, due to either temperature or load, the driving wheels would be certain to be hard on the rails. Efficient automatic and hand brakes are fixed, so that it will be possible to pull up the car within its own length when going full speed. This transporter is worked electrically, and the whole of the plant required was supplied by Messrs. Mather and Platt, Limited, of Salford Ironworks, Manchester. This firm

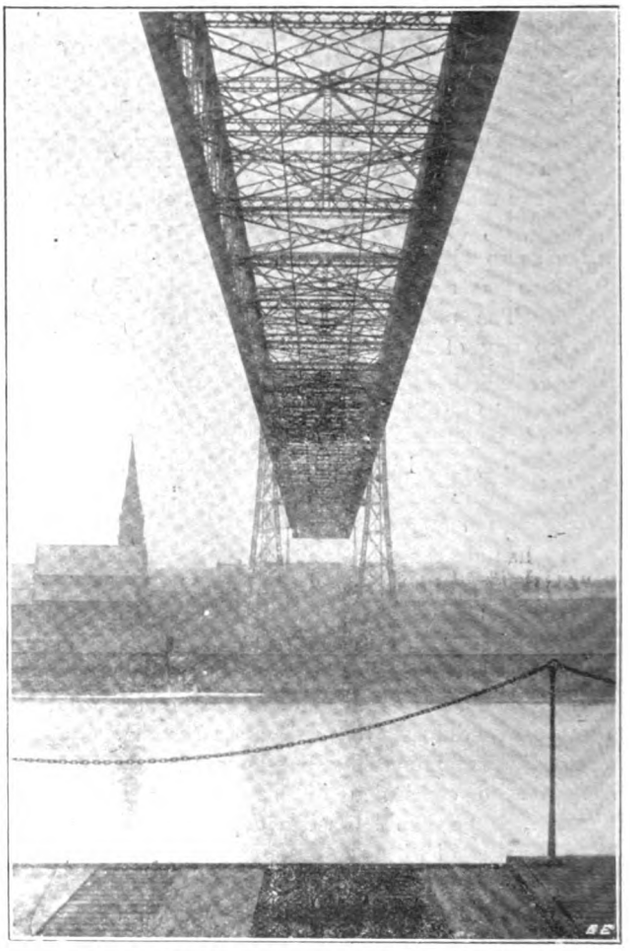

FIG. 2.—View of the Underside of the Main Boom, showing the Conductor Rails below the Cross Girders.

have made a special study of the electrical working of bridges, two swingbridges over the River Weaver, as well as the rolling bascule bridge at Barking, having been equipped with electrical plant by them; and the experience

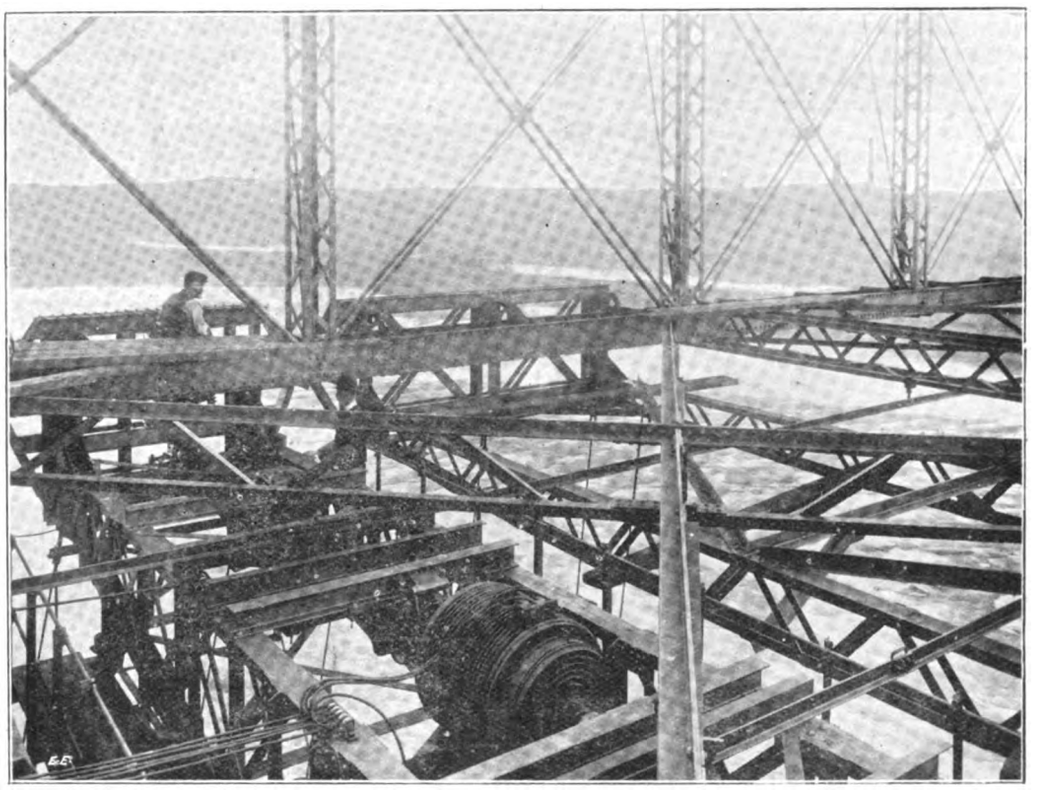

FIG. 3.—View of one of the Trolleys, showing the Entirely Enclosed Motor and Gear.

gained has enabled them to introduce improvements on the methods previously used in the case of transporter bridges such as that at Rouen.

The engine-house (Fig. 4) is erected within the left-hand tower on the Widnes side of the river, and contains the

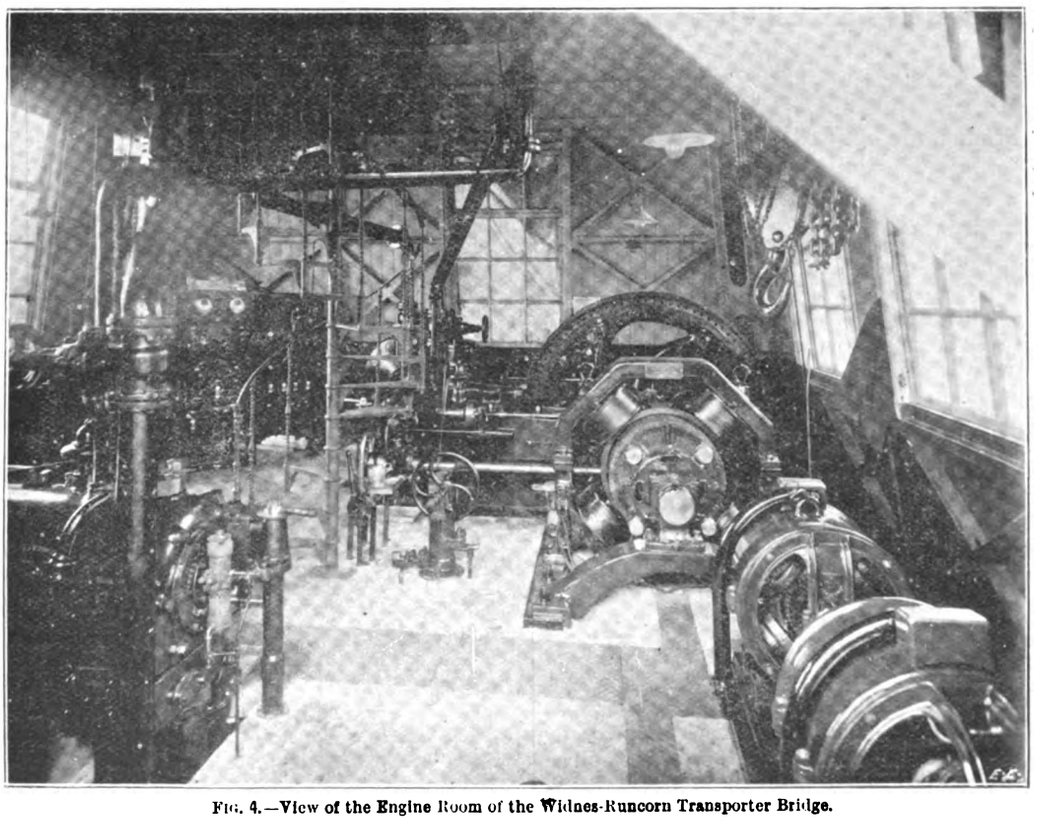

FIG. 4.—View of the Engine Room of the Widnes-Runcorn Transporter Bridge.

whole generating plant, which comprises two gas-engines, made by Messrs. Crossley Bros., Limited, for Messrs. Mather and Platt, Limited, each capable of developing 75 b.h.p. when running at a speed of 210 revolutions per minute, the gas being supplied from the Widnes town gas-mains. These engines have cylinders 16in. in diameter with a stroke of 21in., and are fitted with the usual silencers and water-cooling pipes, the water supply being obtained from a large tank fixed at the top of the engine-house. To each engine is directly coupled a Mather and Platt multipolar dynamo of 45 kw. capacity, capable of giving a continuous output of 90 amperes at a pressure of 525 volts when running at 210 revolutions per minute. The engine-room also contains a booster, consisting of motor and generator directly coupled, and used for boosting the pressure when charging the accumulators, and also for maintaining the voltage on the line, and equalising the load

Digitized by Google

on the generating dynamos. The accumulator (Fig. 5) referred to is placed in a room above the engine-room, and consists of 245 cells supplied by the Chloride Electric Storage Company, having a capacity of 90 amperes for one hour. The cells are mounted on insulators carried on suitable stands. In the corner of the engine-room is the switchboard, arranged with three panels—one for the dynamos, with the necessary main and regulating switches and measuring instruments; the second for the accumulator cells and booster similarly fitted up; and the third panel for the feeding and lighting circuits.

From the switchboard the two main supply cables are led up by the tower and across on to the main girders of the bridge, where they are attached to two overhead T-shaped conductors, which are carried by insulators below the cross girders of the bridge, and from which the current is collected by trolley arms, and thence passes down to the controlling apparatus in the driver's cabin, placed on the top of the transporter car. The regulating apparatus consists of a circular type controller, by means of which the starting, regulating, and stopping of the motors on the travelling trolleys is effected. From the controller cabin to Messrs. W. Thornton and Sons, Liverpool; the contract for the steel superstructure being let to Arrol's Bridge and Roof Company, Glasgow, who sublet the sinking of the cylinders, greenheart fenders and scaffolding to Messrs. Holme and King, Liverpool. The construction of the towers, approach girders, and cylinder foundation was sublet to the Widnes Foundry Company. The construction of the steel cables was let to the St. Helens Cable Company. The whole of the electric installation and equipment, including the lighting of the structure, is being carried out by Messrs. Mather and Platt, of Salford Iron-works, Manchester.

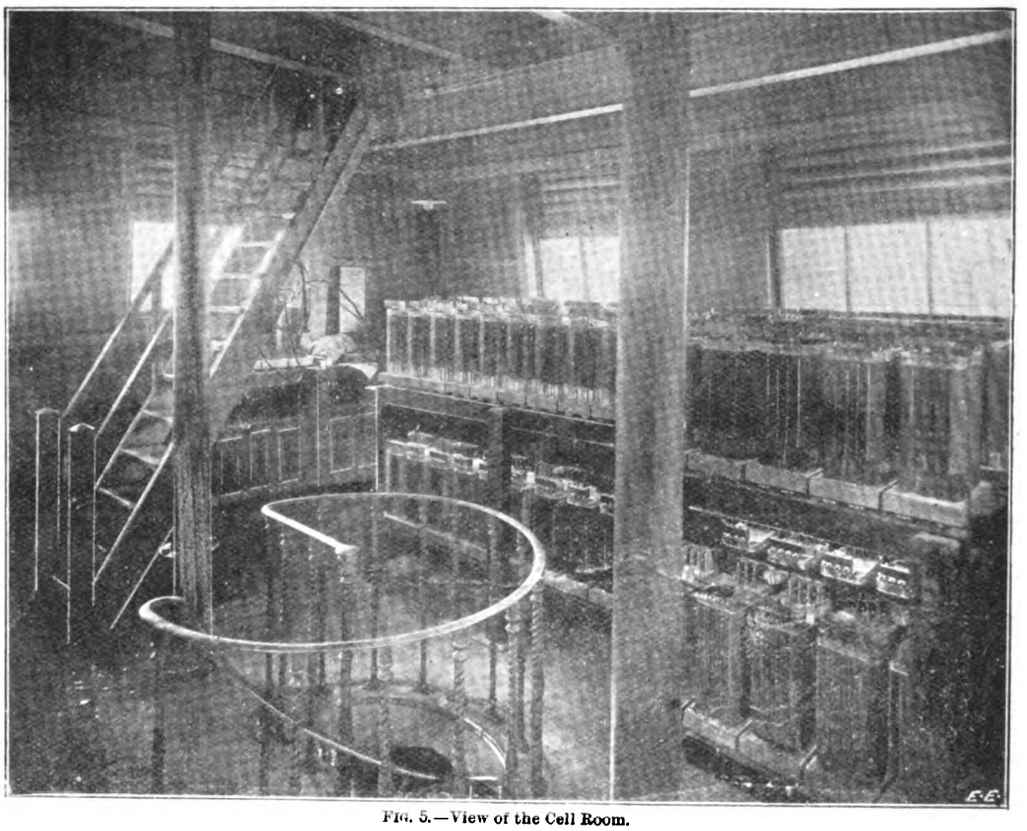

FIG. 5.—View of the Cell Room.

the wires are led straight up to the motors fixed on cross girders connecting the pairs of trolleys, which run on each of the continuous main girders of the bridge. The motors are of Messrs. Mather and Platt's steel-clad entirely-enclosed type, and are each capable of developing 36 b.h.p. when supplied with current at a pressure of 500 volts. They drive by means of gearing and shafts the two driving wheels of the trolleys, and are arranged also to act as brakes for stopping the car. The control cabin also contains a small switchboard with the requisite switches and instruments for the information of the driver.

In addition to supplying the plant for the power, Messrs. Mather and Platt, Limited, have also supplied and erected the whole of the electric lighting of the bridge. This consists of five arc lamps in each of the four lanterns at the summits of the towers, incandescent lamps in standards on the approach roads on either side of the river, as well as the necessary lights on the car itself, and in the waiting-rooms and offices on the landing stages.

The consulting engineers for the whole of the work have been Mr. John J. Webster, M.I.C.E., of Westminster, and Mr. John T. Wood, M.I.C.E, of Liverpool; the resident engineer being Mr. L. H. Chase, M.I.C.E. The contract for the masonry in the approaches and anchorages was let

## A STUDY OF SHORT-DISTANCE TELEPHONY.

BY VALENTINE RYAN.

(*Concluded from page 812.*)

The connections for a rather improved design of intermediate switch are shown in Fig. 10. A cylindrical piece of ebonite is mounted on the switch spindle, around which is fastened a brass sleeve divided into four equal parts, the switch terminals being connected to six brass strips which make contact with the split ring. When the position of the switch lever is changed, the split ring moves with it, thus altering the connections as desired. In Fig. 10 the switch

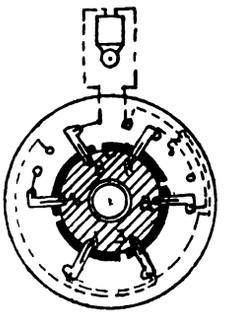

FIG. 10.—Back of Intermediate Switch in Centre Position. 1, 2, 3, contact pieces connected to line terminals; B, B, ditto to bell terminals; R, ditto to return wire; dotted lines show internal wiring of switch.

is shown in the centre or "through" position, the intermediate station is disconnected, and the outer ones are engaged in conversation with the extension bell in circuit. This switch can be arranged to reverse the battery con-

Digitized by Google

nections, thus enabling those at the outer stations to be connected in series, and so avoiding the trouble caused by the reversing switch mentioned above. To do this the switch should be made somewhat bigger, and a smaller split ring mounted in a similar manner and concentric with the one described, this split ring having two parts, with four brass strips making connection with it—one each for the telephone and return wire, and a pair for the battery, it being arranged to reverse the battery connections as the switch lever is placed in the right or left hand positions. Otherwise the switch would be the same as before, these latter connections being independent of the former ones. Usually the arrangement of the instruments at the intermediate station does not combine to form an imposing station, and the local wiring does not add to its appearance. It would be a decided improvement, and there are no objections in the way, if all the apparatus was made combined in a single casing with a micro-telephone. The cost would be slightly reduced, and the local wiring would be dispensed with, which is an advantage in many ways.

A system that is frequently required for hotels and other large buildings consists of a number of stations arranged to communicate with a central station only. This system is often erected in commercial establishments for the use of the employés generally, as was previously mentioned. The accompanying diagram (Fig. 11) illustrates five direct working telephones, arranged to communicate with a central station. When one of the outer stations rings up the central station, the numbers on the bell indicator move;

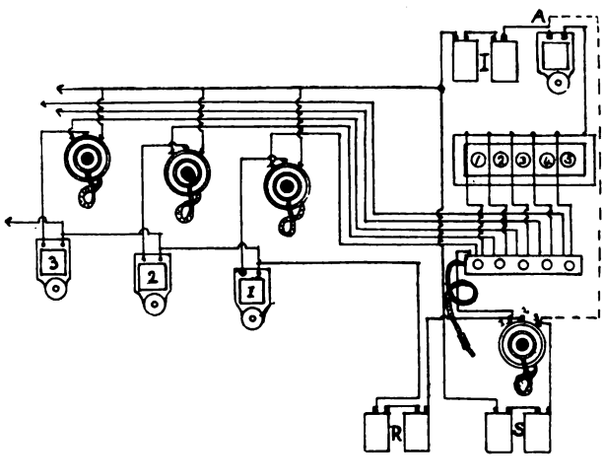

FIG. 11.—Five Stations arranged to Communicate with a Central Station.

the plug is then placed in the corresponding hole of the line selector. This plug separates the lugs of a V-shaped spring, which breaks this particular bell circuit and also completes the connection with the home telephone. The rest of the bell circuits remain complete, so that a call can be received at any time without interrupting the conversation. Many persons would prefer a number of two-point switches for line selectors instead of a plug-board; they may also be more familiar with the "reply and call" system, which is used for much the same purpose. In the latter a battery and a switch must be provided at each station, and in using direct working telephones these may be confined to the central station. With the latter any bell installation can be readily and cheaply converted into a telephone one, all that is necessary being to replace the bell pushes with the telephone and add a telephone and line selector at the indicator. When bells are required at the outer stations, a third wire, common to all bells, must be erected.

In the diagram (Fig. 11) three batteries are shown. The battery S is used exclusively for speaking; R may be called the ringing battery, and is employed for signalling to the sub-stations; I, the indicator battery, is used by the sub-stations to ring up the central station. Except in some installations where the change has been initiated by the writer, this battery, I, is not used. The second terminal, A, of the bell is connected to the terminal marked 3 on the telephone, as shown by the dotted line, and then a person at a third station can overhear, and, if they choose, join in, the conversation. When strangers are using the system, as in hotels, for which the arrangement is particularly adapted, this would lead to confusion. It is interesting to observe how this happens. If the connections are traced out, they may be reduced to those shown in Fig. 12. Suppose A and B to be engaged in conversation, and C a third station, X and Y are the bell and indicator coils respectively. Then across the battery terminals there are two circuits in parallel. In practice the resistance of these circuits often happens to be equal, the resistance of X and Y in the overhearing circuit helping to make up the resistance of the second telephone in the speaking circuit, direct working receivers having a resistance of, say, six ohms.

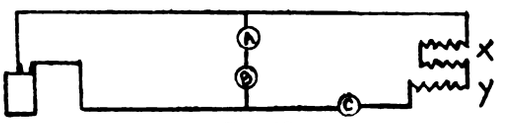

FIG. 12.

Now, as the current fluctuates in one circuit, a corresponding variation is produced in the other. To overcome this disadvantage, the third battery, I (Fig. 11), was introduced; when the connections are traced out, they will reduce to those shown in Fig. 13. The overhearing station, C, can complete a circuit as before, but it has the indicator battery, I, in it, not the speaking battery, S; the latter is completely under the control of the central station. At first sight three sets of cells may appear clumsy, but they can be used to work a large installation, even when the number of stations approach 30; anyhow, a far larger number would be required if induction-coil instruments were employed. If a fault occurs on the installation, each battery being used for a separate purpose, they are an advantage in helping to locate it.

With the receivers in position as shown, the terminals marked 1 and 2 are connected; press the push-button and 1 and 3 are connected; when speaking, the receiver and transmitter are connected in series across 1 and 3. At the central station it will be noticed that one pole of the ringing battery, R, is connected to the centre terminal of the telephone. The internal wiring of this instrument is different from the rest, and when the button is pressed, terminals 1 and 2 are connected, and not 1 and 3, as in all other instruments.

The stations arranged on this system have a common return wire, and induction may lead to overhearing in much the same way as with an intercommunication one; it lends itself to overcoming this disadvantage in an original manner. Suppose, for the moment, A and B (Fig. 13) to be engaged in conversation, and C, at a third station, to place the receiver to his ear, then there are two complete circuits as shown. A and B complete a circuit through S, and C through the battery, I; in each there will be a primary current—that in C will be weaker and more constant in strength than the other. The batteries are shown connected up in the opposite ways. Hence, if along any portion of the common return wire both currents pass, they will be flowing in the same direction, and the current in C will not interfere with the speaking. The induced

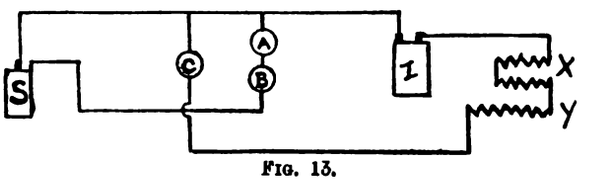

FIG. 13.

current in the circuit C is due to the fluctuation of the current caused by the speaking in A and B, and will be in the opposite direction to the primary current in the same circuit. This induced current will be neutralised by the primary current—it follows there will be no overhearing. The connections on the central-station system (Fig. 11) are arranged on this plan. The writer has not had an opportunity of testing this in practice, while experience in such matters tempts him to hesitate before pronouncing this system as private; anyhow, it certainly is a sound practical approach to being so. If a little discretion was used in erecting such a system, it could be arranged to be a secret one. The development of the principles embodied in the above system offers a promising scope for ingenuity.

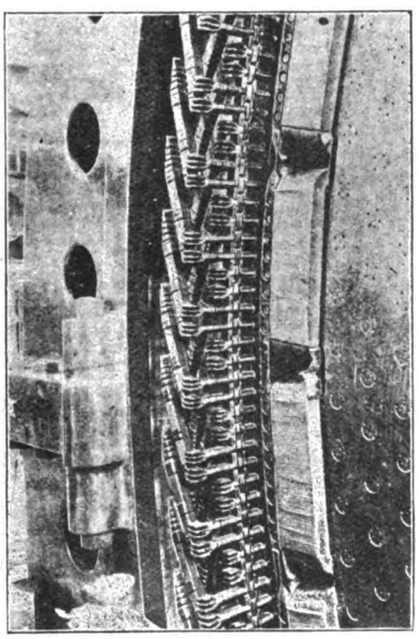
Digitized by Google

Owing to the situation of telephone stations varying so much, and hence the relative position of the wires in which the induction takes place, diagrams of systems of connections under any circumstances are hardly qualified to be called private.

## TEST OF A 5,000-KW. ALTERNATOR.*

BY L. L. GAILLARD.

The following paper is intended to give a general description of the series of tests made on each of the alternators installed in the Seventy-fourth-street, Manhattan, power station of the Interborough Rapid Transit Company, of New York City. The object of the tests was to obtain characteristic curves of the machines and to determine how nearly they conformed to the contract requirements and the manufacturer's guarantee. Each machine is a 5,000-kw., 11,000-volt, 25-cycle, 75-revolutions-per-minute Westinghouse alternator, direct connected to a double horizontal-vertical Allis compound engine. It may be well to preface the account of the tests with the following extracts from the contract specifications, giving certain data obtained from the calculations of the manufacturer, and certain guarantees upon



Armature End Connections, showing the Wooden Block Bracing between the Coils.

which was based the acceptance or rejection of the machine by the purchaser:

A guaranteed full-load efficiency of 96·5 per cent., to meet which guarantee the total permissible losses in the alternator are therefore 181,300 watts.

| | | |
|---|---|---|
| The full-load field current equals | 202 | amps. |
| The full-load armature current equals | 263 | amps. |
| The armature copper loss equals: $263^2 \times 0{\cdot}4 =$ | 27,667 | watts. |
| The field resistance equals | 0·85 | ohms. |
| The resistance of the armature equals | 0·4 | ohms. |
| The field copper loss equals: $202^2 \times 0{\cdot}85 =$ | 34,683 | watts. |
| Total copper losses = | 62,350 | watts. |
| Total allowable iron losses, based on 96·5 per cent. full load efficiency = | 118,950 | watts. |

The efficiency on non-inductive load will be:

| | |
|---|---|
| At one-quarter load = not less than | 90·00 per cent. |
| At one-half load = not less than | 94·50 ,, |
| At three-quarters load = not less than | 95·50 ,, |
| At full load = not less than | 96·50 ,, |
| At 25 per cent. overload = not less than | 97·00 ,, |

The efficiencies are based on $I^2R$ loss in the armature and field coils and on the armature iron loss. Friction is not included.

The current in the armature when short-circuited with normal no-load field current, will equal three times full-load current.

The regulation at 100 per cent. power factor will equal 6 per cent.

After running for 24 hours at full load at 100 per cent. power factor, the rise in temperature in no part will exceed 35deg. C.; and at 25 per cent. greater load, with the same power factor, for 24 hours, the rise in temperature will not exceed 45deg. C.

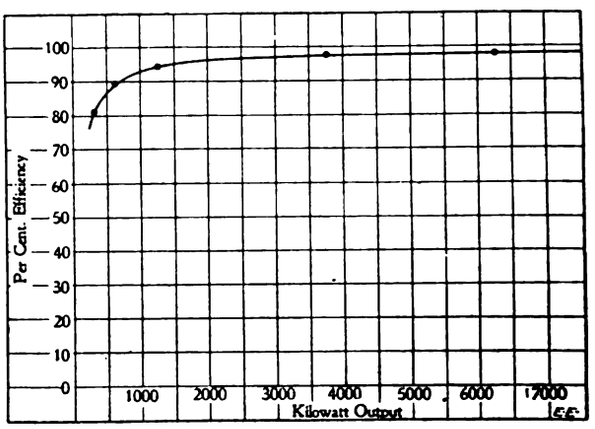
* Reproduced from the *Electric Club Journal*.

The following measurements and tests were made on the alternator: measurement of armature iron loss; resistance of armature winding; resistance of field winding; $I^2R$ loss in armature; $I^2R$ loss in field; efficiency at various loads; no-load saturation curve; short-circuit characteristic; regulation (calculated); insulation puncture test; temperature rise under load.

Laminated Ring and Clamping Device for determining the Quality of the Iron used in the Manhattan Alternators, and thus the Total Iron Loss.

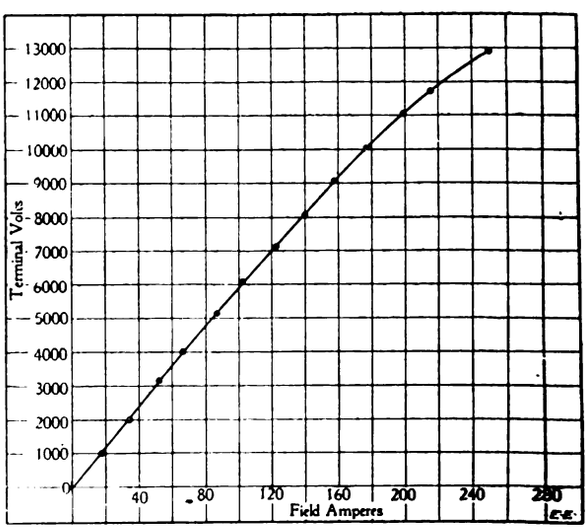
*Armature Iron Loss.*—It being entirely impracticable to measure this loss in the usual manner, the following interesting method was adopted. The alternator armature is built up of the following amounts of sheet steel worked at magnetic inductions given below:

| | | | | | |
|---|---|---|---|---|---|
| 234 000 cu. in., | 90 per cent. | solid, | at 65,500 | C.G.S. lines per | sq. in. |
| 16,500 ,, | ,, | | at 91,100 | ,, | ,, |
| 20,300 ,, | ,, | | at 76,500 | ,, | ,, |



Efficiency Curve of a 5,000-kw. 11,000-volt Manhattan Alternator.

The iron losses were determined from a measurement of the losses in sample rings made from the material of which the armature was built up. These samples were annealed in the ovens with the armature laminations, were



Running Saturation of a 5,000-kw. 11,000-volt Manhattan Alternator.

painted the same as these laminations, and then built up into test rings and compressed until their volume contained 90 per cent. solid metal. The rings were then wound for test purposes, and the losses at the different inductions mentioned above were measured with a sensitive wattmeter.

Digitized by Google

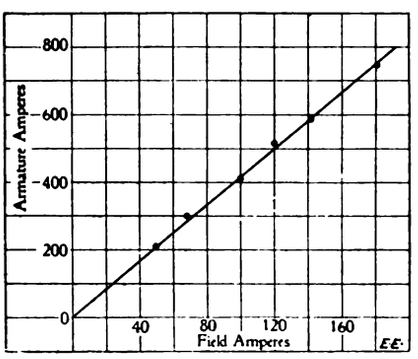
The dimensions of the test samples were: outside diameter, 12in.; inside diameter, 8in.; thickness (compressed to 90 per cent. solid), 2in.; cross-section, 2in. by 2in., four square inches; mean circumference, 31·416in.; volume, 125 66 cubic inches. The calculation of 90 per cent. solid material in samples were based upon specific gravity tests made on samples cut from the steel bars from which the sheets were rolled. The average specific gravity of several samples was 7·847, which gives 3·91 cubic inches per pound for 90 per cent. solid material. The weight of the sample, on the basis of these calculations, should therefore be 32·13lb. About 20 sample rings were built up and each sample was wound with 72 turns of No. 18 B. & S. annunciator wire, wound in 12 groups of one layer, and six turns each, with the groups symmetrically disposed around the circumference of the ring. The iron loss in each sample was measured at each of the three inductions mentioned above—viz.:

| | C.G.S lines per sq. inch. | | C.G.S. lines per sq. cm. |
|---|---|---|---|
| (*a*) | 65,500 | = | 10,155 |
| (*b*) | 91,100 | = | 14,124 |
| (*c*) | 76,500 | = | 11,860 |

The voltages required for each of the three inductions at 3,000 alternations were obtained from the following calculations:

B = maximum induction per square centimetre;
E = effective volts;
$n$ = periods per second;
$t$ = number of turns;
$a$ = sectional area in square centimetre;

$$E = \pi \sqrt{2}\, a\, n\, t\, B\, 10^{-8}.$$



Short-Circuit Characteristic of a 5,000-kw. 11,000-volt Manhattan Alternator.

Reducing this formula to area in square inches and alternations per minute, we have

$$E = \cdot 2388\, a'\, n'\, t\, B\, 10^{-8},$$

where $a'$ = sectional area in square inches = 4;
$n'$ = alternations per minute = 3,000.

The voltage at the various inductions is then as follows:

(*a*) $E = \cdot 2388 \times 4 \times 3{,}000 \times 72 \times 10{,}155 \times 10^{-8} = 20\ 96.$
(*b*) $E = \cdot 2388 \times 4 \times 3{,}000 \times 72 \times 14{,}124 \times 10^{-8} = 29\ 15.$
(*c*) $E = \cdot 2388 \times 4 \times 3{,}000 \times 72 \times 11{,}860 \times 10^{-8} = 24\cdot 48.$

The losses in the samples were measured by carefully calibrated instruments, and the alternator used for supplying current for the purposes of the test gave a wave of almost exactly sine form. The average results of measurements on the 20 samples were as follows:

(*a*) 0·1340 watts loss per cubic inch.
(*b*) 0 2320 watts loss per cubic inch.
(*c*) 0·1724 watts loss per cubic inch.

The total watt loss in the armature was, therefore, as follows:

(*a*) 234,000 × 0·1340 = 31,830 watts.
(*b*) 16,500 × 0·2320 = 3,821 ,,
(*c*) 20,300 × 0·1724 = 3,492 ,,

Total ..... 38,693 watts.

The impracticability of making an accurate determination of the iron losses after the machine had been assembled is to be regretted, as the method adopted and just described contains probabilities of error which cannot be predetermined or eliminated. The armature casting is made in six sections, and the sheet-steel laminations are each no greater than 6ft. in length, thus making in the magnetic circuit six butt and numerous lap joints. The losses due to these breaks in the magnetic circuit are, of course, neglected when the determination of the iron losses is made in the manner just described, but it is probable that they are of so small a value when compared with the total losses as to be negligible.

*Resistance Measurements of Armature and Field.*—These measurements were made by the usual drop-of-potential method, the temperature of the winding and of the room being observed. The resistances as measured were then calculated for a room temperature of 25deg. C., and the $I^2R$ losses calculated on this basis. Resistance of armature:

Phase 1—2 R = 0·2325 ohms at 25deg. C.
,, 2—3 R = 0·2332 ,, ,,
,, 1—3 R = 0·2329 ,, ,,

Two times combined resistance of three phases

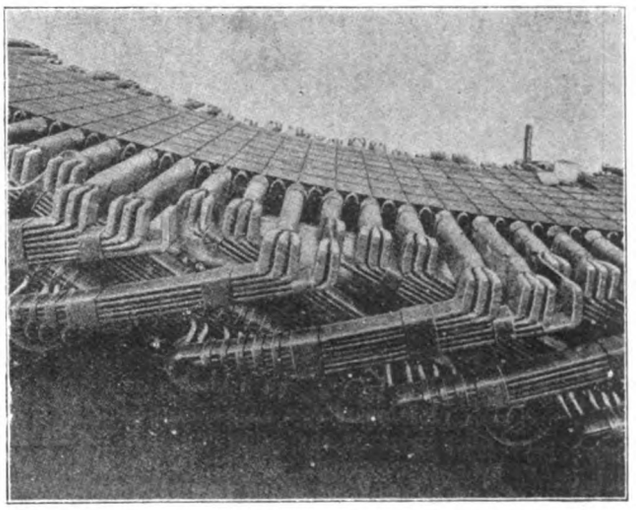
$$= 0{\cdot}2325 + 0{\cdot}2332 + 0{\cdot}2329 = 0{\cdot}6986.$$

Total armature resistance, therefore, equals

$$\frac{0\ 6986}{2} = 0{\cdot}3493 \text{ ohms.}$$

Resistance of field at 25deg. C. = 0·8206 ohms.

*Efficiency.*—As noted above, the efficiency is based on the armature iron losses and the field and armature $I^2R$ losses. The iron losses were determined as described above, and from the resistance values as obtained by measurement the



End Connections of the Armature Winding.

$I^2R$ losses in field and armature have been calculated for various loads from 25 per cent. to 125 per cent. of full rated load. These appear in tabulated form below, and following is a curve plotted from the calculated efficiencies. In calculating the field $I^2R$ loss, 208 1 amperes were used as full-load field current, this value being obtained in the following manner:

| | | |
|---|---|---|
| Field current corresponding to terminal voltage on open circuit plus armature resistance drop = ..... | 198·5 amps. | |
| Field current necessary to give full-load armature current or short-circuit = ..... | 62·6 | ,, |
| Full-load field current is the vector sum of above, or ... | 208·1 | ,, |

| — | ¼ load. | ½ load. | ¾ load. | Full load. | 1¼ load. |
|---|---|---|---|---|---|
| Iron loss.....KW. | 39·69 | 38 69 | 38·69 | 38·69 | 38·69 |
| Armature $I^2R$ loss ,, | 1·51 | 6 04 | 13 59 | 24·16 | 37·75 |
| Field $I^2R$ loss ... ,, | 35·54 | 35·54 | 35·54 | 35·54 | 35·54 |
| Total losses ..... ,, | 76·74 | 80·27 | 87 82 | 98·39 | 111·98 |
| Output ..... ,, | 1,250· | 2,500· | 3.750· | 5,000· | 6,250· |
| Input ..... ,, | 1 325·74 | 2,580 27 | 3,837·82 | 5,098·39 | 6,361·98 |
| Efficiency.....per cent. | 94·29 | 96·50 | 97·71 | 98·06 | 98·24 |

*No-Load Saturation.*—The no-load saturation curve was obtained in the following manner: The alternator field was excited from a 250-volt steam-driven generator running at constant speed. The alternator, with its armature circuit open, was brought to full speed with the engine on the throttle, and held at this speed while the

Digitized by Google

measurements were made. Simultaneous readings of volts field, amperes field, volts armature, and speed were taken. The instantaneous readings of speed were made by means of a frequency indicator which had been previously carefully calibrated. Below is given in tabulated form the instrument readings from which the saturation curve has been plotted. As some of the readings were taken at a frequency higher than 25 cycles (due to the engine speeding up), the armature volts at these points were corrected for this difference in speed by decreasing them in proportion to the increase in speed.

| Frequency. | Amperes field. | Volts field. | Volts armature— Observed. | Volts armature— Corrected. |
|---|---|---|---|---|
| 25·0 | 17·5 | 15·3 | 1,000 | 1,000 |
| 25·0 | 33·5 | 29·4 | 1,963 | 1,963 |
| 25·0 | 51·4 | 44·8 | 3,140 | 3 140 |
| 25·0 | 66·0 | 57·3 | 4,010 | 4,010 |
| 25·0 | 86·0 | 74·5 | 5,150 | 5,150 |
| 25 0 | 101·8 | 87·3 | 6,100 | 6,100 |
| 25·2 | 121·8 | 103·5 | 7,190 | 7,133 |
| 25·2 | 139·0 | 117·8 | 8,120 | 8 055 |
| 25·2 | 157·2 | 134 8 | 9,150 | 9,077 |
| 25·2 | 176·2 | 150·0 | 10,100 | 10,019 |
| 25·2 | 198·0 | 168·5 | 11,160 | 11,070 |
| 25·5 | 214·0 | 183·0 | 11,970 | 11,640 |
| 25·2 | 249·2 | 218·0 | 13,020 | 12,916 |

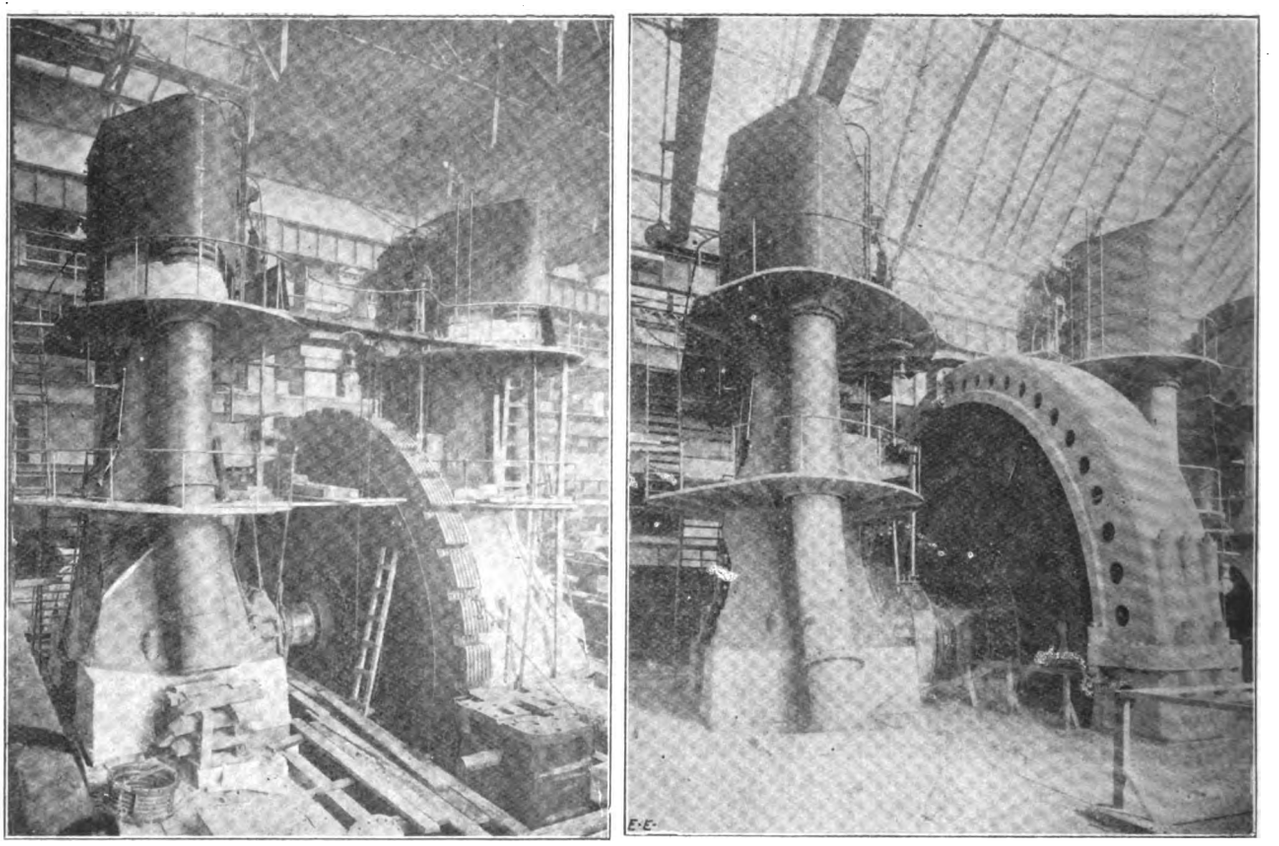
*Short-Circuit Characteristic.*—For this test the armature terminals were short-circuited, the alternator run at full speed and the armature current measured at different values of field current. The tabulated readings and the curve plotted from them are given below:

| Speed R.P.M. | Field amperes. | Field volts. | Armature amperes. |
|---|---|---|---|
| 75 | 50·0 | 36·0 | 210·0 |
| 75 | 68 0 | 50·0 | 300 0 |
| 75 | 100 0 | 74·5 | 411·6 |
| 75 | 120·2 | 89·5 | 516·0 |
| 75 | 141·2 | 105·5 | 588·0 |
| 75 | 181·0 | 140·5 | 744·0 |
| 75 | 193·3 | 158·0 | 798·0 |

*Insulation Test.*—The contract specifications required that after the machine had been assembled, the insulation of the field winding from the frame should be subjected to a puncture test of 2,500 volts alternating E.M.F. for a period of one minute, and that the insulation of the armature winding from the frame should be tested at a potential of 25,000 volts for 30 minutes. As the armature coils had been exposed to moisture for some time before being assembled, it was thought advisable to give them a drying out before subjecting them to the puncture test. For this purpose the armature was short-circuited and the machine run at about two-thirds full speed, with sufficient field current to give about 500 amperes in the armature. This heat run was kept on for about 60 hours, then the machine was shut down and the windings carefully wiped off and allowed to cool to the temperature of the room before the insulation test was made. The insulation tests were made by using a 250-kw., 40,000 : 360-volt 25-cycle oil-cooled transformer, the low-tension winding of which was connected in series with a water rheostat, to the 400-volt 25-cycle station 'bus bars. The potential on the high-tension side of the transformer was measured with a 50,000-volt electrostatic voltmeter which had been previously calibrated. It may be of interest to note that when the test potential was first raised to 25,000 volts, and for some minutes thereafter, a considerable static discharge was noticed taking place over the surface of the windings. As the test was prolonged, this static gradually decreased in intensity until after the lapse of about 20 minutes it almost entirely disappeared.

*Regulation.*—The specifications for this machine provide that "a load of 263 amperes per terminal at 11,000 volts E.M.F. and at 100 per cent. power factor may be thrown off, and the E.M.F. will rise 6 per cent. with constant speed and constant excitation." It has not been found convenient to make an actual measurement of the regulation of the machine, but from the data and characteristic curves it has been calculated. This calculation was made by the usual magnetomotive-force method and the regulation was found to be 4 5 per cent. This figure is undoubtedly too small, as this method of calculation invariably gives results more favourable to the machine than those obtained from actual test.

*Temperature Measurements.*—A number of determinations of the temperature rise in field and armature conductors and in armature laminations were made after the machine had been running under load for a sufficient length of time to have reached a constant temperature. The following



A 5,000-kw. Unit of the Interborough Rapid Transit Company, New York, during construction and as it now appears.

Digitized by Google

results represent the average rise in temperature above the surrounding air of the various parts of the machine after a run of 17 hours at an average load of 5,000 kw.:

| Temperature rise above air: | |
|---|---|
| Field winding | 22·5deg. C. |
| Armature winding | 22·6deg. C. |
| Armature laminations | 25·5deg. C. |

The performance of the eight alternators, of which this one is representative, has been so excellent and the temperature so greatly below the guarantee, that their rating has been increased from 5,000 kw. to 6,000 kw.

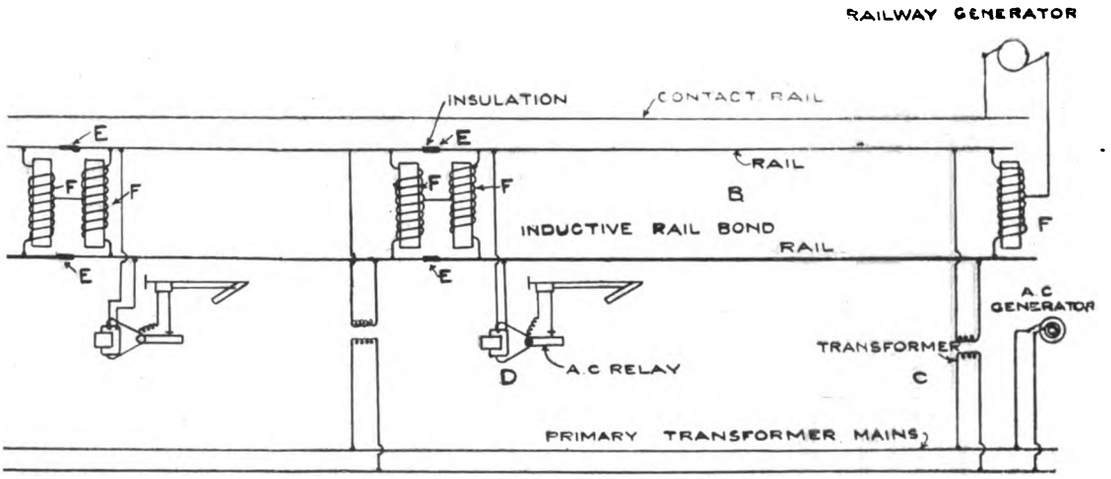


FIG. 1.—Diagram of Connections of the Thullen Alternate-Current Signalling System.

*Testing Synchronising Connections* —After the first machine had been installed it became necessary to make sure of the correctness of the synchronising connections of each of the others as it became ready for operation. For synchronising, dark lamps and a dial synchroniser are used. To make an absolutely certain test of the synchronising connections, the following interesting method was adopted: When the second machine was ready for service, the main switches of both Nos. 1 and 2 were closed, tying the machines to the 'bus. Full-load field current was put on each alternator, and both engines were started simultaneously and slowly brought to full speed together. If the lamps remained dark, and the synchroniser indicated exact synchronism, no better check could be had on all connections. Had there been any wrong connections in the armature circuit of one machine, making a short-circuit when the two machines were tied together, this would have been indicated on the ammeter in the armature circuit immediately after the machines started. The relay would also have operated immediately to open the armature switch. After the two machines had been brought to full speed (tied together), they were then cut apart and synchronised in the usual manner. This method was used with great success on all the machines, a separate 'bus bar being used for the purpose.

## THE THULLEN ELECTRIC SIGNALLING SYSTEM.

In certain electric signalling systems on steam roads it is customary to make one rail continuous, and divide the remaining one by means of insulated joints into sections suitable for signalling. This manner of signalling has been modified to suit electric roads by using a polarised relay, so constructed that the difference of potential at the end of the block, due to the propulsion current, will not operate the relay. In the case mentioned but one rail can be utilised for the return of the propulsion current, the other being used for signalling purposes only. The loss of this rail for a return conductor is supplied by a copper cable, which costs, approximately, £600 to £1,000 per mile, according to the mode of construction. This copper cable adds greatly to the cost of signalling, and the expensiveness of this scheme led Mr. L. H. Thullen to invent a system whereby both rails can be used for the return current, and at the same time the track be divided into sections for signalling purposes. This latter system involves the use of an alternating current for the signalling system, and a relay that is operative by alternating current only.

The idea is shown in diagrammatical form in Fig. 1, in which A and B are block sections of an electrical road; C is a transformer supplying alternating current for the track signalling circuit; D is a relay, operative by alternating current only; E, E are insulating joints dividing the track into sections; F, F are inductive rail bonds that allow the free passage of the propulsion current, and at the same time restrict the alternating current to each individual block section.

The inductive rail bonds, as shown by Figs. 6 and 7, are composed of laminated iron cores wound with a few turns of copper conductor; this conductor is made in sections equal per foot to the carrying capacity of the rail. The length of the winding on these cores is but a few feet, and therefore imposes practically no resistance in the return circuit. In actual practice the resistance imposed in a block

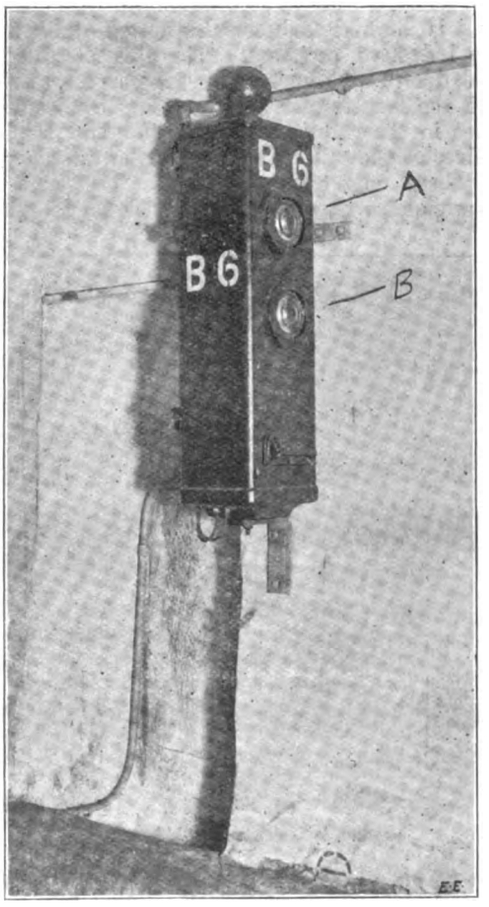

FIG. 2.—A Signal showing the Two Lights.

section 3,000ft. long is less than 1 per cent. As can be seen, the propulsion current traverses one-half of the winding of the bond in one direction and the other half in the other direction, thus neutralising the magnetic action on the core; while at the same time the alternating track current

Digitized by Google

traverses the winding in one direction only, thus making the bond inductive to the alternating track current.

Poor bonding sometimes causes a difference in the amount of current traversing the two rails, and to prevent this the iron core is made with an air-gap in the magnetic circuit. This increases the reluctance of the magnetic circuit, and keeps the core from becoming saturated by the direct

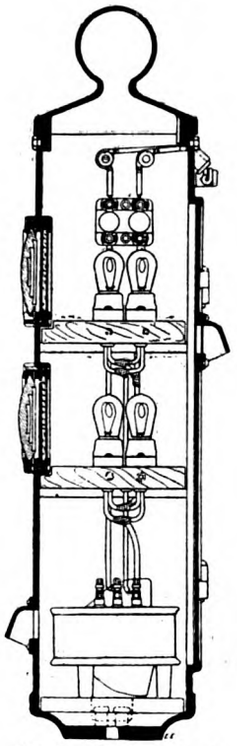

FIG. 3.—Section of Signal.

current. If allowed to become saturated, the bond would lose its inductive property. There is no difference of potential, due to the direct propulsion current, at the point at which the transformer and relay are connected, as the resistance in the coil is extremely low and the same in both halves of the coil. This has the advantage over any system where only one continuous rail is used for the return propulsion current, and the other rail subdivided,

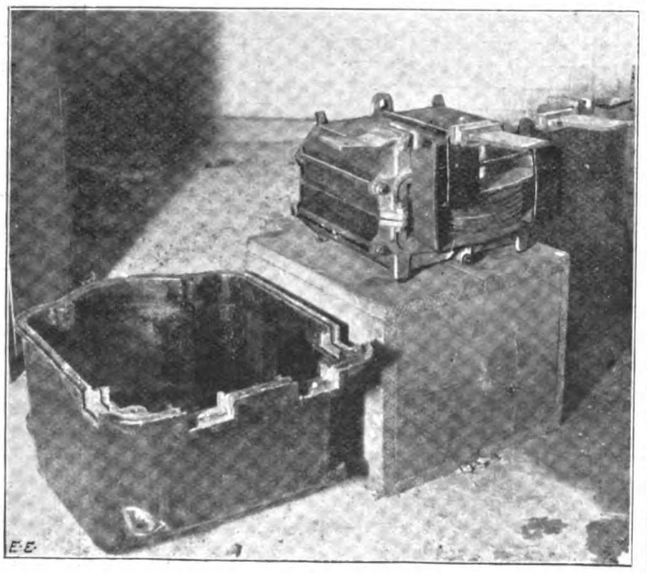

FIG. 6.—An Inductive Rail Bond.

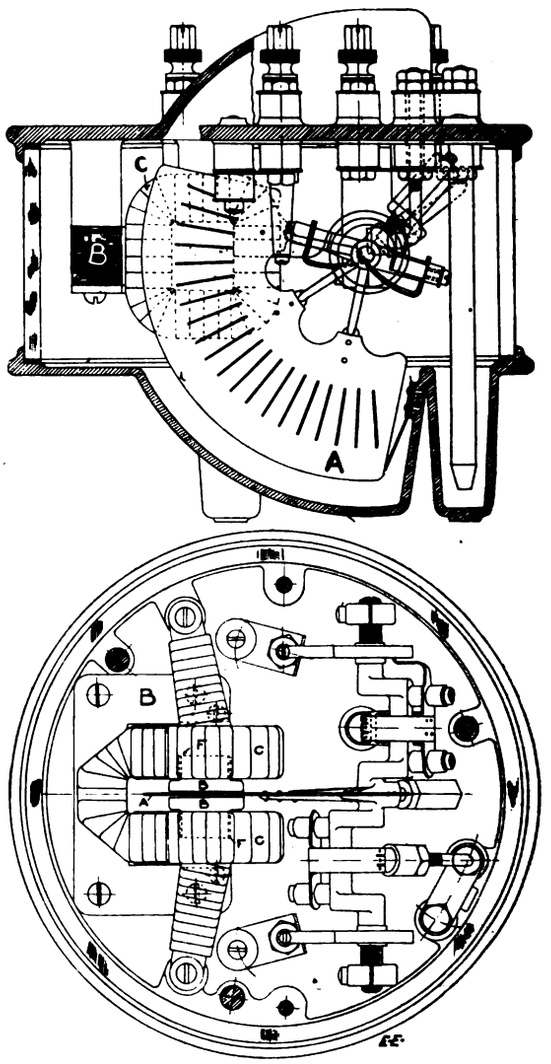
as in the latter case the difference of potential at the ends of the block might be as high as 20 or 30 volts.

This system has been in successful operation in the East Boston Tunnel since Feb. 2, 1905. In that installation alternating current is supplied by primary wires extending the length of the tunnel. Current is furnished to the primaries of the transformers at a frequency of 60 cycles, and a potential of 500 volts. The transformers are wound with two secondary windings; one winding furnishes current at 50 volts to light the signals, the other furnishes current to the track at three volts. The energy taken for one block section, exclusive of the lamps in the signals, is about 75 watts. The signals are lighted with four 4 c.p. lamps, two lamps being connected in multiple back of each lens. Clear glass is used for the lamps, but the lenses are red and green, red being the danger signal and green the clear signal.

The signals used are shown in Figs. 2 and 3. A is a red lens, B a green one. The lamps are lighted and extinguished back of the different lenses by means of the track relay. The relay is shown in Figs. 4 and 5. A is an aluminium vane, B a laminated iron core, and C, C are two coils connected by wires to the rails. A copper furrel, F, embraces one half of the poles B, B. The relay operates on the well-known principle of the generation of eddy currents in the aluminium vane. The eddy current induced in the aluminium vane between that part of the poles



FIGS. 4 AND 5.—Alternate-Current Relay.

embraced by the copper furrel is not in phase with that induced in the other part of the field. We then virtually have a two-phase motor of which the aluminium vane is the armature. Two lamps are connected in multiple, so that if one should burn out the other would still be in service. As low-voltage and low efficient lamps are used one lamp is seldom out, and the possibility of two being out at one time is quite remote. However, no danger would result from both lights being out, as no light is always considered a danger signal. A local relay would be used whereby only one lamp would be in service at a time, the other going into service on the burning out of the first lamp; but the present method has been found to answer nicely, and is void of all complications. The two lamps are placed as close together as possible, one back of the other, and the focussing point of the lens is midway between them. Good results are shown by this method, as

Digitized by Google

there is little difference between the light shown with lamps placed in this position and that shown when the lamps are in the focus of the lens. This method of lighting signals has proved very satisfactory in the New York Subway.

Electrically lighted signals are coming more and more into vogue in the United States. They are now in use on the East Boston Tunnel, the New York Subway, the North Shore Railroad in California, and will be used on the electrified portion of the Long Island Railroad. The part of the Long Island Railroad which will be equipped with these signals is 16 miles in length, and is partly subway, partly elevated, and partly surface road. The installation for this road is well under way, and will be completed some time the coming summer. The overlap system will be used. The blocks will be an average length of 2,000ft., and there will be a home and distant signal for each block. Signals in the subway portion will be similar to those used in the East Boston Tunnel, with the addition of a distant signal, which will be operated by the current of the home signal in the block in advance. The signals for the elevated and surface portions will be of the two-arm semaphore type, operated by electric motors. Current at a potential

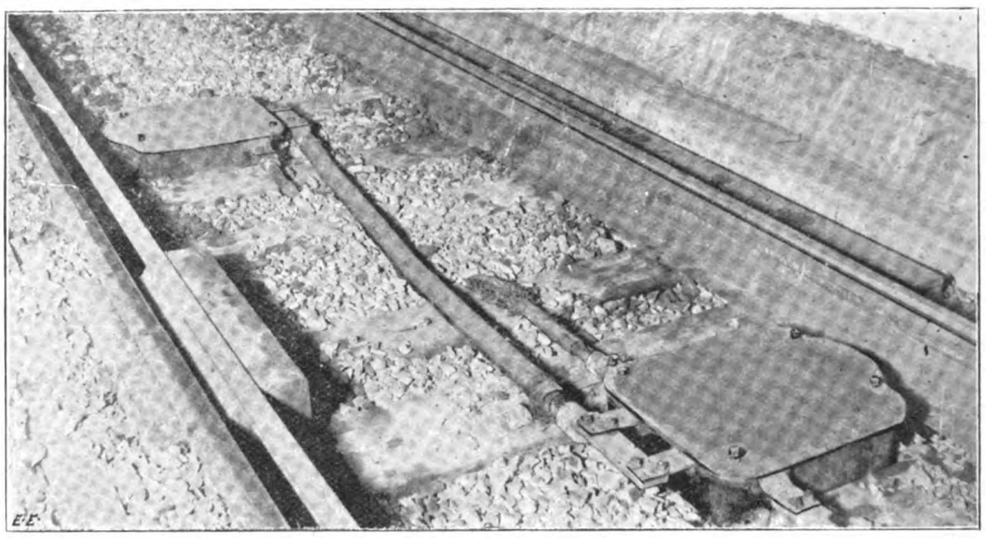


FIG. 7.—View of Track, showing two Inductive Rail Bonds in position.

of 2,000 volts will be furnished the primary of the track transformer by mains extending the entire length of the track.

## THE ALTERNATING-CURRENT SERIES MOTOR.*

BY F. CREEDY, STUDENT.

(*Continued from page 675.*)

### APPENDIX I.

*Symbolic Theory of the Series Motor.*

The theory of the series motor is so simple that it can be treated by a geometrical method, as has been done above, without undue complication. In order, however, to bring out the analogy between the series motor and other motors whose theory is more complicated, and in order to deduce some results which do not come out easily by the geometrical method, I give in this appendix a discussion of the theory of the series motor by Mr. Steinmetz's symbolic method, the only method that can profitably be used when the theory of a motor presents any degree of complexity.

Mr. Steinmetz's methods are now very well known, so that I need not describe them. The idea of the "scalar part" of the product of two vectors, or their "scalar product," is also, I think, perfectly familiar. Thus all that is necessary is to show how this idea may conveniently be introduced into Mr. Steinmetz's method. In the following discussion vectors will be denoted by thick black type, such as $\mathbf{i}$; quantities such as impedances by small capitals, such as $z$; and numbers by italics, such as $n$.

Every vector $\mathbf{a}$ may be written $\mathbf{a} = a(\cos\alpha + j\sin\alpha)$, which may be abbreviated to $a \operatorname{cis}\alpha$. Here $\alpha$ is the angle between $\mathbf{a}$ and the real axis. By a well-known trigonometrical theorem, $\cos\alpha + j\sin\alpha = \epsilon^{j\alpha}$. Therefore, $\operatorname{cis}\alpha = \epsilon^{j\alpha}$.

Consequently, by the laws of exponentials, $\operatorname{cis}\alpha \operatorname{cis}\beta = \operatorname{cis}(\alpha+\beta)$; $\operatorname{cis}\alpha/\operatorname{cis}\beta = \operatorname{cis}\alpha \operatorname{cis}(-\beta) = \operatorname{cis}(\alpha-\beta)$.

Thus the operator $\operatorname{cis}\theta$ simply turns a vector through the angle $\theta$, counter-clockwise or clockwise, according as $\theta$ is positive or negative.

Now the scalar product, or the scalar part of the product, of two vectors $\mathbf{a}$ and $\mathbf{b}$, is the product of the length of either vector into the projection of the other upon it—*i.e.*, it is $a\,b\cos\theta$, where $\theta$ is the angle between $\mathbf{a}$ and $\mathbf{b}$. Thus what we require is a simple and convenient expression for $a\,b\cos\theta$ in terms of $\mathbf{a}$ and $\mathbf{b}$.

If the vector $\mathbf{b}$ lies along the real axis—*i.e.*, if $\mathbf{b} = b$—we have $\mathbf{a}\,\mathbf{b} = a\,b\,(\cos\alpha + j\sin\alpha)$.

Now in this case $\alpha$ is the angle between the two vectors—*i.e.*, $\alpha = \theta$, so that $[\mathbf{a}\,\mathbf{b}]_1 = a\,b\cos\theta$, the expression we require if, following Steinmetz, we denote the real part of a vector, or product of vectors, by square brackets with the suffix $_1$. This is not true unless either $\mathbf{b}$ or $\mathbf{a}$ lie along the real axis.

Now the expression we require only depends on the length of the two vectors, and the angle between them, and not at all on their position with respect to the real axis.

Let $\mathbf{a} = a \operatorname{cis}\alpha$ and $\mathbf{b} = b \operatorname{cis}\beta$. Let us multiply both these vectors by $\operatorname{cis}-\beta$, thus turning them till $\mathbf{b}$ lies along the real axis. If we call the vectors so turned $\mathbf{a}'$ and $\mathbf{b}'$, then $\mathbf{a}' = a \operatorname{cis}\alpha \operatorname{cis}-\beta$ and $\mathbf{b}' = b$.

Then $\mathbf{a}'\,\mathbf{b}' = a\,b \operatorname{cis}\alpha \operatorname{cis}-\beta = a \operatorname{cis}\alpha\, b \operatorname{cis}-\beta$, and the real part of this, as shown above, is the expression we want.

Now $b \operatorname{cis}-\beta$ is the conjugate of $\mathbf{b}$.

Thus $\mathbf{a}'\,\mathbf{b}' = \mathbf{a}\,\bar{\mathbf{b}}$, where $\bar{\mathbf{b}}$ denotes the conjugate of $\mathbf{b}$ and $[\mathbf{a}'\,\mathbf{b}']_1 = [\mathbf{a}\,\bar{\mathbf{b}}]_1 = a\,(b\cos(\alpha-\beta)) = b\,(a\cos(\beta-\alpha)) = [\bar{\mathbf{a}}\,\mathbf{b}]_1$

Thus we have arrived at the conclusion that the product of the length of either vector into the projection of the other upon it, is

$$[\mathbf{a}\,\bar{\mathbf{b}}]_1 = [\bar{\mathbf{a}}\,\mathbf{b}]_1$$

Similarly, it might be proved that

$$[\mathbf{a}\,\bar{\mathbf{b}}]_j = -[\bar{\mathbf{a}}\,\mathbf{b}]_j$$

is the "vector part" of the product of $\mathbf{a}$ and $\mathbf{b}$, where the square brackets with the suffix $j$ denote that the imaginary part only of $\mathbf{a}\,\bar{\mathbf{b}}$ is taken. As I shall have no occasion to use this, however, I need not go into it here. By the introduction of this "scalar part," Mr. Steinmetz's method becomes a system of analytical geometry of great power, as will be found by those who use it. Let us apply this method to the series motor.

Let $\mathbf{e}_0$ be the impressed E.M.F.

$\mathbf{i}$ „ current.

$z_0$ „ impedance due to the main flux and iron losses.

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

Let $z_1$ be the impedance due to the resistance and leakage.
$z_2$ ,, armature impedance.

In this motor the following E.M.F.'s occur:

(1) $e_0$ the impressed E.M.F.
(2) $e_1$ the counter E.M.F.
(3) $e$ the E.M.F. induced in the field by the main flux.
(4) $-i z_1$ the E.M.F. due to the resistance and leakage of the field.
(5) $-i z_2$ the E.M.F. due to the impedance of the armature.

Now $e$ may be expressed in the form $-i z_0$, and will lag 90deg. behind the flux, and consequently more than 90deg. behind the current. Moreover, $e = 2\pi f i n^2 p\, 10^{-8}$, where these symbols have the same meanings as in the paper.

Now $e_1$ lags 90deg. behind $e$, and has the magnitude $4 s i n n_1 p\, 10^{-8}$.

Thus
$$e_1 = \frac{s}{2\pi f}\,\frac{4 n_1}{n}\, j e.$$

Let us put $\frac{4}{2\pi}\,\frac{n_1}{n} = a$ and $\frac{s}{f} = k$.

Then
$$e_1 = -i a j k z_0.$$

Now, by Kirchhoff's law the sum of the above E.M.F.'s must be zero.

$$\therefore\ e_0 - i(z_0 + z_1 + z_2) - i a j k z_0 = 0 \quad . \quad . \quad (1)$$

the fundamental equation of the series motor. Let us multiply through by $-\bar{i}\,\bar{z}$, and take the real part only of the product. We get

$$[\bar{i}\,\bar{z}_0\,(i(z_0 + z_1 + z_2) - e_0)]_1 = 0$$

(since $i z_0\ \bar{i}\,\bar{z}_0$ is real, the term involving $k$ is purely imaginary), and $k$ is eliminated.

Multiplying out and dividing by $[\bar{z}_0\,(z_0 + z_1 + z_2)]_1$,

$$i^2 - \left[ i e_0 \frac{\bar{z}_0}{[z_0\,(z_0 + z + z_1)]_1} \right]_1 = 0,$$

since $i\,\bar{i} = i^2$ a scalar. Writing

$$2c = e_0 \frac{\bar{z}_0}{[z_0\,(z_0 + z_1 + z_2)]_1},$$

and factorising again

$$[\bar{i}\,(i - 2c)]_1 = 0, \text{ or } i^2 = 2[\bar{i}\,c]_1 \quad . \quad . \quad . \quad (2)$$

The first equation asserts that $i - 2c$ is perpendicular to $i$, and is therefore the equation of a circle passing through the origin.

Dividing equation (1) by $(z_0 + z_1 + z_2)$ and transposing, we get

$$\frac{e_0}{z_0 + z_1 + z_2} - i = i\,\frac{a j k z_0}{z_0 + z_1 + z_2}.$$

Setting $\frac{e_0}{z_0 + z_1 + z_2} = i_s$, changing the sign, and dividing by $i$

$$\frac{i - i_s}{i} = -\frac{a j k z_0}{z_0 + z_1 + z_2} \quad . \quad . \quad . \quad . \quad (3)$$

Now $i_s$, the standstill current, is equal to OS in Fig. 2, and $i$ to OI. Thus equation (3) asserts that $\frac{SI}{OI}$ is proportional to the speed. In fact, the process by which equation (3) was derived from equation (1) suggested the geometrical proof of the circle-diagram, which I gave above. Now torque × speed = output, or

$$\text{Torque} = \frac{\text{output}}{\text{speed}}, \text{ or is proportional to } \frac{I}{k}[\bar{i}\,e_1]_1.$$

Thus since $e_1 = -i a j k z_0$

$$\text{Torque} = i^2 [a j z_0]_1.$$

Now from equation (2)

$$i^2 = [\bar{i} \,.\, 2c]_1 \text{ or } OI^2 = OM \,.\, ON \text{ (Fig. 2)},$$

substituting

$$\text{Torque} = [\bar{i} \,.\, 2c]_1\,[a j z_0]_1 \quad . \quad . \quad . \quad (4)$$

Thus the torque is proportional to the projection of the current vector on 2c—*i.e.*, on that diameter of the circle which passes through the origin.

*The Lines of Constant Output.*

Equation (1) may be written

$$e_0 - i(z_0 + z_1 + z_2) = e_1.$$

Now output $= [\bar{i}\,e_1]_1$. Let us substitute the value of $e_1$. We get

$$[\bar{i}\,(e_0 - i(z_0 + z_1 + z_2))]_1 = [\bar{i}\,e_1]_1 = c$$

if we put output $= c$. This is the equation of a circle, as will be shown below.

Multiplying out, changing the sign, and dividing through by $[z_0 + z_1 + z_2]_1 = r$, the total resistance of the motor, we get

$$i^2 - 2\left[ \bar{i}\,\frac{e_0}{2r} \right]_1 = -\frac{c}{r}.$$

Adding to both sides $\left|\frac{e_0}{2r}\right|^2$ we get

$$i^2 - 2\left[ \bar{i}\,\frac{e_0}{2r} \right]_1 + \left|\frac{e_0}{2r}\right|^2 = \left|\frac{e_0}{2r}\right|^2 - \frac{c}{r}.$$

Factorising again, we get

$$\left| i - \frac{e_0}{2r} \right|^2 = \frac{e_0^2}{4r^2} - \frac{c}{r} \quad . \quad . \quad . \quad . \quad (5)$$

The two vertical lines in the above equations form the usual notation for the modulus or absolute magnitude of a complex quantity. The use of an italic letter, though very convenient to denote the magnitude of a single symbol, is obviously inapplicable to a sum of complex quantities such as occurs above.

So long as $r$, the total resistance of the motor, remains constant, it is obvious that the above equation represents a circle, the vector to the centre being $\frac{e_0}{2r}$, and the radius $\sqrt{\frac{e_0^2}{4r^2} - \frac{c}{r}}$. Thus when the output is zero the circle passes through the origin. Now it is obvious that the output can only be zero when the speed is zero. Thus we see that the *locus* of the standstill current vector, as we vary either the field turns or the armature turns, or both, is a circle passing through the origin, and having its centre on the line along which the impressed E.M.F. is set out. That the lines of constant output, in practice, are circles, is shown fairly well by Fig. 6, above.

A construction for the radius of the circles of constant output is easily found. Let us describe a semicircle on $\frac{e_0}{2r}$. If an output circle cuts this at the point C (Fig. 15), then $R^2 = \frac{e_0^2}{4r^2} - O C^2$.

Hence $O C^2 = \frac{c}{r}$. This gives us the construction we require.

*The Lines of Constant Efficiency.*

We have
$$\text{Efficiency} = \frac{\text{output}}{\text{input}} = \frac{[\bar{i}\,e_1]_1}{[\bar{i}\,e_0]_1} = \eta$$

if we put efficiency $= \eta$, a constant. Substituting for $e_1$ from the equation—

$$e_1 = e_0 - i(z_0 + z_1 + z_2),$$

as was done above, we get

$$[\bar{i}\,(e_0 - i(z_0 + z_1 + z_2))]_1 = \eta\,(\bar{i}\,e_0]_1,$$

or,
$$[\bar{i}\,(e_0(1 - \eta) - i(z_0 + z_1 + z_2))]_1 = 0,$$

the equation of a circle passing through the origin.

Multiplying out, dividing by $[z_0 + z_1 + z_2]_1 = r$, the total resistance of the motor, and changing the sign, we get

$$\left[ \bar{i}\,\left( i - \frac{e_0(1 - \eta)}{r} \right) \right]_1 = 0.$$

Thus the diameter of the circle, $\frac{e_0(1 - \eta)}{r}$, gets smaller as the efficiency gets higher. The circle of zero efficiency is identical with the standstill current circle, as one would expect, while the circle of 100 per cent. efficiency is a mere point (the origin). These circles are shown in Fig. 15. They give us yet another linear construction for the efficiency, though not a very convenient one. Draw a perpendicular from the extremity of any standstill current vector cutting the line of unity power factor at a certain point, P. From the extremity of any other current vector

Digitized by Google

draw a line perpendicular to it, cutting the line of unity power factor in Q. Then P Q measures the efficiency corresponding to that current vector.

*Effect of Varying the Number of Field Turns.*

In order to consider the effect of varying the number of turns on the field, it is necessary to express the constants of the motor in terms of the number of field and armature turns.

The total reactance of the field is

$$-j\,2\,\pi\,f\,n^2\,p\,\nu\,10^{-8} = -j\,n^2\,x_0.$$

The total reactance of the armature is

$$-j\,2\,\pi\,f\,n_1^2\left(\frac{2}{\pi}\right)^2 p_1\,10^{-8} = -j\,n_1^2\,x_2.$$

The counter E.M.F. is equal to

$$4\,i\,s\,n\,n_1\,p\,10^{-},$$

and differs in phase from the current by a small angle.

Thus it may be represented by $-\mathrm{i}\,k\,n\,n_1\,\mathrm{Z}$, where

$$\mathrm{Z} = \frac{a\,j\,\mathrm{Z}_0}{n\,n_1}.$$

The resistances of the field and armature are proportional to the number of turns on each if we use the same size wire throughout. The "equivalent resistance" of the field, due to the iron losses, is also proportional to the number of field turns. There will also be a resistance which may be assumed constant, due to the brushes, etc. Thus the resistance of the motor may be expressed in the form $r_0 + n\,r + n_1\,r_1$. However, as the influence of the resistance on the shape of the curves is small, I shall consider the resistance of the motor as a constant, $r$. The fundamental equation of the series motor now takes the form,

$$\mathrm{e}_0 - \mathrm{i}\,(r - j\,(n^2\,x_0 + n_1^2\,x_2) + k\,n\,n_1\,\mathrm{Z}) = 0 \quad . \quad (6)$$

The first thing that we notice about this equation is that it is of exactly the same form both in $n$ and in $n_1$. Consequently any curves which we may arrive at by considering $n_1$ as constant and $n$ as variable will be paralleled by exactly similar curves obtained by considering $n$ as constant and $n_1$ as variable.

*To plot the locus of* i *in equation* (5) *if* $n_1$ *and* $k$ *are constant*

Dividing equation (5) by i, we get

$$\frac{\mathrm{e}_0}{\mathrm{i}} = r - j\,(n^2\,x_0 + n_1^2\,x_2) + k\,n\,n_1\,\mathrm{Z}.$$

Thus $\frac{\mathrm{e}_0}{\mathrm{i}}$ or $\frac{\mathrm{I}}{\mathrm{i}}$ will move on a parabola, as may easily be seen. The simplest way to plot the *locus* of i seems to be to first plot this parabola, the *locus* of $\frac{\mathrm{e}_0}{\mathrm{i}}$. The reciprocals of the vectors to this parabola will to a suitable scale be the vectors to the curve required.

Now, the reciprocal of a compiex number, regarded as a vector, is a vector having a reciprocal length, and making an opposite angle with the real axis to that made by the original vector. We shall evidently obtain the same results if we set out the reciprocals along the line of the original vectors, and then change the direction of rotation of our diagram from clockwise to counter-clookwise, thereby changing an angle $\alpha$ into an angle $-\alpha$, as if we set out the reciprocals, making an opposite angle with the real axis to that made by the original vector. I usually adopt the first procedure as being the most convenient.

Thus with the aid of this parabola it is quite easy to plot the *locus* of i in equation (5) or the curve on which the current vector moves if we keep the speed constant and vary the number of field turns. We obtain a number of points on it corresponding to various values of $n$. To each of these values corresponds a current circle, such as is discussed above. If we neglect the phase difference between current and counter E.M.F. as has been done for convenience in Fig. 15, these circles will all have their centres on the line of zero power factor. Since they all pass through the origin, the point just obtained on each serves to determine it completely.

Having obtained, as above, one line of constant speed, and having also the standstill current circle, it is easy to draw as many other lines of constant speed as may be required by means of the speed construction given in Fig. 2.

In Fig. 15 are shown three of these speed lines. Together with the lines of constant output these lines enable us to determine the torque, output, efficiency, etc., corresponding to any speed and any number of field turns. From the lines of constant speed we see that as we increase the number of field turns the power factor rises to a maximum, and then falls slowly down to zero again. In fact, when $n = \infty$ equation (6) becomes

$$\mathrm{i} = \frac{\mathrm{e}_0}{-\mathrm{j}\,n_2\,x_0},$$

which has a direction perpendicular to $\mathrm{e}_0$. Thus the speed lines are all tangent to the line of zero power factor at the origin. As we saw above in the paper, the power factor attains a maximum for a definite ratio of armature turns to field turns which is independent of the speed. Thus, if the number of armature turns be constant, there will be one current circle in Fig. 15 for which the power factor will be a maximum at every speed.

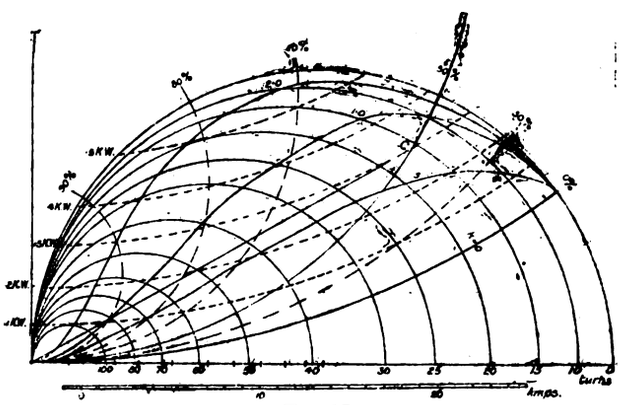

FIG. 15.

In Fig. 11 are given some experimental curves showing the relation between output and number of field turns at constant speed. Although this relation cannot profitably be studied analytically, on account of the complication of the equations involved, Fig. 15 gives us a simple geometrical means of studying it. We see that the point at which the output circle touches a given speed line gives us a smaller value of $n$ the greater the speed, till finally, when

$$k = \infty \quad n = 0,$$

## PERSONAL.

We understand that the Johannesburg appointment has not yet been officially confirmed, therefore to make a definite statement would be somewhat premature.

Mr. Lackie, the chief electrical engineer of the Glasgow Corporation, in the name of the employés, has presented to Mr. W. A. Chamen a pair of silver candlesticks and a silver inkstand as a memento of his occupancy for seven years of the post of chief engineer to the Corporation electricity department; and Mr. R. B. Mitchell, on behalf of the street labourers, has presented to Mr. C. H. K. Chamen a dressing case and pocket knife.

Mr. L. Paton Greig, borough electrical engineer, Bury St. Edmunds, has been appointed engineer to the Richmond (Surrey) Electric Light and Power Company, Limited, in succession to Mr. M. C. Flemyng, resigned.

The Bournemouth Corporation have appointed Mr. Bulfin (electrical engineer) resident engineer in connection with the construction of the Christchurch tramways. On the completion of this line he will act as electrical engineer for the whole of the system, including the Poole lines, at a salary of £400 per annum, rising by annual increments of £25 to £450. The Council have also increased the salary of Mr. Barber, traffic manager, from £300 to £400 per annum, rising by annual increments of £25 to £450 per annum.

The Luton Town Council have increased the salary of the electrical engineer, Mr. Cooke, from £230 to £260 per annum.

**Handbook.**—The revised edition of the official handbook upon Felixstowe and the locality, edited by Mr. Lemmon Lingwood and published by Jarrold and Sons, Limited, should relieve the visitor from any need of invoking the guidance of the local constabulary. It contains a quantity of information about the chief buildings, postal and travelling services, recreations, and the like, in addition to a historical sketch of the town and a number of illustrations.

## ELECTRICITY—DEFENSIVE AND OFFENSIVE.

The report of Mr. Fedden to the Electric Light Committee of Sheffield seems to us to indicate a new departure. The army that acts purely on the defensive is usually in the long run worsted, and the country that ceases to be aggressive ceases to be progressive, so the industry that sits down and takes the attack of vigorous opposition without deigning a reply is in danger of extinction. It seems to us that the electric lighting industry is passing through a very real crisis, and if its supporters are not more aggressively combative, it is likely to experience a hard time. In these days of associations, of books, pamphlets, and technical papers it is rather a hazardous thing to dogmatise in the direction that the electric lighting problem has never yet been properly attacked, hence not yet properly solved. It is not so simple as it looks. Interior lighting has to provide for anything between the extremes of a rushlight and a brilliantly lighted ballroom, hence even for interiors, if one system of lighting is to become universal, it must possess great versatility and not lack economy. It is, however, not so much with interior lighting as with exterior that such reports as this of Mr. Fedden's provide pabulum for thought. Has this problem of street-lighting ever been properly considered? Have we not always had that millstone of comparative cost round our necks, to the great detriment of asking what is wanted? At the same time when arc lighting was introduced the gas lighting of our streets was not lighting at all, so far as the requirements of civilised life were concerned—it was merely the survival of a something better than lanterns. The progress of trade, of civilisation, of the necessities of modern life, has left nothing in common with what existed only a century or so ago. Then the world lived and moved and worked practically only between sunrise and sunset. People did not shop after dark; they mostly dined at midday and went to bed early. Now it is fashionable to dine at eight, and go to the theatre later. When the house doors were locked at nine, the question of lighting the streets resolved itself into the getting of mere guiding lights for belated travellers. At the present time the main streets are used almost or quite as much during the four hours ending at midnight as during the four hours ending at midday, and the nearer the lighting of these streets during the absence of the sun approaches that when it gives light the better, and more economically can trade and traffic be carried on. So far as side streets and residential streets are concerned, the problem is a different one and resolves itself into giving enough light to guide the traveller and to prevent crime. It seems to us, then, that the first factor a lighting authority should consider is quantity, or more scientifically, the intensity of light per unit area in the main streets that will enable trade and traffic to be carried on in the best and most economical way under the existing modern conditions. When they have determined that intensity, then, and not till then, should the cost to provide that intensity by various kinds of illuminants be considered. We have no hesitation in saying that nothing at present known is as cheap as electric energy to give the lighting which ought to be provided in our main thoroughfares. We do not forget—and the electrical engineer ought never to forget—the immense strides made by gas engineers since the introduction of electricity as a luminant. The electrical engineer, partly because of his cock-suredness, has not made so great comparative advance. It seems to us that sometimes he forgets that good lighting depends not only on candle-power, but quite as much, if not more so, upon the

Digitized by Google

equitable diffusion of light. Lighting is not good where here you get brilliance and there shadow. Much of our lighting is like a corduroy road, equally distributed in ridge and furrow, in the case of the lighting alternately light and dark. What is the use of all the talk and discussion about candle-power if half the area supposed to be lighted is really not so? While the law that intensity varies with the square of the distance holds good, the limit of distance between the point of generation of light is practically determined, and intense centres of light at long distances apart should be avoided. The people who from time to time have suggested huge candle-powers on high masts at long distances apart have failed to prove the practicability of the idea, as might have been expected, for the system is wrong in principle. Mr. Fedden is on firmer ground when he considers the existing conditions and compromises so as to give each condition the maximum it can have when the requirements of the other conditions have been similarly satisfied.

## CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

### FORCED DRAUGHT.

SIR,—The article on "Gloucester Electricity Works," by W. J. Bache, in your issue of the 9th inst., giving the cost of forced draught as compared with the chimney stack, sums up greatly in favour of the former. This result is arrived at by means of charging against the motor-driven fan 54,000 units per annum at ¼d. per unit. The previous description of the plant gave no impression of exceptional economy to account for this low charge, and a few pages over the works' costs are given at 1d. per unit, one item alone—coal—accounting for ·35. To me this difference requires an explanation, which may only be a matter of up-to-date book-keeping at present an unknown quantity to—Yours, etc.,

CLYDE.

FRIDAY, JUNE 16.

**Physical Society.** — "The Ratio between the Mean Spherical and Mean Horizontal Candle-power of Incandescent Lamps," by Dr. J. A. Fleming; "The Electrical Conductivity of Flames," by Dr. H. A. Wilson; "Contact with Dielectrics," by Mr. R. Appleyard; "The Pendulum Accelerometer, an Instrument for the Direct Measurement and Recording of Acceleration," by Mr. F. Lanchester; "A New Form of Pyrometer," by Mr. N. V. Stanford; and an exhibition of a refractometer by Mr. R. Appleyard.

MONDAY, JUNE 19.

**Institution of Mechanical Engineers.**—Summer meeting at Liége commences. Particulars in another column.

WEDNESDAY, JUNE 21.

**Royal Meteorological Society.**—At 4.30 p.m., "Normal Electrical Phenomena of the Atmosphere," by Mr. George C. Simpson; and "Two New Meteorological Instruments: (1) Automatic Pole Star Light Recorder, and (2) The Ombroscope," by Mr. S. P. Fergusson.

**Dynamicables.**—Dinner at the Trocadero, June 21.

**King's College.**—Annual dinner at the Hotel Cecil, June 26.

**Electrical Contractors' Association.**—Dinner at the Holborn Restaurant, June 27.

**Incorporated Municipal Electrical Association.**—June 27 30, annual convention.

**City and Guilds of London Institute.**—Exhibition at the Imperial Institute, to be opened on June 28, at 3.30 p.m.

**Municipal and County Club.**—House dinner (W. H. Grenfell, Esq., M.P., principal guest), June 29.

**Institution of Electrical Engineers.**—Conversazione, June 29.

**Junior Institution of Engineers.**—Summer meeting commences June 30. For particulars see another column.

**University of Liverpool.**—Opening of new electrotechnics laboratory by Sir J. Swan, July 8.

**Permanent-Way Institution.** — Summer convention begins on July 21, continuing till July 27, in the course of which a visit will be paid to Holland.

## THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

### Thirteenth Annual Meeting—Dortmund and Essen.

[FROM OUR SPECIAL CORRESPONDENT.]

Appropriately enough, the thirteenth annual meeting of the Verband Deutscher Elektrotechniker held last week in Dortmund and Essen was heralded by a thunderstorm. It is usual for the members and their ladies to meet for social intercourse on the evening prior to the first general business meeting, and I fear this storm may have diminished the attendance. However, it was early apparent that the meeting would be a record one in point of numbers. The news soon circulated that it would not fall far short of 600—nor did it as a matter of fact. This proves the readiness of our Teutonic friends to avail themselves of any exceptional opportunity which may come in their way. On this occasion the chief ambition of all was to inspect Messrs. Krupp's celebrated works, apart from which the programme of visits arranged in the district offered very tempting bait. Neither Dortmund nor Essen in itself could be by any stretch of the imagination styled attractive, but by reason of intimate association with the iron and coal industries of Westphalia and the Rhine Provinces each is of first-rate commercial importance. The industrial portions of Westphalia and the Rhine Provinces together constitute what may be termed the Black Country of Germany. In extent this country is some 80 km. long by 30 km. wide, and is the most thickly populated and busy district on the European Continent, resembling with its numerous mines, ironworks, and miscellaneous factories one continuous hive of industry. Corresponding to the rapid development of its mineral resources the increase in the population of this track of country has been quite phenomenal, necessitating the erection by the local authorities of workmen's dwellings and the establishment of colonies near the works on an extensive scale. The coal mines employ no less than 270,000 workpeople, a further 160,000 or thereabouts being engaged in the iron industry—together, 430,000. The progress which has been made during the past 10 years is attributed largely to the formation and activity of the great coal syndicate, which in 1893 put a stop to unwholesome competition and unremunerative prices, while consolidating the industry and preparing it for steady development. The policy pursued by this syndicate, whose headquarters are in Essen, has been freely discussed, the shutting down of certain pits calling forth especially severe criticism. No doubt, however, over-production was at the root of the original trouble, and the forcible method adopted to prevent this has had the desired effect, reacting favourably in the long run also on the iron industry. It is surely an economically sounder policy to regulate the output to the demand by working less pits than by restricting hours of labour. But apart from economics it is interesting to note the growing tendency in Germany for the coal mines to devolve into the hands of a few very large companies. A similar tendency exists in regard to the electrical industry, and one wonders where combination will cease. As for the stimulus given to the German electrical industry by enterprise in the mining country of Westphalia and the Rhine Provinces, the value of same can be scarcely overestimated. It was here that the first large direct-coupled electrically-driven pump, the first high-pressure centrifugal pump, and the first main winding engines driven by three-phase and continuous current motors were erected. It was here also that the possibility of utilising blast-furnace gas for driving gas-engines was first practically demonstrated.

In welcoming the visitors to Dortmund on Sunday evening, the President of the local section of the V.D.E. said that according to recent statistics about 500,000 h.p. of dynamos had been installed during the last five years in the Black Country of Germany. I quote this statement merely to convey an impression of the extensive use to which electricity is put for industrial purposes within the area in question.

Drs. Wilhelm Siemens and Gisbert Kapp were prominent among the first gathering of members. The prospect of a large attendance and its early realisation were no doubt

Digitized by Google

gratifying to Dr. Kapp. Indeed, the meeting was a personal triumph for our esteemed friend. He has piloted the V.D.E. through troubled waters, and leaves it flourishing as never before. That the members have felt his able generalship during the past 11 years, and are not ungrateful, was apparent on all sides.

Further, I am pleased to report that his services in the cause of the profession of which he is himself so eminent a representative have also been recognised in wider circles, the honorary title "Doctor of Engineering" having been conferred upon him by the Universities of Dresden and Karlsruhe. This, in view of the important appointment which he is so soon to take up at the Birmingham University, is of peculiar interest. Hearty congratulations, Dr. Kapp.

*(To be continued.)*

## AN APPLICATION TO ELECTROLYTES OF THE HYDRATE THEORY OF SOLUTIONS.*

BY DR. T. MARTIN LOWRY.

The object of the paper is to consider the possibility of extending the hydrate theory to electrolytes in such a way as to take account of the observations which form the experimental basis of the theory of electrolytic dissociation. The hydrate theory postulates that an aqueous salt solution consists of a mixture of hydrates in equilibrium with the solvent and with one another. But it must be supposed that even in solution there is a limit to the possibility of hydrate formation, so that ultimately a stage will be reached at which the molecule as such will be unable to combine with any further quantity of water. The ionisation of an aqueous electrolyte consists essentially in a further process of hydration, whereby the fully hydrated molecule combines with an additional quantity of water to form two or more hydrated ions. The hydration of the ions is thus conceived to be the primary cause of the ionisation of aqueous electrolytes. It is believed that this extension of the hydrate theory to the phenomena of electrolysis may help to remove the fundamental difficulty of Arrhenius's theory—namely, the absence of a *motive* for electrolytic dissociation.

The evidence in support of the hydrate theory of ionisation is summarised as follows:

1. The theory is in accord with the fact that the best "ionising" solvents are those which are themselves most highly associated. Whilst Arrhenius laid special stress on dissociation as the characteristic feature of the process of ionisation, the hydrate theory emphasises an association of solvent and solute which is the primary cause of the separation of the ions. Such an association with the solute may be expected to occur most readily in the case of solvents composed of molecules having a high coefficient of association.

2. Complete ionisation is possible only in presence of a very large excess of water—that is, under exactly those conditions which are most favourable to the formation of complex hydrates.

3. The influence of temperature on ionisation is also in accord with the view that the process is essentially one of association with the solvent.

4. Evidence in favour of the hydrate theory of ionisation is afforded by a consideration of the mobilities of the different ions in aqueous solutions. In the following table of ionic mobilities

| Li | Na | K | Rb | Cs |
|---|---|---|---|---|
| 33·44 | 43·55 | 64·67 | 67·6 | 68·2 |

the larger atoms yield the more mobile ions; the lithium ion (at. wt. 7) moves through the solution only half as rapidly as the rubidium ion (at. wt. 85) or the cæsium ion (at. w. 133). Such a result strongly supports the view that in aqueous solutions the ions are present in the form of complex hydrates.

5. The mobility of the hydroxyl ion is more than double as great as that of any other anion; whilst that of the hydrogen ion is nearly five times as great as that of any other kathion. The peculiar properties of these two ions are most readily explained by supposing that they are either anhydrous or are combined with a smaller proportion of water than any of the other ions. Confirmation of this view is afforded by at least two independent considerations:

(1) The affinity of water molecules for the ions H and OH must be relatively slight, since otherwise liquid water, like fused salt or caustic soda, would be a good electrolyte.

(2) Whereas nearly all sodium and potassium salts are good conductors, the acids from which they are derived are often exceedingly poor conductors.

6 Independent evidence in favour of the hydrate theory of ionisation is to be found in a consideration of the freezing points of dilute aqueous solutions. At extreme dilutions the molecular depression of the freezing point reaches a maximum value corresponding very closely with that required by the theory of electrolytic dissociation. In less dilute solutions, however, values are obtained which cannot be accounted for in terms of this theory as originally propounded, but which are explicable if, as the hydrate theory assumes, part of the solvent is removed as far as freezing-point lowering is concerned.

7 The theory of electrolytic dissociation owes much of its acceptability to the readiness with which it lends itself to exact mathematical treatment. The whole theory can, indeed, be summed up in the well-known equation,

$$K = m\alpha\,(u+v).$$

The essential constants of the hydrate theory are, however, quite as simple as those of Arrhenius's theory. For any given solution the chief constants are: (1) The *total hydration*, H, of the solution, which expresses the total number of molecules of water present per molecule of salt. (2) The *coefficient of combination*, $\beta$, which expresses the fraction of the total quantity of water that is actually combined with the salt to form hydrates. (3) The product of these two quantities will give the average composition of the hydrates in solution; this may be termed the "molecular hydration" of the solution, and may be represented by the symbol $h$. Thus $h = \beta H$ may be regarded as the fundamental equation of the hydrate theory. Jones and Getman and Biltz have attempted to determine the molecular hydration of dissolved salts. Assuming that the abnormally great molecular depressions of the freezing point of salt solutions of moderate concentration were due to a combination of solvent and solute, Jones and Getman were able to compute the amount of solvent water remaining in the solution by comparing the observed molecular depression with that calculated from the coefficient of ionisation of the solution. The author, after correcting the figures—in which two serious flaws were made—calculated by Jones and Getman, shows that the corrected values point to a regular increase of molecular hydration as the dilution increases, and are, therefore, in accord with the view that ionisation involves an increase, and not a decrease, in the hydration of the solute.

8. The theory may easily be extended to non-aqueous electrolytes in which ionisation may again be attributed to the superior combining power of the ions as compared with the molecules of the dissolved salt.

9. In the case of autolytic salts, which became conductors when fused, it is known that polymerisation is an essential characteristic of these, hence it is only necessary to suppose that the complex molecules of these are associated with the ions. Evidence of the formation of complex ions has recently been obtained in the case of fused salts by Lorenz and Fausti, who have shown that, in fused mixtures of lead chloride with sodium and potassium chlorides, the transport values prove that the lead is present in the form of a complex anion which travels in the opposite direction to the current. Their experiments afford direct evidence of the presence in the fused salt of positive and negative ionic complexes. Conduction in mixtures of solid oxides, such as the Nernst filament, is doubtless electrolytic in character. Like glass, this filament has the composition of an electrolyte, but behaves as an insulator until the temperature has been raised sufficiently to permit ionic migration to take place. Temperature-conductivity curves for filaments of very various compositions have been plotted by Reynolds, and are very similar in form to those for glass, or for overcooled, concentrated, aqueous solutions of calcium chloride or sulphuric acid. An

* Paper read before the Faraday Society.

Digitized by Google

**even more striking resemblance is to be seen between the family of curves given by Reynolds for the conductivity of mixtures of $ZrO_2$ and $Y_2O_3$ at 900, 1,000, 1,100, 1,200, and 1,300 degrees C., and the isothermal conductivity-concentration curves for mixtures of sodium hydroxide and water at 0, 18, 50, and 100 degrees C. The appearance of the two series of curves is such as to warrant the conclusion that the mechanism of conduction is essentially the same in the two cases.**

---

Mr. H. D. LAW pointed out that molecular mobilities were often largely influenced by the undissociated molecules; an ion might wander more quickly through its own molecule than through another. He thought that the experimental evidence on which the hydration was based was as yet somewhat slender.

Dr. C. H. DESCH hoped that Dr. Lowry would develop the theory on the mathematical side. The unsymmetrical pulls, due to electric attractions, on an atom in a solution might be sufficient to cause an interchange of ions, and so explain how conduction occurs in solutions.

Mr. W. R. BOUSFIELD (*communicated*) showed that the experimental investigation of the relation between hydration and ionisation could be approached along three conveying lines: firstly, on the assumption of a rectilinear relationship between freezing-point depression and concentration; secondly, on the assumption that the amount of contraction per gramme of solute, in aqueous solutions, is a measure of the combination between solvent and solute; and thirdly, by a consideration of the variations of ionic sizes with temperature and concentration based on the application of Stokes's theorem on the movement of small sphere in a viscous fluid. The results of these three lines of investigation indicated the generalisation, pointed to by Dr. Lowry, that the amount of combination of solvent with solute increased progressively and continuously with increasing dilution. With regard to the conductivity of water, he inclined to the opinion that the H and OH ions were not entirely anhydrous, but were combined with a smaller proportion of water than any of the other ions, and that the conductivity of water depended upon a volatile organic impurity.

Dr. F. G. DONNAN (*communicated*) drew attention to the work of Werner, who first showed how it was possible to bridge over the gap between the "hydrate" and the "ionisation" theories.

Mr. G. T. BEILBY, referring to the author's views on solid conduction, said that recent observations of his seemed to prove that the impact of electrons—*e.g.*, $\beta$ rays—was able to produce electrolysis—ionisation—in solid crystals, such as calc-spar.

---

## TELEPHONE TRAFFIC.*

BY HERBERT LAWS WEBB, MEMBER.

A paper on telephony before this Institution is under a certain disadvantage, because it is difficult to tell the earnest telephone men anything about telephony that they do not already know, and it is difficult to tell the non-telephone men anything about telephony that they care to know. In attempting to describe the improvements that have been made in the conduct of telephone traffic and to indicate the relation between traffic efficiency and engineering economy, I shall hope at the least to provide a topic for discussion which may interest those members who are not directly engaged in telephony as well as those who are.

I have always held that the study of the traffic is the most important part of a telephone man's work. The chain of reasoning which leads to this conclusion is simple. The sole object of a telephone system is to supply telephonic communication, and telephonic communication consists of hundreds or thousands, or hundreds of thousands, of daily telephone connections. Each connection consists of a certain number of operations, each operation involving a definite performance by apparatus and by a manipulator. Therefore the principal aim of the telephone engineer should be to put the apparatus and the manipulators in a position to execute those various operations with maximum accuracy and celerity. The efficiency—efficiency here meaning accuracy combined with celerity—of the individual connection is the object to be attained, and efficiency of the connection requires efficiency in each step.

Even if the result were solely the supply of the most effective service possible to the public, the accurate and rapid production of the individual connection should be the chief solicitude of the telephone engineer. But the matter goes much deeper than that. It affects the whole engineering design of the system, and it affects both the capital charges and the working costs. Any gain, however slight, in the accuracy or the rapidity of manufacturing the individual telephone connection is felt throughout the whole system. It reduces the size of the plant in proportion to output, and so reduces capital charges, and it reduces the amount of work done in proportion to output and so reduce working costs.

I have read somewhere a remark, attributed to a famous member of this Institution, which aptly illustrates the point. Sitting on a mountain side, he said: "I let fall this grain of sand, and the whole earth feels the shock." Telephone men might well use this as a text. If in a telephone system, where hundreds of thousands, sometimes even millions, of operations are performed daily, we make anyone of those oft-repeated operations more accurate or more rapid, the whole system feels the effect. The gain of a second, or of a fraction of a second, on an operation many times repeated each day, has in a large telephone system a cash value running into handsome figures.

The importance of the study of telephone traffic, then, cannot be over-estimated, and it is clear that the efforts of all who are engaged in the design and conduct of telephone systems are ultimately focussed on the production of accurate and rapid telephone connections. There are many different functions to be performed in a modern telephone system, as there are in a modern battleship; but the true function of the battleship is straight and rapid shooting, and the true function of the telephone system is straight and rapid operating. The cook of the battleship does his share in straight and rapid shooting by keeping the gunners' digestions in order, and in the telephone system even the humble wayleave officer or the storekeeper has his indirect share in the production of accurate and rapid operating.

The improvements in telephone exchange apparatus during the past 10 years have been revolutionary. The history of telephone exchange working, covering now about 25 years, may be roughly divided into two periods—one of about 16 years, in which the apparatus was mainly experimental, and many different systems were tried, but none was produced capable of dealing with a large daily traffic with real accuracy and rapidity; and one of about eight years, in which there has been perfected and standardised apparatus, largely automatic in its working, capable of the greatest accuracy and rapidity in operation. In the old apparatus the percentage of error was very great, owing to the distances between the signals and the jacks and plugs they were related to, and owing to lack of definiteness in some of the signals—on many occasions they worked at the wrong time, and on others they failed to work when required to. With regard to rapidity of operating, the old apparatus was relatively slow in working for a variety of reasons. The distance between the signals and the jacks and plugs imposed a certain strain on the operator's attention and memory, the replacement of signals occupied time, and the lack of definiteness of some of the signals and the total absence of some essential signals necessitated a certain amount of supervision of each connection by one or more operators to ensure a reasonably accurate and satisfactory service.

In the standard apparatus of to-day all these conditions have been changed. The use of lamp signals enables many things to be done which were impossible before. The prime advantages of lamp signals are that they are extremely compact, they have no working parts, and therefore may be placed in any position—vertical, horizontal, or at an angle; they are automatic in action or self-effacing, since the signal disappears immediately the current is cut off; and, finally, they give a much more positive and assertive signal than any form of indicator. These various qualities enable several radical improvements to be made. The signals are placed immediately adjacent to the jacks or cords they control, which, in large switchboards, is impossible with electromagnetic indicators; the line lamp is immediately above or below its corresponding answering jack, and the supervisory lamps are in line with the connecting cords and close to them. With this arrangement the operator loses no time and has to exert no brain power in tracing the relation between the signal and its corresponding jack or cord. The difference in effect between the modern arrangement of directly associating the signals with their corresponding jacks and cords and the old arrangement of placing the signals in a separate part of the board from that occupied by the jacks and cords is something akin to the difference between a telegram in plain language and one in code. In the one case the meaning of the signal flashes instantly to the brain of the operator, and in the other case a certain effort and a certain interval of time are required for translating the meaning of the signal. The automatic working of lamp signals is of much wider range than that of electromagnetic signals. We had self-effacing, or automatically restored, indicators before lamp signals were introduced. But the self-restoring indicator had but two positions—only two words in its vocabulary, so to speak. The lamp signal has several; it may be alight or out, corresponding to the down and up positions of the indicator, but it may also flash, and it may be made to flash at different rates of speed, easily recognisable. Therefore, apart altogether from the fact that it is much more easy to apply to lamps distinctive marks indicating different classes of service than it is to apply such marks to indicators, the lamp signal is able to convey a greater number of meanings as a working signal than an indicator. Finally, the more assertive and positive signal given by a lamp as compared with an indicator is due to a simple physical fact—the great sensitiveness of the eye to light. The glowing of a lamp signal instantly attracts attention, no matter at what angle the lamp may be relative to the eye, and in many cases the lamp is seen instantaneously where a fallen drop would be unnoticed for several seconds. The lamp is seen out of the corner of the eye, so to speak, whereas an indicator must be more directly in the range of vision. The diagrams (Figs. 1,

* Paper read before the Institution of Electrical Engineers, May 11.

Digitized by Google

2, and 3) illustrate the relative positions of the signals and jacks in the three chief types of multiple switchboard.

Perhaps the most striking improvement in operating resulting from the use of lamp signals and the supply of energy from a central source is automatic supervision. In the older systems of working, as has already been said, the indefiniteness and unreliability of the signals made it necessary, in order to reduce as far as possible the percentage of error, that the operator should give each connection a certain amount of supervision. This supervision was directed to ascertaining that the two subscribers had got together all right, and later, in the many cases where the disconnection signal was not given, of ascertaining whether the subscribers had finished talking and the lines could be disconnected. This supervision demanded a certain amount of the operator's time on each connection in excess of the time actually required for the operation of the connection. In the modern switchboard the exact condition of the two subscribers' lines connected is shown by the state of the two supervisory lamps associated with the connecting cords. By the automatic working of these two signals the operator knows when the called subscriber answers, she knows when one subscriber hangs up and the other does not; she knows if either subscriber wants her to come in on the line; and, finally, she knows when the two have hung up. The operator sees these various conditions of the line by the action of the two lamps, and she requires to do no direct supervision. If either subscriber desires to attract her attention he flashes one of the supervisory lamps by moving his switch-hook up and down, and it is only on this signal that the operator goes into the circuit. The

automatic supervision and the automatic and definite disconnection signal afforded by the double supervisory signals constitute an immense advance in the means of handling telephone traffic.

In the working of junction lines—a branch of the operating which is of the highest importance in large systems, since the greater proportion of the traffic passes over the junctions—great improvements have been effected by modern apparatus and methods. The use of lamp signals affords what was lacking before, a positive disconnection signal at the incoming end of the junction. The absence of such a signal was formerly responsible for many operating errors and for much extra work and waste of time. The existence of the supervisory lamp on the cord at the answering position enables the incoming junction operator to signal back automatically to the answering operator if the line wanted is engaged or out of order.

In the accompanying diagrams the average time occupied in the various steps of a connection between one direct line and another is shown for magneto working and for working with modern standard equipment. The explanation of the diagrams is as follows: Zero being the starting point at which the subscriber rings or takes his telephone off the hook, A is the point at which the operator has plugged in and answered, B the point at which she has taken and repeated the number, C the point at which she has tested the line wanted, plugged in and started to ring, and D the point at which the called subscriber answers. From D to E is the conversation, which is not shown on the diagrams, and F indicates the point at which the lines are disconnected after the end of the conversation at E. It will be seen that the total time spent in operating a local connection with magneto working was 14·77 seconds from the beginning of the call to the moment when the operator began to ring the called subscriber, and 17·1 seconds from the end of the conversation to the moment when the operator disconnected the two cords. In the diagrams relating to junction calls the step, B-C, includes the time occupied by the answering operator in speaking by call-wire to the junction operator and getting from her assignment of a junction and in plugging into the

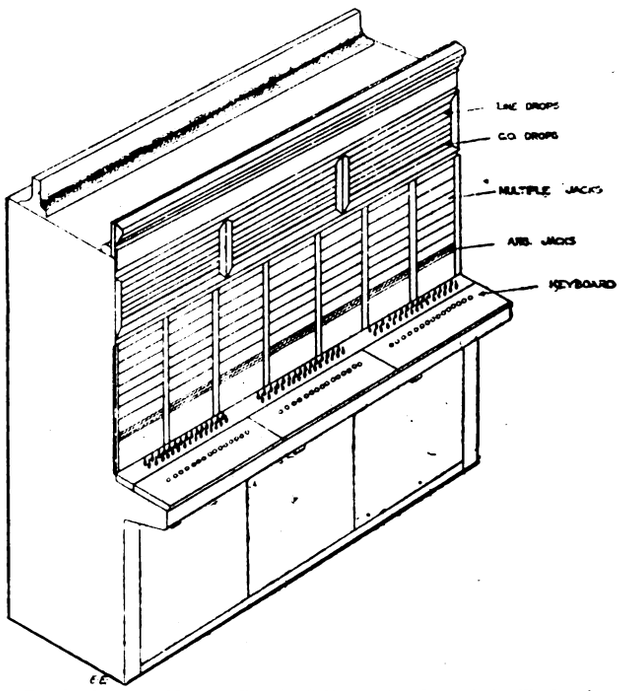

FIG. 2.—Bridging Magneto Board. Self-restoring drops, but still placed apart from jacks and cords which they control.

junction, and the time occupied by the junction operator in testing the line called for, plugging in and starting to ring; during the step B-C on junction connections work is being done simultaneously by the two operators at either end of the junction line.

There are several noticeable points in these diagrams. I should say first of all that the times given are the averages of many thousands of stop-watch observations made by trained

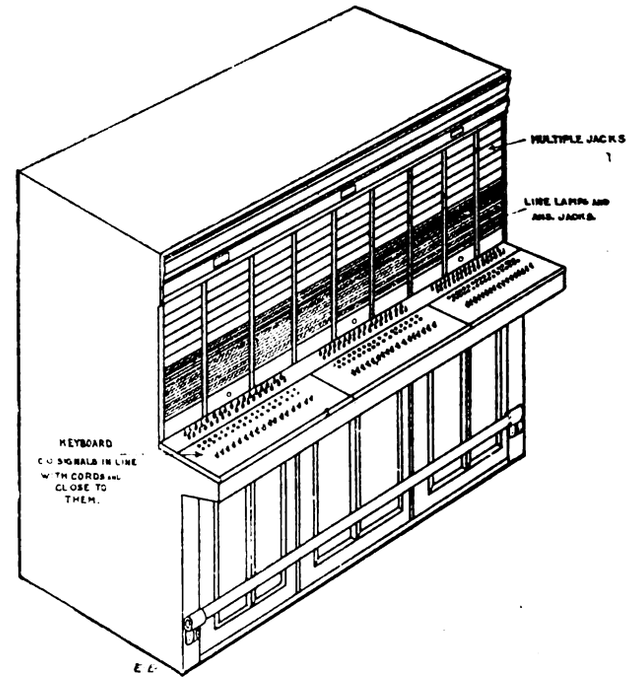

FIG. 3.—Relay Board. Automatic lamp signals placed immediately adjacent to jacks and cords which they control.

observers with special signalling appliances attached to the lines under observation, and the figures indicate with great accuracy the actual average service received by the public. The service observed is that of New York City, where the working was at one time uniformly magneto, though with various types of equipment at different central offices, and is now and has been for the past three years uniformly relay, or common battery, with practically identical equipment at all central offices.

Taking the magneto service, the average time of disconnec-

Digitized by Google

tion, 17·1 seconds, seems long. The explanation is that on many occasions no disconnection signal was received by the operator, either because the subscribers failed to "ring off," or because the signal failed to work. In such cases the operator would only learn that conversation had actually finished by supervision—listening-in. Such a measure being necessary on a large proportion of connections, a high average figure for the disconnection necessarily resulted. Similar conditions would be found on any magneto system to-day where the subscribers have not been rigorously trained to "ring off."

the total time of operating and apparent time of subscriber's answer longer on junction connections.

The really striking features of the diagrams, however, are the great improvements in efficiency resulting from uniform relay working. It is seen that the local connection is operated in 8·55 seconds, as against 14·77 seconds, and the junction connection in 10·92 seconds as against 20·15 seconds, while the delay in disconnection is reduced from 17·1 seconds to 3·08 seconds, a substantial and important gain due entirely to the use of double supervisory signals.

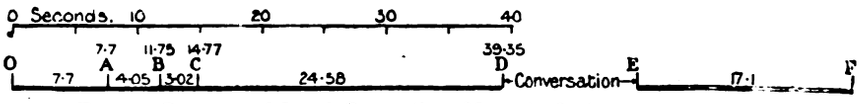

FIG. 4.—Progress of Local Connection, Magneto System.

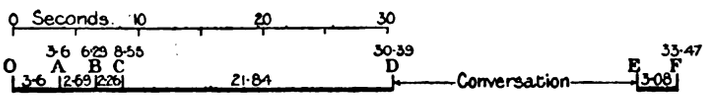

FIG. 5.—Progress of Local Connection, Relay System.

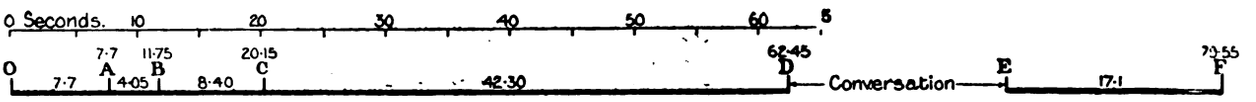

FIG. 6.—Progress of Junction Connection, Magneto System.

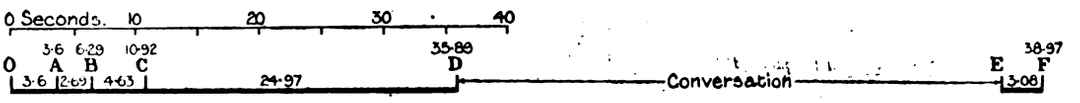

FIG. 7.—Progress of Junction Connection, Relay System

O. Beginning of call. Subscriber rings (Magneto) or takes down Telephone (Relay). A. Operator plugs in and answers. B. Operator takes number and repeats it. C. Operator tests line called for, plugs in and starts ringing. In Junction Connections step B-C includes assignment of Junction by Junction to Operator plugging into Junction by Answering Operator, and testing, plugging in and starting ringing by Junction Operator. D. Called Subscriber answers. E. End of Conversation (duration of conversation is not shown to scale). F. Operator takes connection down.

A curious feature of the service with magneto working is the much longer time taken to complete junction connections, and the diagrams show that the called subscriber's answer was apparently 18 seconds slower on junction than on local connections. As a matter of fact, the diagrams do the called subscriber a slight injustice; he really answers the call somewhat more quickly than the diagrams show. The explanation is that the operations on each connection are not strictly consecutive, as an operator usually deals with several connections at once. This results in breaking the strict continuity of the operations on a given connection; there occur short gaps in the train of operations on each connection, during which intervals operations on other connections are being performed. For the sake of clearness I have not attempted to illustrate this interweaving of operations, but have shown the various steps as if they were performed always consecutively. The natural tendency of operators is to complete local connections first; this slightly increases the gaps in handling trunk connections, and so makes the total time of operating and apparent time of subscriber's answer longer on junction connections.

To show more clearly the gain in efficiency in operating with modern apparatus, I have plotted in Figs. 8 and 9 the total time occupied in operating each class of connection under magneto and relay working, including supervision and allowing five seconds for ringing, but eliminating the called subscriber's delay in answering, and, of course, the conversation. These diagrams show a very striking contrast between the results under old and modern methods. It is seen that the time spent in operating the average connection with standard apparatus is just a third of the time occupied with magneto apparatus; in junction connections the gain is even greater, the time spent in operating the average connection with standard apparatus being less than a quarter the average time with magneto apparatus.

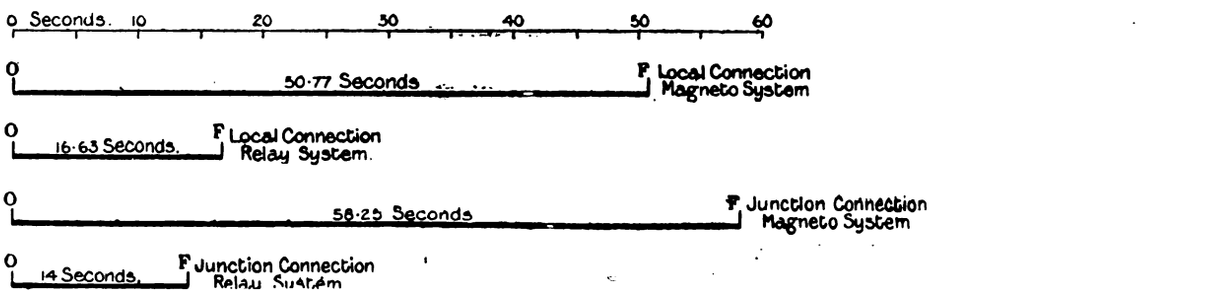

FIG. 8.—Total Operating Time per connection, including supervision and ringing. Junctions in Relay System have Automatic Ringing.

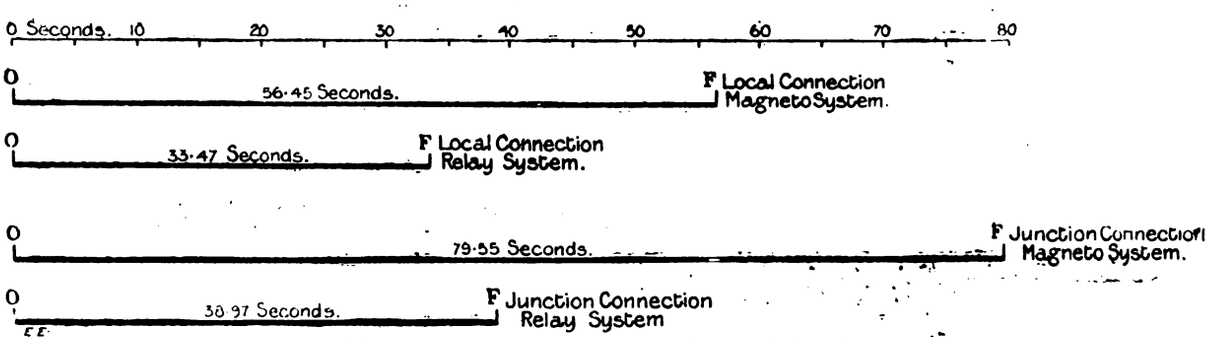

FIG. 9.—Total Time Plant is in use per Connection, exclusive of Conversation.

These figures include that with the apparatus of to-day the operator should be able to do from three to four times the amount of useful work, that is, handle from three to four times the number of calls in a day that she was able to cope with 10 or 12 years ago. It is impossible to give quantitative results of

Digitized by Google

any exactitude, for a variety of reasons. The nature of the telephone call itself varies in different places; in some places there is hardly any junction work and the business is nearly all flat rate, making the average connection a very simple operation; while in other places there is much junction work, and a large proportion of the traffic consists of message-rate calls, party-line calls, call-office calls, and suburban and long-distance calls, which all have their quota of complication and extra work. Moreover, with the great increase in the use of the telephone during the past 10 years, there has arisen a corresponding increase in the fluctuation of the traffic—the busy hour is busier, the sudden rushes are more frequent and more accentuated—and it is the busy hour which, to a great extent, regulates the day's work of the operator in large exchanges, and the day's work of the junction lines in large systems.

For all these reasons it is impossible to establish exact comparisons of quantitative results to prove that the whole gain in efficiency and economy indicated by these diagrams has really been utilised. That a large part has is unquestionable. One instance that has come under my notice, illustrating a very substantial gain in economy, may be mentioned; it is an exchange which formerly contained a magneto equipment for 5,200 lines. The present switchboard equipment of standard apparatus is contained in a room of exactly the same size as the former room—indeed, built over it—and has a capacity of 9,600 lines. To show how difficult it is to make exact comparisons, I may mention that in the present switchboard the answering positions occupy about three-quarters of the space formerly occupied by the answering positions of the old board, whereas the incoming junction positions, though they are more economical, occupy more than twice the space formerly required for incoming junctions, so great has been the increase in the amount of junction traffic.

A saving in time in operating the average connection results in a more economical use of the plant in two ways: first, as the operator can handle more traffic in a day more lines can be terminated at a position, which means, as I have just indicated, a shorter switchboard for a given number of lines, with many attendant economies; and, second, as the plant is used for a less amount of time on each average connection, the daily traffic-carrying capacity of the plant is increased. This has a direct effect on the economy of a very important part of any large system—the junction lines and their necessary switchboard equipment. It has also an effect in reducing the "engaged" trouble—that bugbear of all busy telephone systems. In Fig. 9 the diagrams illustrate the total time that the plant is employed in the unproductive part of the connection, the time that the plant is in use from the call to the second subscriber's answer, and from the end of the conversation to the disconnection. It will be seen that on the local connection the operating period on each connection has been reduced from 56·45 seconds to 33·47 seconds, a gain of 22·98 seconds, and from 79·55 to 38·97, a gain of 40·58 seconds on junction connections. Allowing an average of 120 seconds for the conversation, the result of shortening the time during which the plant is tied up on each connection by 40 seconds is an increase of 25 per cent. in the traffic-carrying capacity of the junction plant.

### Importance of Traffic Study.

It must not be imagined that the great increase of efficiency shown by these diagrams is due solely and entirely to improved methods of signalling and improved apparatus generally. It is also due to more efficient operating and a more thorough study of the minutest details involved in the handling of telephone traffic. It remains true, however, that the improved apparatus is the fundamental cause of the increased efficiency, for with the standard apparatus of to-day we not only get signals having definite meanings, and so eliminate a fundamental defect from telephone switchboards, but we get absolute uniformity of working, and so are able to train operators more effectively and more systematically. We give the operators better tools to work with, tools which involve less mental labour and less physical labour, and we are able to better teach the operators how to use those tools most effectively, both because the whole group of apparatus has become more scientific, and because the study of all the features of telephone traffic has become more scientific. The gain in efficiency of the telephone connection would be much less than it is if the introduction of accurate and automatic apparatus had not been accompanied by the adoption of systematic medods of instructing and training operators, of supervising their work, and of continuously observing and testing the service. The preliminary training of operators is a most important point in a large and complicated system. In the old days, with a variety of types of equipment in use in the different exchanges, it was impracticable to establish a really effective training school. To-day, with uniform equipment in all exchanges, a training school where the embryo operator learns her work by the practical manipulation of the same appliances as she will handle in the regular exchange is a most natural institution. At such a training school more progress is made in a month in turning out an efficient operator than was formerly made in three months by the method of letting learners listen-in at a working position and gradually pick up the work by experiment. In any large system a training school is absolutely necessary for teaching operators the general methods of the work, the proper terms to use, the geography of the exchange districts, and so forth, but the course is relatively ineffective unless it includes practice with the actual appliances the operators are to handle, and practice in answering and completing calls; thorough practice of this kind is difficult to give unless the exchanges have a uniform type of equipment.

The general supervision of the service becomes much more effective with standard apparatus, because the lamp signals are much more easily observable by the supervisors than indicators are. Standing behind the operators at a relay switchboard one can practically follow every movement of the subscribers' telephones; a line signal unanswered or a pair of supervisory signals unattended to glare insistently until the operations demanded are performed. The supervisor's attention is instantly called to any unusual rush of cells, to any difficulty or delay.

The constant observation of the traffic is the measure which has contributed most to the effective use of modern apparatus, and to the attainment of a high standard of efficiency and accuracy in the operation of a large daily volume of telephone traffic. It is only by making continuous tests on a certain proportion of the daily traffic, noting not only the time of every step, but the method and manner of conducting every part of the operation, that sufficient information can be gained of operations involving so much detail to enable defective methods of operating to be eliminated or checked, and suggestions to be evolved tending to a general increase of efficiency.

Some idea of the complexity of telephone traffic may be had from the fact that the form for recording these service observations contains 42 columns, each with its appropriate heading. An entry in each of these columns would not be made for a single call, but the test of one connection might require notes in a fair proportion of the columns, and even if but very few entries are made, each test or series of observations contributes its quota of information relative to the speed, the accuracy, and the general efficiency of the service. To set all these observations out on a diagram would hardly be interesting, and I will only say that the observations give the time in seconds and fifths of every step of the connection, the result of every connection, whether effective or ineffective, and if ineffective from what cause—engaged, don't answer, cut off, wrong number, subscriber left instrument, etc.—the mistakes and omissions of the operator or the subscriber, for even telephone subscribers are known sometimes to make mistakes, and, in short, every ordinary vicissitude that the telephone connection is subject to. The information gained by a large number of tests of this kind, in which observation is made of every detail in the brief history of the telephone connection, is of enormous value in bringing to light the weak spots in the service, whether they be due to defects or faults in the plant, to slowness, inattention, lack of co-operation or lack of method, or erroneous methods on the part of the operators. I hardly like to hint that there may be sometimes lack of method or erroneous methods on the part of the users of the service, who may thus contribute to the errors and delays which sometimes occur in the daily stream of telephone traffic; but if there be, continuous service observations will reveal them, and measures may then be taken to suggest such reforms as seem advisable.

To secure speedy and accurate operation of the vast volume of traffic which flows daily through a large telephone system requires, first, that the apparatus used have signals of definite meaning, that the working of the apparatus be largely automatic, and that the apparatus be of uniform type throughout the system; second, that the operators be thoroughly trained in the manipulation of the apparatus and in the methods of dealing with all varieties of calls before being entrusted with the conduct of actual traffic; third, that the operators be continuously trained to active co-operation with each other, so as to produce general efficiency, and to accuracy and method in every detail; fourth, that a constant study be maintained of the actual conduct of the traffic, directed to the improvement of the standards of accuracy and speed.

## APPOINTMENTS VACANT.

**Manager** for accumulator works. Z K 227, Messrs. Deacon's, Leadenhall-street, E.C. See advertisement.

**Various.**—Northampton Institute, St. John-street-road, London, E.C. Mechanical engineering department: drawing office and lecture assistant, full time, £120; pattern maker and instructor in pattern making, full time, £130; junior drawing office instructor, full time, £100; laboratory demonstrator for the engineering laboratories, full time; junior technical assistant, full time; evening instructor in automobile work, two evenings per week. Electrical engineering department: junior technical assistant, full time; junior lecture assistant, full time. Applications by June 29. See advertisement.

## CITY OF SHEFFIELD—PUBLIC LIGHTING.

**The following is the report of Mr. S. E. Fedden, manager Sheffield Corporation electric supply department, on the public lighting of the city of Sheffield. The report is dated June 6, 1905, and is addressed to the chairman and members of the Electric Light Committee:**

Gentlemen,—I have from time to time considered the possibilities and advantages of electricity for lighting the streets of Sheffield, and have recently acquired a quantity of information on the present condition of electric lighting in the principal cities of the kingdom, a digest of which, together with my observations on the subject, I now have pleasure in submitting to you in the form of a general report.

*General Observations on Street-Lighting.*—The amount of light provided must, of course, be proportioned to the importance of the thoroughfares in question. In some cases it is desirable to exceed the actual requirements of the traffic in order that the effect may be worthy of the surrounding buildings, and increase the attractiveness of the roads by night to the benefit of the tradesmen and the city generally, but in no case should the illumination be less than is necessary for the proper and safe handling of traffic and the convenience of pedestrians, and in this connection stress must be laid upon the importance of uniformity of illumination over the road surface and throughout a strata some 5ft. or 6ft. in height from the ground.

*Modern Conditions.*—Owing to the increase in the height of shop fronts, the width of roads, and the presence of tall tramcars and omnibuses, it is to-day more important for the light to be supplied at a considerable height from the ground, which has the further advantage of keeping the direct rays out of the eye of a person on the road and securing more uniform illumination between the lamps, because the distances between the points of greatest and least illumination and any two lamp globes are more nearly alike than in the case of a short post. Also the rays of light approach more nearly to the vertical, which is a decided advantage, securing better illumination on horizontal surfaces—roadway, sidewalk, tops of vehicles, etc.—where it is needed.

*Comparison of Different Illuminants.*—In order to fairly compare various forms of street-lighting, some precautions must be taken and attention paid to the actual illumination of every square yard of ground in the vicinity of the lamp, avoiding as much as possible directly looking at the source of light and being influenced by its colour and intensity. Many streets at a first glance appear well lit owing to the bright glare of numerous lights on short posts, but a little examination will show that at the surface of the road the effect is very poor and small obstructions are unnoticeable, and when making comparisons of effect and cost between our illuminant and gas several real disadvantages attendant upon the latter should be borne in mind, notably that the bulk of the illumination is not supplied below the horizontal; the necessity for frequent changes of the mantles, the light falling off very rapidly after the first few hours; unless expensive and elaborate lanterns are provided, the gas mantles are very susceptible to the wind, which destroys a large number at certain seasons of the year.

*Electric Lighting.*—The use of electricity for public lighting has greatly increased of recent years, owing largely to the improvement of the lamps and carbons and the cheapening of current supply. I may mention that the particular form of lamp now in use around the town hall—a "long-burning flame lamp"—has only been on the market a few months, although similar lamps burning only a few hours with each trimming, and so unsuited for street work, have been used here and elsewhere for some time now. The modern arc lamp may be relied upon to give a uniform light from the first hour of burning to the last, to be unaffected by wind and weather, and to provide the finest artificial light yet produced by any means. In addition to this the cost per unit of light is lower than with any other illuminant, as subsequent figures will show.

The accompanying list of important towns (Table A) shows the extent to which electric lighting is in use to-day, and a consideration of the populations and general importance of some of these places may well cause one to ask if Sheffield is really one of the best lit cities, as is so often stated.

*Advertisement and Advantage to the Supply Department.*—A satisfactory system of street-lighting is admitted generally to be one of the best possible advertisements for the use of electrical energy, and it removes the reproach sometimes heard that the electricity department exists only for a limited section of the community. The addition of a street-lighting load to our generating plant would be of great advantage to this department, owing to the high load factor of a system of lamps, half of which would burn 4,000 hours and half 2,000 hours out of a possible 8,760. It may be taken approximately that every 100 arc lamps supplied would consume 150,000 units per annum. I append extracts from the recent principal comparisons which have been made between electric and gas lighting in public thoroughfares, and some tabulated details which I have obtained from towns where the system of working is similar to our own. The values given for the light in every case are the results of photo-

TABLE A.—ABSTRACT OF REPLIES RECEIVED FROM VARIOUS TOWNS CONCERNING STREET-LIGHTING, MAY, 1905.

| Town. | Population. | No. of arc lamps. | Hours of burning per annum. | Inclusive charge per annum. | No. of gas lamps. | Charge for gas. | Remarks. |

metric measurement on the spot, and possibly favour gas more than electricity, as presumably the incandescent mantles were more or less new at the time of the experiments, and the light given by them falls off considerably and continuously after a few days of use.

*Unit of Illumination.*—"The Candle-foot."—This unit of illumination employed in the tests may be defined simply as the lighting effect observed with normal eyesight on a surface illuminated by one standard candle burning at a distance of 12in. from that surface. The exact measurement of light in candle-power requires great care and precision of apparatus, and the results are to some extent subject to the personal peculiarities of the observer, but when the instruments are used by the same person for comparative tests only, the errors are generally negligible and a fairer estimate can be arrived at than by any other means.

*Extracts from Paper by Mr. H. B. Maxwell, of Partick, on the subject of Street-Lighting.*

*Note.*—The technical questions in the following notes are to be decided by local conditions and can only be taken as general statements :

"In certain streets in Partick as many as six 3ft. incandescent gas-burners have been displaced by each 12½-ampere arc lamp, with the arc 25ft. from the road level. With the gas lamps there was undoubtedly plenty of light, but objects on the road between lamps at a distance of 100 or 150 yards were indistinct, and in some cases quite invisible, whereas with the arc lamps similar objects were quite clear when 300 yards distant in straight streets. Surely this is the form of illuminant required for street-lighting, for both police and traffic purposes.

"From information received from about 50 towns, the average cost per lamp per annum of incandescent gas lamps (including gas, repairs and maintenance, wages, uniforms, etc., but providing nothing for capital charges or for buying new lamps out of revenue) is :

| | | | |
|---|---|---|---|
| Single 3½ft. to 4ft. burner | £2 | 10 | 0 |
| Two " " burners | 4 | 10 | 0 |
| Three " " " | 6 | 15 | 0 |

"The candle-power of these on the street after 50 hours' use will be respectively 40 c.p., 70 c.p., and 100 c.p. There is not the slightest doubt that a very large number of towns can light their streets with arc lamps as cheaply as with incandescent gas, and with a large increase in light, provided the arc lamps are judiciously placed, and the whole scheme has been carefully designed."

*Official Test of Flame Arc Lamps around Sheffield Town Hall compared with Lucas Gas Lights.*

| Nominal | 5,000 | 2,100 | ·354 | ·467 |
| Mean actual—calculated from all the observations up to 80ft. | 2,694 | 1,202 | ·657 | ·816 |
| Calculated from the observations at 60ft., 70ft., and 80ft. | 2,590 | 1,154 | ·684 | ·850 |

The illumination of the arc lamp at a distance of 120ft. was ·17 of a candle-foot, whilst at a distance of only 100ft. the illumination of the gas lamp was too low to be measured, and was consequently estimated at ·09 of a candle-foot. It also follows from the observations that with arc lamps at 100 yards apart, the illumination at its lowest point midway between any two lamps would be ·2 of a candle-foot.

*Tests at Paddington, London.*—On making certain tests on the lighting of Westbourne-terrace, Paddington, the Gas and Electricity Committee admit that 14 arc lamps give a better result than 56 incandescent gas lamps, and as a result nine main streets and 13 side streets are to be changed over to electric light.

Reference is then made to Mr. Bradley's tests at Westminster, which have been fully dealt with in these columns.—ED. *E. E.*]

*Excerpt from Mr. Pearce's Report on the Recent Electric Lighting of the Streets in Manchester by the Corporation.*

"The six open-type 10-ampere Crompton lamps in front of the infirmary on Piccadilly have been replaced by nine nine-ampere enclosed Gilbert lamps. In addition, 12 six-ampere lamps of the same make have been placed on the centre poles of the tramways running from Portland-street to Mosley-street. The old Brockie-Pell 10-ampere open-type lamps in Albert-square have been replaced by six-ampere Gilbert lamps to the same number. In St. Ann's-square, the old six Brockie-Pell lamps have been replaced by new Gilbert lamps, and two more have been added, one on either side of the centre of the square. These latter took the place of the gas lamps that were taken down. We have, therefore, in all now 45 lamps, and, so far, the new Gilbert type of lamp has given great satisfaction, burning with a clear and very steady light for at least 120 hours without recarboning, trimming, or any attention. The current consumption is, as stated by the makers, 600 watts, or six amperes at 100 volts, equivalent to seven-tenths of a unit per 1,000 candle-power hours.

"Comparing the cost of production for street-lighting as between 'arcs' and the 'intensified gas,' I take the last figure furnished me by the gas department for the latter method, which is at the rate of 1·08d. per 1,000 candle-power hours. I believe this figure also includes 10 per cent. for depreciation.

"*Gas.*—At 4,000 hours of burning. Degree of illumination equivalent to 1,000 c.p. Cost = 4,000 × 1·08d. = £18.

"*Electricity.*—Under the same conditions as above. Number of units used = 4,000 × 7s. 10d. = 2,800. 2,800 × 0·95d., £11. 1s. 6d.; carbon and trimming, 8s.; depreciation 10 per cent., £1. 3s. Cost = £12. 12s. 6d. Equivalent to 0·75d. per 1,000 candle-power hours.

"I have taken the same figure for depreciation for comparison.

"From calculations made I find that the costs of illumination in Albert-square and Sackville-street work out as follows :

*Albert-square Arcs.*

Consumption, 600 watts per hour.
Mean candle-feet (M.C.F.) taken from curves = 2·03.
Board of Trade units per M.C.F. per hour = 600/2·03 × 1,000 = 0·295.
Which at 0·95d. per Board of Trade unit = 0·28d.
Cost per M.C.F. per hour for arcs = 0·28d.

*Sackville-street Intensified Gas.*

Cost of production, 1·08d. per 1,000 candle-power hours.
Equivalent to 0·565d. per 525 candle-power hours.
Mean candle-foot taken from curves = 1·43.
Cost per M.C.F. per hour for gas = 0·565d./1·43d. = 0·395d."

The above calculations, as far as they affect the "arcs," are based on actual measurements taken on the site. These results are based on the results of working of the past few months, and are therefore reliable, and there is only one conclusion to be drawn—viz., "That the electricity department can carry out a system of street-lighting that compares more than favourably with the 'intensified gas system,' both from the point of view of annual cost and illuminating effect."

*(To be continued.)*

## CITY OF LAUNCESTON, TASMANIA.

The following is the report of Mr. Wm. Corin, A.M.I.C.E., A.M.I.E.E., the city electrical engineer, on the working of the electric light and power department for the year 1904 :

1. *Financial Results.*—I am happy to be able to point out that in place of the surplus of £660 which I showed in the forecast in my report for 1903, the year's operations have resulted in a surplus of over £2,000. In making that estimate, I had calculated that a large part of the normal increase in receipts from extended lighting would have been swallowed up by interest on the increased capital requisite for the extensions in hand, which for last year had to be provided in part before any benefit could be derived from the new plant. Fortunately, however, although the interest increased by about £400, the total receipts increased by about £1,500. Again, the previous year had been marked by the renewal of a large number of unsound poles, whilst last year it was not found necessary to renew nearly so many, and the items "wages and material," under the heading "repairs and renewals," were thus reduced by several hundred pounds. The increased surplus is thus accounted for, and as the demand for new connections is not diminishing, there is every reason to believe that this year's receipts will similarly exceed those of 1904. Added to this, as referred to below, many new motors are being connected, so that a still larger surplus may be anticipated for 1905.

2. *Accounts.*—Following on a suggestion published in a recent report of the city treasurer's, I am for the first time this year attaching to this report accounts showing the results of the working of the department during the past year. This suggestion has come at an opportune moment, for from the commencement of last year the accounts have been, as far as possible, kept in the form prescribed by the British Board of Trade for a local authority. I had for long wished to see the accounts in this form, but the high pressure under which the then limited clerical staff was continually working prevented it being attempted before last year. As they now are, the figures can be more easily compared with the published returns of municipal authorities in Great Britain. In addition to the accounts, I have added the usual analysis and tables of technical information, but have abbreviated the latter, omitting some of the less necessary items in order to prevent the appendix becoming too lengthy. I might here with advantage call attention to the fact that the sinking funds and the reserve fund, including last year's surplus, amount to nearly £14,000, the latter alone being about £4,000. The extensions being still in progress, there has not yet been written off capital any amount representing the difference between the original cost of the old plant and its present

Digitized by Google

value, but I presume that from time to time the reserve fund will now be applied to this purpose. Meanwhile the sinking funds are year by year increasing, and the total indebtedness of the undertaking may be regarded as being reduced by an equivalent amount.

3. *Progress with Extensions.*—The past year has seen the completion of the first step in the change over from single-phase to three-phase. Early in the year the first single-phase 100-kw. alternator set was taken down, and immediately the erection of the first three-phase 300-kw. set was commenced. Unavoidable delays occurred, and it was not until June that this set could be finally connected with the water-pipes and started. Even then it was necessary to make very sure before trusting any of the city lighting to it, and some months were spent in testing and adjusting it. Finally, in October it was ready to carry load, and some of the new enclosed street arc lamps and a small part of the city lighting were supplied by it. This enabled a second single-phase set to be put out of service, and the erection of the second three-phase set to be proceeded with. Until the latter was erected and in running order, I deemed it inexpedient to trust to the first set to run continuously, and, therefore, with some difficulty, arranged that the load could be changed at the sub-station from single-phase to three-phase, or *vice versâ*, at a moment's notice. Although the consequent switching arrangements were somewhat complicated, subsequent experience showed that this provision was well judged, as but for its aid continuity of supply during the transition period could not have been maintained. It was not until last month that the difficulty in this direction was over, when the contractors placed the services of the two machines at our disposal. Since then one or other of the three-phase machines has been running continuously, and the temporary switching gear has been dismantled. Nearly the whole of the lights and motors of the central area of the city are now supplied from the new machinery, by means of the 360-kw. transformers and the low-tension underground feeders described in my last report. The results are quite satisfactory wherever the work on the overhead distributing mains, rendered necessary by the change, has been finished. This work is now rapidly approaching completion, and at the same time the changing over of the outer residential circuits is being vigorously pushed on, and will probably be complete by June. The third three-phase generator will probably be running within three weeks from now, and the fourth will be commenced immediately afterwards. The work on the pipe for duplicate water supply from the mouth of the tunnel is well under way, but its completion will have to wait until all the load is changed over to three-phase.

4. *Street-Lighting.*—Some of the new arc lamps were supplied from the three-phase plant in October. Of the remainder, some were put into service during November, and the change was completed on Dec. 22. The necessity of pushing on with the alterations to the private lighting circuits has hitherto prevented some of the arc lamps from being properly hung. Several are not yet in position, and a large part of this work is at present only temporary. When complete the majority of the lamps will be suspended over the centre of the streets. Whilst on the subject of street-lighting, I may remark that it was a matter of considerable difficulty last winter to carry the maximum load with only four machines, one of the single-phase machines having been dismantled, and the first new three-phase machine not being ready for running, and I therefore had to devise various expedients for reducing the load. Amongst others, the street lamps, which normally are 25 c.p., 32 c.p., and 50 c.p., were temporarily reduced to 16 c.p. It is noteworthy that in spite of this reduction no complaint was ever received of diminished light in the streets, although the candle-power was in many cases reduced to less than one-third of its former value. This seems to indicate that the public eye gauges an incandescent lamp used for street-lighting by the intrinsic brilliancy of the filament, rather than by the amount of light shed around.

5. *Motors.*—The month of October saw the first three-phase motor started at work. This was of 18 h.p., and was supplied to the Tasmanian Woolgrowers' Agency Company for a hydraulic dumping press, elevator, etc., in connection with their new wool stores and salerooms. The working of this motor, I am informed, is all that could be desired. There are now 46 three-phase motors, totalling 119 h.p., at work, and all are giving the greatest satisfaction. There are yet 41 motors, totalling 126 h.p., waiting to be changed over, and we have additional orders from new consumers for 15 motors, totalling 138 b.h.p., making altogether 102 motors, and a total of 383 b.h.p. at work or on order. I need scarcely remark that a considerable increase of revenue may be expected from this source.

6. *Testing-Room.*—The new testing-room at the sub-station has already justified its existence. As regards incandescent lamps, the addition of an accumulator or secondary battery and other minor improvements have so facilitated the work that it can now be carried out with the maximum of ease and comfort. Five per cent. of every batch of lamps received are tested for candle-power and efficiency, and 1 per cent. for life. Any consignments below a certain standard are rejected, and payments are made according to the result of the average life tests. As illustrating the value of this work, recently our contractor, being unable to supply some 16-c.p. lamps at short notice, a consignment was ordered from another manufacturer. Out of 984 received only 156 were within the limit, and the candle-power of the others averaged about 12, some being less than 8 cp. Had we not been systematically testing these would have been distributed to the public, but I need scarcely say that they were rejected and not paid for.

*Conclusion.*—A glance at the present position of the undertaking shows that the prospects for the immediate future are extremely encouraging. The capacity of the plant has been practically trebled for a comparatively low expenditure. In spite of the consequent augmented capital and increased interest charges, the receipts are increasing in a greater ratio, so that the new plant will be profit-earning from the start. As I showed in a recent memorandum, after providing for the lights and motors now connected, and between 300 h.p. and 400 h.p. for trams, additional motors to the extent of another 1,000 b.h.p. may yet be connected without overloading the plant. I, therefore, venture to express the hope that the suggestion already made to seriously consider the question of trams may be put into effect at an early date. I need scarcely state that the results referred to above have not been accomplished without very considerably increased work, not only to myself, but to all the staff; and, in conclusion, I wish to put on record my appreciation of their services.

ANALYSIS OF ACCOUNTS AND SUPPLY RECORDS FOR YEAR ENDED DEC. 31, 1904.

*Financial Position.*

| | |
|---|---|
| Amount of loans sanctioned | £160,000 |
| Amount borrowed | 127,097 |
| Amount expended | 139,984 |
| Amount of sinking funds | 9,908 |
| Amount of reserve fund | 1,811 |
| Total of items 4 and 5 | 11,719 |

*Financial Results for Year ended Dec. 31.*

| | 1904. | 1903. |
|---|---|---|
| Completed year of working | 8th | 7th |
| Capital expenditure at end of year | £139,984 | £115,580 |
| Revenue from lighting rate | £3,272 | £3,104 |
| Revenue from electricity supply | £8,929 | £7,545 |
| Revenue from rental of meters, motors, and fittings, and from other sources | £1,091 | £1,043 |
| Total revenue | £13,292 | £10,692 |
| Total costs | £4,391 | £5,116 |
| Gross profit before providing for interest and sinking fund | £7,901 | £5,576 |
| Percentage of gross profit to average capital | 6·19 | 4·91 |
| Interest on loans, less interest receivable | £4,191 | £3,781 |
| Sinking fund contribution | £1,531 | £1,143 |
| Percentage of ditto to average capital | 1·20 | 1·00 |
| Financial results after payment of all charges, including interest and sinking fund, surplus | £2,179 | £745 |

*Supply Records.*

| | | |
|---|---|---|
| Number of 8 c.p. lamps connected at end of year (arc, incandescents, and motors equivalent in 8-c.p.) | 44,221 | 38,677 |
| Average for the year | 41,797 | 36,368 |
| Number of units sold— | | |
| Private supply | 493,226 | 442,015 |
| Power and heating, other departments and workshops | 20,240 | 16,752 |
| Street-lighting | 244,958 | 248,550 |
| Total units sold, private and streets | 758,424 | 707,317 |
| Units sold per 8-c.p. lamp (connections during year averaged) | 18·15 | 19·45 |
| Maximum load reached, including arc lamps | 513 kw. | 575 kw. |
| Load factor | 16·83 | 14·0 |
| Capacity of plant at end of year | 600 kw. | 548 kw. |
| Average price obtained per unit— | | |
| Private supply, including other departments, etc. | 4·17d. | 3·95d. |
| Street-lighting | 2·23d. | 2·03d. |
| Total supply | 3·55d. | 3·27d. |
| Population of area supplied (last census) | 19,700 | 19,700 |

Prices charged: Private lighting, maximum demand system, with initial charge of 6d. per unit for daily average of two hours, and 1½d. per unit after. Private lamps in streets, half rates. Power and heating, 2d. per unit for first 200 units per quarter, per brake horse-power, or kilowatt, 1d. per unit after. Motors and heating apparatus for other departments, ½d. per unit. Street-lighting paid for by lighting rate.

*Analysis of Costs.*

| | 1904. £ | 1904. Per unit. d. | 1903. £ | 1903. Per unit. d. |

# LEGAL INTELLIGENCE.

## PRODUCTION OF TRAMWAY TICKETS.

At the Nottingham Guildhall last week Mr. W. W. Simpson, secretary of the Derby and Nottingham Electric Power Company, was summoned for refusing to produce his ticket when travelling on one of the Corporation trams

Mr. STEVENSON, on behalf of the Corporation, stated that the defendant seemed to have the idea firmly fixed in his mind that he need not deliver up his ticket when travelling on the tramways. When an inspector got on to the car and asked him for his ticket, Mr. Simpson refused to produce it, saying, "I have thrown it over the side." Defendant also refused to pay the fare when requested. After quoting the by-law under which the proceedings were taken, Mr. Stevenson pointed out that the case was of very great importance, because if people acted in the way that the defendant had done the business of the Corporation would be completely disorganised.

Evidence having been given by the inspector, the DEFENDANT deposed that when he paid his fare he was offered a ticket, but he refused to take it, as he had done on several previous occasions. When asked by the inspector for his ticket he said that he had been so insulted of late by inspectors that he had ceased to take tickets, and had not taken one on that occasion.

Cross examined by Mr. Stevenson, defendant stated that when offered a ticket, he told the conductor that he "would not touch the accursed thing."

Mr. GREEN, for the defendant, said there was no by-law which compelled a passenger to take a ticket when he paid his fare, and if a man refused to take a ticket he could not be summoned for not producing one.

The CHAIRMAN: We are perfectly clear that he took a ticket on this occasion.

Mr. GREEN said that it was no business of Mr. Simpson's to act as a servant of the Corporation in checking the honesty of their employés by taking tickets, and Mr. Simpson had now adopted the attitude of paying his fare just before getting off.

The CHAIRMAN said it was quite clear that the offence was committed, and imposed a fine of 20s.

A summons for a similar offence on May 22 was then heard.

According to the prosecution, the defendant, in this case, was asked for his ticket as he was about to leave the car, and he replied that it was "on the top."

The Bench held that this was not "producing" the ticket, and, in fining the defendant 10s., said they were prepared to state a case if necessary.

# COMPANIES' MEETINGS AND REPORTS

## ELECTRIC AND GENERAL INVESTMENT.

The directors recommend the payment of the following dividends, etc., for the year ended May 31: ordinary shares, a dividend of 4s. per share, of which 1s. per share was paid on account in January last, leaving 3s. per share to be distributed; the trustees for the ordinary shares reserve fund propose to distribute out of the dividends received 1s. per share, making a total present distribution of 4s. per share, or 20 per cent., or a total distribution of 5s. per share, or 25 per cent., for the year; founders' shares, a dividend for the year ended May 31 of £20 per share; the trustees for the founders' shares reserve fund propose to distribute out of the dividends received £10 per share, making a total present distribution for the year of £30 per share. The above-mentioned payments will be subject to the deduction of income tax.

## CHADBURN'S (SHIP) TELEGRAPH.

The report for the year ended March 31 shows the balance to the credit of the profit and loss account to be £18,095, less managing director's remuneration, directors' fees and expenses, depreciation on properties and plant, £8,234—£9,860. From this amount £6,000 must be deducted, being dividends which have been paid at the rate of 6 per cent. per annum on the preference shares and an interim dividend of 8 per cent. per annum on the ordinary stock, leaving the sum of £3,860. This sum, together with the balance carried forward from last year, makes a total of £11,187. 3s. 8d. to be dealt with. The directors propose to pay a dividend on the ordinary shares of 12 per cent. per annum, less income tax, for the half-year ended March 31, making, with the interim dividend already paid, a dividend of 10 per cent. per annum for the 12 months, carrying forward a total balance of £7,587. The year's working has, state the directors, been extremely satisfactory, and a large amount of very profitable work has been carried out, independent of the ordinary telegraph business. They consider this a favourable opportunity to write off a larger sum than usual under the head of depreciation in reduction of the amount appearing in the balance-sheet for goodwill, patents, etc. New works have been purchased in Cyprus-road, Bootle, and they have now been in full operation for over 12 months. The results have shown an economy in working.

# LIENS REGISTERED.

**Barbados Light Railway, Limited, Westminster.**—Lien registered, June 1, for £6,000 5 per cent. debentures. Holder: C. J. P. Cave, Petersfield, Hants. Charged on the railways, plant, and rights, etc., in the island of Barbadoes, the undertaking, and all other property, present and future.

**Woking Electric Supply Company, Limited.**—Issue on May 6 of £150 debentures, part of a series created Nov. 2, 1899, to secure £25,000. Charged on the company's undertaking and property, present and future, including uncalled capital. No trustees. Total amount previously issued of same series, £24,850.

**Diesel Engine Company, Limited.**—Issue on May 27 of £15,000 debentures, being the whole of a series created May 26, 1905. Property charged: the company's undertaking and property, present and future, including uncalled capital. No trustees.

# CONTRACTS FOR ELECTRICAL SUPPLIES.

**Panama.**—The Municipality will shortly require tenders for construction of an electric tramway.

**Hornsey.**—The Town Council invite tenders for switchboards and brackets for arc lamps. Tenders by June 19.

**Darlington.**—The Corporation invite tenders for switchboard extension and booster. Tenders by June 19.

**Aston Manor.**—The Corporation invite tenders for the electrical equipment of their overhead tramways. Tenders by June 23.

**Grays Thurrock.**—The Urban District Council invite tenders for switchboard extension, storage battery, etc. Tenders by June 17.

**Paddington.**—The Guardians invite tenders for rewiring the whole of the electric bells at their infirmary in the Harrow-road. Tenders by 5 p.m. on 20th inst.

**Leigh (Lancs.).**—Tenders are invited for the supply of one water-tube boiler for the electricity department. Tenders by July 1. See advertisement in last issue.

**Rosario de Santa Fe Argentine.**—The Municipality require tenders for the construction and working of electric tramways in the town. Tenders by July 30.

**Kingston-upon-Hull.**—The Electric Lighting Committee invite tenders for the supply, delivery, and erection of various plant. Tenders by June 22. See advertisement in last issue.

**Bristol.**—Tenders are invited for single-phase alternating-current transformers and three-phase to direct-current motor-generators. Full particulars from the City Electrical Engineer, Temple Backs, Bristol.

**Stepney.**—The Electricity Committee invite tenders for the supply during the year ending June 30, 1906, of ampere-hour meters, demand indicators, and arc lamp carbons. Tenders by noon on 28th inst. See advertisement.

**Rotherham.**—The Corporation invite tenders for the supply and delivery of cable and meters according to their requirements between July 1, 1905, and June 30, 1906. Tenders by 26th inst. Full particulars in advertisement columns.

**Stalybridge.**—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

**London, W.**—The Great Western Railway Company invite tenders for the supply, delivery, and erection of the following plant in connection with their electricity generating station at Park Royal: (Specification 18) pipework, feed and other pumps, tanks, feed heaters, water-softening and oil-separating plant, etc. Tenders by 10 a.m. on 26th inst.

Digitized by Google

## RESULTS OF TENDERS.

**Exeter.**—The Corporation have accepted the tender of Dick, Kerr, and Co. for two cars and equipments.

**Burnley.**—The Corporation have accepted the tender of Dick, Kerr, and Co. for one 500-kw. direct-current generator.

**Metropolitan Electric Supply Co.**—The tender of Dick, Kerr, and Co. has been accepted for two 500-kw. motor-generators.

**Batley.**—The Corporation have accepted the tender of Dick, Kerr, and Co. for 5¼ miles permanent way and overhead equipment.

**Partick.**—The Municipality has placed with Messrs. Bruce Peebles and Co. an order for a 600-kw. direct-coupled set for their lighting station.

**Hammersmith.**—The Electricity Department have accepted the tender of E. Bennis and Co., at £747, for a complete coal and ash elevator conveyor plant.

**Johannesburg.**—The Municipality have accepted the tender of Dick, Kerr, and Co. for 100 single-truck top-covered cars and equipments and two watering cars.

**Portsmouth Dockyard.**—The tender of Bennis and Co. has been accepted for 20 Bennis stokers and furnaces, shafting, gear, etc., through E. Danks and Co. (Oldbury), Limited.

**Ashton-under-Lyne.**—The Corporation have accepted the tender of Dick, Kerr, and Co., Limited, Abchurch-yard, Cannon street, London, E.C., for six tramcars and equipments.

**Burton-on-Trent.**—The Corporation have accepted the tender of Messrs. Edward Bennis and Co. for four Bennis patent machine stokers and new patent self-cleansing compressed-air furnaces.

**Northampton.**—The Northampton Electric Light and Power Company have accepted the tender of Messrs. Edward Bennis and Co. for complete coal and ash elevating and conveying plant, coal-bunkers, etc., at £862.

**Blackpool.**—The Corporation have accepted the tender of Messrs. Bennis and Co. for two Bennis patent stokers and self-cleansing compressed-air furnaces for Lancashire boiler, and automatic steam regulator.

**Heywood.**—The Town Council have accepted the tender of R. W. Blackwell, 59, City-road, London, E.C., for the construction of the permanent way and paving and overhead electrical equipment of about four miles of tramways.

**Trefriw (Denbighshire).**—The Hart Accumulator Company, Limited, Marshgate-lane, Stratford, London, E., have secured the order for the supply of a battery of 120 of their standard lighting type cells required at the electricity works.

**Scottish Central Power Co.**—Messrs. Bruce Peebles and Co. have secured a contract for the extension of the above company's generating plant. The contract includes 3,000 h.p. in steam alternators, condensers, switchboard, etc. The price is £17,000.

**Kettering.**—The Urban District Council have received the following tenders for Nernst lamps:

Total of tender with type "A" brackets.

**Durham Collieries Electric Power Supply Co.**—Messrs. Bruce Peebles and Co. have secured an order for a 9,000-h.p. generating station complete, at £92,000, from the above company.

**Stoke Newington.**—Ferranti Limited have received, through Bruce Peebles and Co., Limited, the order for the transformers required for stepping down 10,000-volt three-phase current to supply motor-generators. The ratio of the transformers is 10,000/500, they are oil cooled, and the total capacity is about 350 kw.

**Thirsk.**—The Parish Council have accepted the tender of the Northern Counties Electric Supply Company for the lighting of Thirsk for 1905-1906. The contract price is 29s. 6d. per 40-c.p. lamp per year as against 31s. paid to the electric light company previously. The Northern Counties Electric Company has also secured the contract for lighting Thirsk Junction railway station.

**Moxley (near Bilston).**—The South Staffordshire Joint Small-pox Hospital Board have received the following tenders for the electric wiring and lighting (including main cables, fittings, etc.) at the small-pox hospital:—

# BUSINESS NOTES.

## TRACTION.

**Grimsby.**—The Corporation and the company have come to terms by which the latter will extend their system.

**Leeds-Wakefield.**—Electric trams are now run from the centre of Leeds to the centre of Wakefield, a distance of 10 miles.

**Bolton.**—The Tramways Committee have decided to grant their motormen, conductors, and night-shed men four days' holiday per annum with pay.

**Eccles.**—The electrical engineer has been instructed to obtain from the Salford tramways manager definite information as to the quantity of electrical energy required for working the tramways within the borough of Eccles.

**Russia.**—It is reported that in view of the great lack of efficient electricians on the Russian railways the Minister of Ways of Communication has decided to establish special electricity schools on all the Government railways.

**Anglo-Argentine Tramways Co.**—The directors have declared an interim dividend on the preference shares of 2s. 9d. per share, less income tax, for the half-year ending June 30, on which date the dividend warrants will be posted.

**Bournemouth.**—Some little delay appears to have arisen in the completion of the transfer of the company's business to the Corporation, at which the latter are manifesting symptoms of impatience, as they are anxious to link up the systems. A complete scheme of fares has been prepared.

**Bristol.**—At a meeting of the inhabitants of Warmley, the following resolution was carried unanimously: "That the chairman be asked to present the resolution to Mr. Samuel White personally to consider it with the greatest possible care, and give them the greatest facilities to get the extension carried out at once."

**Signalling by Wireless Telegraphy.**—The Chicago and Alton Railway has prepared a section of its system and rolling-stock to conduct tests with a wireless telegraphic device. It is proposed to equip engines with instruments by means of which wireless signals may be exchanged between trains so as to avoid disasters.

**Halifax.**—A special meeting of the Town Council has been convened for to-night, when a proposal to construct a line of tramways from the terminus at Salterhebble to the Calder and Hebble Inn, at an estimated cost of £6,400, will be considered. A loop line is to be constructed on the Triangle section at a cost of £250. A proposal to introduce an eight-hour day was negatived as impracticable. The employés work nine hours per day.

**Railway Electrification in America.**—It is reported that electric traction is to replace steam power on the Chicago and Evanston line of the Chicago, Milwaukee, and St. Paul Railway, and that the line will be operated by the North-Western Elevated Railway, which will connect with the surface line by an extension from its present terminus at Wilson-avenue. All passengers and freight traffic will be handled by electricity north of this point, and within a few years the railway will be elevated from Wilson-avenue to the city limits.

**Croydon.**—The Corporation have decided to give the British Electric Traction Company notice of determination of the latter's lease on May 31 next. An independent engineer is to be engaged to report to the Corporation upon the condition of the system. The town clerk has been instructed to take such steps against the company as may be necessary for the restoration of certain feeder cables, regarding which the Corporation have been in communication with the company for some time. The borough electrical engineer reports that, in general, the rails and equipment are in a satisfactory condition.

**Darlington.**—At last week's meeting of the Tramways Committee a report of a somewhat unsatisfactory nature regarding the ½d. fares was given. During May the revenue per car mile was only 6·35d. as

Digitized by Google

against 6·63d. in April. The receipts for the four weeks ending May 27 were £779. 0s. 3d., £112 less than in April. The number of passengers carried was an increase, being 241,655 against 225,419, so that onus of the decrease apparently rests on the new ½d. fare system. The car mileage for May was 29,434·4, comparing with 28,625·5 for the previous month. A much larger increase in passengers than has obtained was expected by the committee.

**Yarmouth.**—The accounts for the past year show that the total income amounted to £8,736. 8s. 3d. (an increase of £960. 3s. 9d. on the previous year), and the expenditure amounted to £6 348. 6s. 6d., leaving a gross profit of £2,388. 1s. 9d. (an increase of £450. 11s. 11d.), which, after deducting interest and sinking fund charges, leaves a net profit of £284. 1s. This amount, with £191. 3s. 4d. balance from previous years, makes a surplus of £475. 4s 4d. It was resolved to place £400 to a depreciation fund, and carry the balance of £75. 4s. 4d. forward. The Queen's-road extension has materially contributed to the increased receipts. The number of passengers carried during the year was 1,821,200. It is hoped that the Gorleston section will be ready early next month.

**Walsall.**—The following recommendations figure on the Town Council's agenda: "That an arrangement be entered into with the Wolverhampton and District Electric Traction Company, Limited, under which the Corporation shall have the right to run 'through' cars over the company's line to and from the Market-place, Willenhall, on such terms and conditions as may be agreed upon by the Tramways Committee and the company. That the Corporation extend their tramway from its present terminus on the Walsall-road, Willenhall, for about 18 yards, so as to form a junction with the tramway of the Wolverhampton and District Tramways Company, Limited, at an estimated cost of £200, and that the town clerk be authorised to make application to the Board of Trade for their approval to such work being carried out."

**Automatic Signalling.**—The North-Eastern Railway Company have had installed on the 11 miles' stretch of their main line, extending from Green Lanes, Thirsk, to Alne Station, a system of automatic signalling. Recently the system was examined by Lieut.-Colonel P. C. von Donop on behalf of the Board of Trade, and last week the new method was brought into regular operation. The system, which was installed by the Hall Signal Company, of New York, is designed to enable the services of signalmen, except at points of junction, to be dispensed with, and is purely automatic, the necessary connections being set up by the trains themselves. The valves for admitting the air to the operating cylinder are electrically controlled. The arrangement is expected to materially increase the capacity of the line.

**Woolton.**—The question of linking up Woolton with the Liverpool tramway system came before the District Council the other day, when Mr. M'Guffie moved the following resolution: "That the Council take steps to devise and determine the best route to bring electric trams into Woolton, and the course to adopt so that the ratepayers will participate in any profits arising therefrom." He asked to be allowed to divide his motion in three parts: first, as to the desirability of having electric trams; second, that parliamentary powers should be secured, unless advantageous terms could be made with the Corporation of Liverpool, or others; and third, as to the best route for the line to take. As no seconder was forthcoming, the matter dropped. The general opinion appeared to be that with two 'bus routes and three railway stations the district was sufficiently served.

**Belfast.**—At Tuesday's meeting of the Tramways Committee consideration was given to the question of the fares. The sub-committee, which had met on the 6th inst., recommended the adoption of a further report by the manager (Mr. Andrew Nance), submitting a scheme of lengthened 1d. stages, with a 2d. maximum fare, which the manager stated he had endeavoured to frame upon the principle of making it as convenient as possible to the greatest number. After some discussion, the report was adopted, subject, of course, to confirmation by the Council. The city surveyor (Mr. H. A. Cutler) reported that he was not yet in a position to proceed with the conversion of the trams on Shore-road as the Antrim-road was about to be taken in hand, and the Cavehill and Whitewell Tramway Company would commence work on their line simultaneously with the Corporation contractors, so that it was necessary that the Shore road should be kept open for the traffic which would be diverted from the Antrim road. A deputation attended and, on behalf of the residents of Ardoyne and Ligoniel, asked for tramway facilities, and after considerable discussion the manager was instructed to provide a service *via* Shankhill-road to Ardoyne.

**District Railway.**—Tuesday witnessed the disappearance of the steam locomotive from another section of the District Railway, the branch from South Acton to Hounslow Barracks being now worked by electricity. The new service of electric trains was successfully put into operation without ceremony. This new section is some 6½ miles in length. July 1 is the day on which electricity was expected to be adopted generally on the system of the District Company, but it may be that the period will have to be extended. There have been unlooked-for delays in the delivery of the rolling stock, and it is the intention of the company that the electric service on the circular system shall not be started until they are in a position to run it in its entirety, they being anxious to avoid the half-and-half policy. It is stated officially, however, that on the main stretch of line, running from east to west, electric trains will be running in the very near future, probably by the end of July. The whole line is, in fact, ready now, and the company only awaits a sufficient number of cars. Automatic signalling will come into operation with the working of the line by electric traction. This system has already been submitted to an exhaustive trial, lasting over two years, on the Mill Hill Park to Harrow branch and has given every satisfaction. It is claimed that this system is "fool-proof" and that it is impossible for a train to over-run a signal that stands at "danger." It is expected that this will enable something like double the number of trains to be run.

**Burnley.**—At the meeting of the Corporation the recommendation submitted by the Joint Tramways and Electricity Committee, that the duties of the tramways manager be revised so as to limit such duties strictly to the management of the traffic on the tramways, and that the duties of the borough electrical engineer be revised so as to include the management and supervision of all the electrical undertakings of the Corporation, was carried, subject to an amendment that the resolution read "be revised if found necessary." A sub-committee has been appointed to visit other towns for the purpose of making enquiries as to the duties of the borough electrical engineer and tramway manager respectively. A councillor has given notice of the following motion, which he has agreed to leave over until after the joint committee have reported: "That this Council is of the opinion that the public interest will be better served in regard to efficient service, economical administration, and freedom from official friction by a reform of our tramway and electrical departments so as to secure (1) the amalgamation of the two departments under one committee; (2) the appointment of an electrical engineer who shall have full control over both the electrical and tramway departments; (3) the appointment of a traffic manager who shall be subordinate to and under the control of the electrical engineer. Such rearrangement, subject to due regard being paid to existing contracts, to be brought into operation as soon as possible."

**Newcastle.**—At last week's meeting of the Corporation, the tramway returns for the year ended March 31 were presented. The income totalled £197,849 against £185,027 for the previous year, the receipts per car mile working out at 10·98d. against 10·94d., an increase of ·04d. The expenditure represented £127,018 against £121,557, the amount per car mile being 7·05d. against 7·19d., a decrease of ·14d. The car mileage for 1904-5 has been 4,326,152 as against 4,059,907 last year, an increase of 266,245. Salaries and wages showed a slight increase, and the cost of power and distribution expenses amounted to £10,628 against £9,751. The gross profit on the year's working, after adding a small amount for sundry items, is £70,936. 11s. 8d. as against £63,469. 18s. last year, an increase of £7,466. 13s. This is to be disposed as follows: to amount written off stocks on revaluation, £923. 0s. 7d.; amount deducted from profits for money stolen from traffic receipts at Byker depôt on Jan. 1, 1905. £57. 13s. 9d.; interest on loans, £33,944. 5s. 7d.; redemption, £89,717. 13s. 4d. These together leave a net profit on the year's working of £6 293. 18s. 5d. The balance remaining from the previous year was £3,681. 1s. 6d., so that the total surplus is £9,954. It is reported that in addition there is a sum of £10,000 to be taken into account. This had been lent to the Education Committee, but has been paid back and invested at 3¾ per cent. interest. This sum, added to the £9,945 mentioned above, brings the sum to be dealt with up to £19,954. It is proposed that the Council should invest this sum as a nucleus for depreciation. There has been paid off in redemption £83,371, of which £81,318 has been entirely extinguished, and £2,053 has been invested in a sinking fund. The accounts will be considered at a special meeting of the Tramways Committee to-night.

**Heywood.**—At the meeting of the Corporation the town clerk submitted draft agreement prepared by him with Bury and Rochdale Corporations for working the Heywood tramways, and it was resolved, "That the agreement be approved and submitted to the Corporations of Bury and Rochdale for their consideration." Councillor Popple subsequently proposed the adoption of the minutes of the Tramways Committee. He stated that during the past month the average of the daily receipts was £11. 16s. 6d.; for the previous month it was £11. 7s. 8d. and for the month prior to that £9. 18s. 2d. Referring to a communication received from the Lancashire Electric Power Company, he stated that the Heywood electrical engineer and the consulting engineer (Mr. Salter), travelling somewhat different roads, had come to the same conclusion, which was that they should be able to produce electricity at about 1½d. instead of 3d. per unit. Mr. Salter had stated that he would be disappointed if the cost of the current in Heywood did not come down to 1d. per unit If Heywood decided to purchase power from the Lancashire Electric Power Company, that company would have to lay miles of cables largely through a hostile country, and they would have to obtain wayleaves from landowners before they could lay their cables. Their nearest works were at Outwood. If Heywood bought electricity from the company they would receive the current at a high tension, and the Corporation would have to supply machinery to reduce the tension and distribute the current. Therefore, instead of getting the current for 1·3d. per unit, it would cost Heywood about 2½d. per unit. In the first report given by Mr. Salter it was stated that they would have to spend £8,000 on the electricity works in order to provide the required current, but that estimate had since been reduced to £6,000. Taking all things into consideration, the committee had decided to generate their own electricity. The minutes were adopted.

**Light Railways.**—Applications to the Light Railways Commissioners are now pending in reference to systems for Yorkshire and Lincolnshire. It will be remembered that an application was made early this year to the Commissioners by the promoters of the Ackworth and Immingham Light Railway, which it was proposed to construct from the Ackworth coal mines to the new Humber Dock at Immingham. An enquiry was held, and the Commissioners refused their sanction, stating that the undertaking, which proposed to cross the Trent, was of such magnitude that it needed a parliamentary enquiry. The proposal has now been revived in a modified form, but in two sections, and the projected bridging of the Trent has been abandoned. The new scheme differs considerably from the old, which was substantially for a line from the Ackworth mines roughly, parallel with the Lancashire and Yorkshire Railway from Pontefract to Goole, and thence parallel with the Marshland railway to Trent side, where it was proposed to carry a bridge across the river to the Lincolnshire shore. The main line in the present application will be, approximately, 12 miles in length, and will proceed in an easterly and south-easterly direction, from a junction with the Knottingley and Swinton

Digitized by Google

Railway of the Midland and North-Eastern, east of Ackworth Station, and thence to Thorpe-in-Balne, where it will join the West Riding and Grimsby Railway (jointly owned by the Great Central and Great Northern) near Shaftholme Junction. This will give direct access from the collieries to Grimsby. The promoters also propose to take power to make a junction with the Hull and Barnsley Railway between Norton and Kirk Smeaton, thus giving access to Hull by this route, and also by the North-Eastern over the Knottingley and Swinton Railway. In its amended form the scheme is less contentious than in its original shape. The promoters of the North Lindsey Light Railway, now in course of construction, are seeking power to extend their line, this being virtually a rival scheme to the proposed Barton Light Railway.

**Yardley.**—At Tuesday's meeting of the District Council the following resolution was submitted: "That the Tramway Committee be instructed to report to the Council as soon as possible on the question of tramways from College-road, Sparkhill, to Shirley." The mover stated that in 1906 the period allowed the Birmingham and Midland Tramway Company to complete the electrification of the Stratford-road route expired, but, although the time was rapidly drawing to a close, no steps appeared to have been taken. His object in bringing the matter forward was to obtain information for the public. He had just received a letter from a Shirley resident pointing out how that district was suffering from the lack of the means of transit. Not only this, but the development of the outlying districts of Birmingham was necessary in order to deal with the slum question in the city. He had seen it urged that trams to Shirley would not pay, but there were many shopkeepers in that district whose businesses would not show any return for years to come, and the tramway company would have to look to the future also. Mr. Spires seconded the resolution, remarking that the time had now arrived to compel the tramway company to show their hand, and to declare whether they intended to lay down tramways or not. In the latter case, the Council should formulate some other scheme, and perhaps the Council itself might lay down the lines and arrange with the Birmingham Corporation to run its cars upon them. Eventually it was agreed to defer consideration of the matter until the next meeting. A letter was received from the Worcester County Council, stating that the attention of the City of Birmingham Tramways Company had been called to the granite setts laid by them in the Stratford-road, and the clerk stated that Mr. Lycett had been communicated with, and had promised to have the matter attended to. A communication has been received from the Board of Trade stating that the Board have made an order sanctioning the use of steam power on the tramway between Baker-street and College-road, Sparkhill, for a further period of 12 months.

**London County Council.**—The Highways Committee reported at last week's meeting of the Council that street widenings were being executed in connection with some of the authorised lines in West London, in consequence of which it will probably not be possible to proceed with the construction of these lines for some 12 months. The committee recommended, however, that the lines from Hammersmith Broadway to Putney should be undertaken early next year. It has been necessary to consider the question of the arrangements to be made for the erection and equipment of the car depôts, independently of the actual tramways construction, as the time occupied in acquiring sites and erecting the requisite buildings thereon is considerably longer than that required for the track. The only building required in the first instance for the tramways above referred to is a car-shed at Hammersmith, arrangements having been made for the temporary supply of energy. A site adjoining Hammersmith Broadway has been secured for the depôt, of which it is only necessary to construct part at present, but the committee propose that plans, etc., shall be prepared for the whole. The approximate cost of the car-shed is £31,000, and of the portion proposed to be first built, £21,000. The Council agreed to the committee's proposal that £300 should be voted for the preparation of plans and estimates. There are indications that an amicable arrangement will be arrived at between the City Corporation and the County Council. The Special Committee of the former body sat several times last week to consider the question from all standpoints, the object in view throughout their deliberations being to formulate, if possible, some scheme as a substitute for the veto previously decided upon. A deputation of the Highways Committee of the County Council waited upon the Special Committee, and a long and interesting conference took place, a welcome sign being the evident desire on the part of all to promote friendliness of feeling between the two bodies concerned. It is reported that the Special Committee will, with practical unanimity, present a report on June 22, recommending the Court to rescind the previous resolution. The idea in the mind of the Special Committee seems to be that the widening is desirable—not alone because of the trams, but for the purpose of accommodating the ever-increasing volume of traffic which pours over the bridge during the busy hours of the day. The widening, if their views receive acceptance, will presumably be undertaken by the Bridge House Estates Committee, and the money will be found out of the revenues of that trust.

**The Light Railways Act.**—A parliamentary paper recently issued contains a report of the proceedings of the Light Railway Commissioners and the Board of Trade in reference to light railways up to Dec. 31. Twelve out of the fifteen orders before the Board of Trade for confirmation on Dec. 31, 1903, were confirmed during 1904, the County of Hertford, Waltham Cross, and Enfield and the Dover, St. Margaret's, and Martin Hill orders being held over. During 1904 20 fresh orders were submitted to the Board by the Light Railway Commissioners, of which 14 had been confirmed. Confirmation was not refused in any case, but in that of the Southend and Colchester order powers were not granted in respect of certain proposed piers and ferries. During 1904 21 orders were confirmed, comprising 97 miles, at an estimated expenditure of £801,352. Since the commencement of the Act, in 1896, 257 orders have been confirmed by the Board of Trade, aggregating 97 miles, at an estimated outlay of no less than £11,279,780. From the date of the last report the Treasury have conditionally agreed to make a further advance of £5,700 by way of loan at 3½ per cent. in respect of the Welshpool and Llanfair Light Railway. The report of the Light Railway Commissioners states that a total of 485 applications for orders to authorise light railways (including applications for amending orders) have been made since the commencement of this Act. In respect of 278 applications (21 in the year 1904, and 257 in previous years) orders have been submitted to the Board of Trade; nine other applications, in respect of which orders are under settlement, have been approved by the Commissioners, and 176 applications have been rejected or withdrawn. The decisions with respect to four applications have been deferred, and 18 new applications, made in November last, remain to be considered. Up to Dec. 31 applications for lines on public roads, mostly electric motive power, totalled £18,058,644, of which proposals representing £5,661,643 were approved, and others representing £5,856,289 rejected, the Board of Trade dealing with applications aggregating £5,617,002. Amending orders up to the end of last year deal with lines representing £33,542,914, £13,039,261 being approved and £9,950,235 rejected, whilst proposals amounting to £12,535,340 were sent to the Board of Trade. In regard to steam lines during the same period, the schemes submitted represented some 14¼ millions, of which proposals to the amount of £6,900,000 were approved, £4,000,000 rejected, £1,453,710 withdrawn, and £6,500,000 sent to the Board of Trade. The Light Railway Commissioners have recently submitted the following orders to the Board of Trade for confirmation: Central Essex Light Railway (Amendment) Order, 1905, amending the Central Essex Light Railway Order, 1901, and Radfield and Sible Hedingham Light Railway Order, 1901 (June 6); Newark and District Light Railways Order, 1905, authorising the construction of light railways in the borough and in the rural district of Newark. The Commissioners have decided to approve the application for a light railway from Maidstone to Headcorn, subject to one or two stipulations.

## LIGHTING AND GENERAL.

**Govan.**—The extension of the electricity works in Govan-road was inaugurated last week.

**Telephone Company of Egypt.**—The register of transfers of 4½ per cent. debenture stock will be closed from 17th to 30th inst., both days inclusive.

**Walsall.**—The Electricity Committee recommend that an electric cable be laid in Buchanan-road at a cost of £194, and one in Portland-street at a cost of £60.

**Heywood.**—The consumption of electricity for April was 4,805 units as against 4,262 units for the corresponding period of last year, an increase of 543 units.

**Worcester.**—Application is to be made for sanction to borrow £6,009. 14s. 7d., overspent on the electricity capital account for machinery and equipment.

**Macclesfield.**—A scheme for lighting the town electrically has been adopted by the Town Council, and an electrical engineer is to be appointed at an early date.

**Boston.**—At a meeting of the Town Council last week a proposal to appoint an electrical engineer to prepare a scheme for installing electric light was referred back to committee.

**Paisley.**—At Wednesday's meeting of the Corporation it was stated that the total revenue to date for current supplied to the District Tramways Company amounted to £5,322. 4s. 8d.

**Hampstead.**—At the fortnightly meeting of the Borough Council the Chairman of the Lighting Committee stated, in reply to a question, that the proposal to introduce a new method of charging was still under consideration.

**Tunbridge Wells.**—It was reported at last week's meeting of the Town Council that there had been a profit in the electric lighting undertaking for the past year of nearly £1,000, which is to be applied in reduction of the rates.

**Press Telegrams.**—Press telegrams can now be accepted for transmission *via* France between the United Kingdom and Luxemburg, between the hours of 6 p.m. and 9 a.m., at the rate of 1½d. per word, with a minimum charge of 10d. per telegram.

**Darlington.**—A number of applications have been received for the installation of electric light. Messrs. Pease and Partners, Limited, it is reported, intend to introduce electric power, in the place of steam, for grinding corn at the granary in Whessoe-lane.

**Sleaford.**—The electric lighting accounts for the past year show receipts of £1,130 and expenditure amounted to £670. 2s. There has been a surplus since the commencement of the undertaking of £268, but £780 having been allotted to depreciation, there is now a deficit of some £550.

**Coventry.**—The Electricity Committee have decided to extend the mains to Rochester-road, Earlsdon, at an estimated cost of £280. It has also been decided to recommend the Council to undertake to maintain and replace consumers' electric lamps subject to a graduated scale of quarterly charges.

**Edinburgh.**—At a meeting of the Electric Lighting Committee, it was reported that the number of 8-c.p. lamps applied for from May 5 to 15 was 2,606, against 2,498 for the same period last year. The total number of applications for the year from May 15, 1904, to May 15, 1905, was 86,981.

**Islington.**—At to-night's meeting of the Borough Council the Lighting Committee will present reports from Prof. Kennedy and the borough electrical engineer upon the proposed extension of plant, with a recommendation that application be made to the London County Council for a loan of £15,500.

Digitized by Google

**Telegrams to Japan and Korea.**—The Eastern Telegraph Company notifies that on and after the 1st prox. the tariff per word for telegrams from Great Britain to Japan and Korea, forwarded *via* Eastern, will be reduced as follows: Japan, 4s. 10d.; Korea, Seoul, Fusan, and Chemulpo, 4s. 10d.; other stations, 5s. 2d.

**Fareham.**—The Urban District Council have agreed to lay an electric light cable to Upland, the estimated cost being about £90. The engineer (Mr. Blake) said it was necessary for the Council to take into consideration the question of enlarging the main in West-street, and the matter was referred to the Electric Lighting Committee.

**Southwark.**—At the meeting of the Borough Council the General Purposes Committee recommended that the Council should oppose various Bills promoted by private companies for the supply of electricity. Some members of the Council deprecated the harassing of private enterprise, but eventually the recommendation was adopted.

**Glasgow.**—It is reported that the Electricity Committee have received numerous representations regarding the charges for current, and it is not improbable that reductions will be made to shops, warehouses, etc., from 6d. per unit for 365 hours per year maximum demand and 1d. thereafter to 3½d. per unit for the first two hours' use maximum demand.

**The Decimal Association.**—This association has issued a carefully-compiled chart of the metric system of weights and measures, which has been received with approval by such scientists as Lord Kelvin and Sir Oliver Lodge as affording a popular and clear explanation of the system. The chart can be obtained from the secretary of the association, Oxford-court, Cannon street, E.C., price 1s., or mounted on linen and fitted with rollers and varnished, 5s.

**Houghton-le-Spring.**—At the meeting of the Rural District Council reference was made to recent telegraphic difficulties, and the clerk read a letter from the postal sectional engineer, in which he stated that as he understood the tramway company intended turning the current on to their lines at an early date, he would not be in a position to make arrangements to prevent interference with the telegraph line by the tramway line until he was assured that the telegraph poles could be removed to the new route suggested by the Council. It was decided that steps be taken to have the poles removed.

**Thirsk.**—The Parish Council have decided in favour of electricity for lighting purposes. At their last meeting tenders were received from the electric lighting company to light the public lamps for the season 1905-6 at a cost of 29s. 6d. per lamp, or if a three years' contract was made a reduction of 5 per cent. on this amount. The Thirsk Gas Company's tender was 31s. per lamp, or 30s. if a three years' contract was entered into. After full discussion it was decided to contract with the electric lighting company for three years. This includes the lighting of the Station-road, which has previously not been lighted.

**Batley.**—The annual report of the electricity department for the past year shows that the total revenue has been £3,764 and the expenditure £2,167, giving a gross profit of £1,597, which, after paying interest and sinking fund, leaves a deficit of £334. There are 96 consumers, the average price for current being 3·8d. per unit. Taking lighting and power together the average price is 2·6d. per unit. The opinion is expressed in the report that, considering the heavy capital expenditure (£36 068), the scattered nature of the district supplied, and the low price obtained for current, the results of the first year's working are very favourable.

**California.**—It is reported that one of the largest electrical generating companies in California was recently organised at Ukiah, with a capital of half a million dollars fully subscribed. The new company will occupy the upper part of Potter Valley as a storage reservoir, and will utilise the waters of the Eel River for generating current. It is contemplated to run a tunnel 1½ miles long through the mountains, bringing the water of the river to the head of the valley, and then give a fall of 470ft. to the dynamos. A plant of 2,500 h.p. will be installed, and this will be augmented as fast as the service lines shall have been carried to other places. It is expected that a full electrical supply can be furnished all coast towns and cities, and carried over into the interior.

**Cooper-Hewitt Mercury Vapour Lamp.**—We learn that the British Westinghouse Electric and Manufacturing Company, Limited, are now prepared to supply all types of the Cooper-Hewitt mercury vapour lamp for direct current. The efficiency of this lamp is a point of considerable value, and, in addition, the lamp possesses several important characteristics, not the least of which is its value for photographic purposes or all processes of a similar nature. Its utility in this respect is accentuated by the fact that its light is of a highly actinic quality and almost entirely devoid of red rays. As an illuminant for workshops, factories, drawing offices, etc., the Cooper-Hewitt mercury vapour lamp has demonstrated its value, especially in America, where it has been largely employed.

**Trade Notice.**—A working arrangement has just been entered into between Messrs. Ferranti Limited and Messrs. Witting, Eborall, and Co., Limited, which is of considerable interest to the electrical industry, as it affords an instance of the combination of two competitors who at one time held widely divergent views in respect to various matters connected with the design of high-pressure switchgear and the like. In the future Messrs. Ferranti's interests in India, South Africa, and (largely) on the Continent will be looked after exclusively by Messrs. Witting, Eborall, and Co., who have in addition come to an understanding with Messrs. Ferranti in respect to work in Great Britain. For instance, it will now be possible to obtain Ferranti material through any of Witting, Eborall, and Co.'s branch offices or agencies under precisely similar terms as if ordered at Hollinwood. Further, each firm will have the benefit of the other's experience, and as both firms have made a speciality of high-pressure switchgear and the like, the combination, in this respect particularly, should prove a strong one.

**Stock Exchange.**—The Stock Exchange Committee have appointed the 21st inst. as a special settling day in connection with the British Columbia Electric Railway Company's £15,000 preferred ordinary stock, representing preferred ordinary shares Nos. 83,501 to 85,000; and the 23rd inst. for the further issue of £85 000 preferred ordinary stock, representing preferred ordinary shares Nos. 65,501 to 74,000, and £90,000 deferred ordinary stock. The committee have ordered the above-mentioned shares to be quoted in the official list; also 148 500 ordinary shares of £1 each, fully paid, Nos. 160,000 to 308,500, in John I. Thornycroft and Co., Limited. Applications have been made for the appointment of special settling days in connection with the following securities: American Telephone and Telegraph Company's 25 000,000 dol. 4 per cent. collateral trust bonds of 1 000dol. each, Nos. 53,001 to 78,000; Calcutta Tramways Company's shares of £5 each (issued in 1905).

**Yarmouth.**—The income for the year ending March last amounted to £15,196. 14s. 3d., an increase of £1,313. 12s. 1d. on the previous year, and the expenditure amounted to £8,426. 14s. 3d., leaving a gross profit of £6,770. After deducting interest, sinking fund, and rebate charges there was a net profit of £1,350. 15s. 8d. The report of the electrical engineer and accountant stated that during the past four years there had been a net profit of £3,910, out of which sum £2,100 had been applied in the relief of rates, and £1,223 voted for street-lighting extensions and additions to the power station. Thus all money borrowed from the rates during the first three years, amounting to £1,893, had been fully repaid. If the committee favoured the principle of reducing the prices, they proposed the following scale of charges: lighting—offer to all consumers an optional flat rate of 5d. per unit for all units used up to 3,000 per annum, and 4d. per unit for all over and above that quantity. For power taken from lighting mains a flat rate of 2½d. per unit. The committee recommended the adoption of the report, and the Council concurred without discussion.

**Bermondsey.**—At last week's meeting of the Borough Council the Electric Lighting Committee presented their report for the year ending March 31. Loans have been obtained to a total of £98 000. The capital expenditure to date totals £105,793. The income for the year amounted to £12,015, against an expenditure of £7,711. Interest and sinking fund charges absorb £3,163. There is a payment of £500 to the reserve fund, and an additional £1,000 has been allotted to this source, as the Council's order does not authorise the creation of a depreciation fund. During the year 1,039 503 Board of Trade units were supplied, of which 282,185 were sold for public lamps, 649,914 to private consumers, and 69,939 were used on the works. The number of arc lamps was 168; arc incandescent, 336; and in side streets, 200. The total maximum demand was 538 kw. As compared with the previous year, the quantity generated is practically double, as also the quantity sold to private consumers; whilst for public lamps 82,670 units were sold beyond the supply for 1904. The report was adopted. It was resolved to give a testimonial to Mr. W. H. Vincent, the late borough electrical engineer, recording the Council's appreciation of his services.

**Belfast.**—The Corporation notify the following reductions in charges to come into force on the 1st prox.:—For lighting purposes: on the maximum demand system—an initial charge of 6d. per unit for the equivalent of 182 hours' consumption at the consumers' maximum demand per half-year (equal one hour per day), and a subsequent charge of 1¾d. per unit for all in excess of this quantity, or an alternative flat rate of 4½d. per unit. Residential lighting—a flat rate of 4d. per unit, or on the maximum demand system. The whole of the supply to any one premises must be taken at one of either rates, and all consumers have the option of being transferred from one system to the other on July 1 of any year. For power and heating, and purposes other than lighting: on the maximum-demand system—an initial charge of 2½d. per unit for the equivalent of 182 hours' consumption at the consumer's maximum demand per half-year (equal one hour per day), and a subsequent charge of 1d. per unit for all in excess of this quantity. The initial charge will be reduced to 2¼d. per unit when the consumption exceeds 2,000 units per quarter, and to 2d. per unit when the consumption exceeds 5,000 units per quarter. Special prices to consumers using current during certain hours and for stand-by purposes. The above prices are subject to a minimum charge of 20s. per annum for each meter installed.

**Beckenham.**—At the meeting of the Urban District Council the Electricity Committee submitted the following report: "The sub-committee appointed for the purpose reported that they had been in communication with the British Insulated Company and recommend the arrangement embodied in a draft letter submitted to the committee. This arrangement will entitle the Council to at once enter upon the electric light station and carry out any extension of buildings and machinery they may think proper. The consideration to be the payment of £100 to the company, who will waive their claim to a larger sum which would become payable to them under the strict terms of the contract. The Council to concede the revised price for house services claimed by the company and the company to undertake to supply cables for two years from the expiration of their contract at prices set out in the correspondence. The company to continue to work the station at their own risk until their contract expires. The committee recommend the arrangement for confirmation by the Council. The committee recommend that the consulting electrical engineer and the surveyor be instructed to prepare plans and specifications and invite tenders for extending the buildings and providing a new 250 kw. machine with the necessary boilers, etc. The extension of the power-house to provide sufficient space to accommodate machinery for the supply of the Penge tramways." The report was adopted.

**Southwick.**—At the monthly meeting of the Urban District Council a letter from the County of Durham Electrical Power Distribution Company, Limited, was read stating that the company were about to give a supply of electricity for lighting and other purposes in the urban district of Southwick-on-Wear, under powers conferred upon

Digitized by Google

them by the Sunderland Districts Electric Lighting Provisional Order, 1904, and asking for the consent of the Council to an application to be made to the Board of Trade enabling them to carry their high-tension and distribution mains overhead. The Council decided to refer the matter to the Highways Committee.

**Loughborough.**—At the meeting of the Town Council the electrical engineer reported that the cost of the recent exhibition was £44. 13s. 7d., the amount taken for admission being £25. 15s. The committee having considered the report of the electrical engineer as to the increase that would have to be made in the price per unit of electricity consumed in order to recoup the Corporation if free wiring of premises was adopted, it was resolved that the consideration of the matter be postponed *sine die*. The electrical engineer reported that he had made enquiries as to the probable demand for electricity by manufacturers and others for power purposes, but he was not yet in a position to report definitely upon the matter.

**London Gazette.**—A receiving order has been made out on debtors' petition in the estate of Alexander Holmes and Alexander McCallum, electrical engineers, Crown Works, Darwen. The first meeting in the estate of Alec. Gavan Inrig, electrical engineer, 16, Bruce-grove, Tottenham, Middlesex, will be held at 24, Railway-approach, London Bridge, S.E., on June 19 at 11.30 a.m. The first meeting in the estate of F. Shaw, electrical contractor, 258, Hessle-road, Kingston-upon-Hull, will be held at the official receiver's office, Trinity House-lane, Hull, on June 21 at 11 a.m. The last day for receiving proofs in the estate of Albert Smith, lately trading as the Electric Motor Supply Company at 54, Hounds-gate, Nottingham, is June 24.

**Telegraph Poles.**—At a meeting of the District Committee of the Lower Ward of Lanarkshire, it was stated that one of the members, when recently in London, had got Dr. Douglas, M.P., to bring before the Postmaster-General the objections of the committee to the continuance of telegraph poles and wires on the main roads in the district. The Postmaster-General replied that if the District Committee were prepared to bear the expense, amounting to about £2,000, of removing the wires from the roads to the railway line, he might arrange to have the work done. It was pointed out, however, that the committee had no power to spend public money on such work, and it was agreed to continue the pressure on the Postmaster-General to have the poles and wires removed from the public roads.

**Revocation of Patent.**—The Simplex Steel Conduit Company, Limited, having been threatened with proceedings by the Metallic Seamless Tube Company, Limited, of Birmingham, for an alleged infringement of the letters patent known as the Bayliss grip socket, and finding their business considerably impeded thereby, applied to the Attorney-General for authority to present a petition for the revocation of the said patent as the Metallic Seamless Tube Company took no steps to carry out their threat. The case was heard in the Chancery Division by Mr. Justice Ingle Joyce on the 3rd inst., when his lordship revoked the patent, and judgment was accordingly entered for the Simplex Company with costs. This decision should obviate the uncertainty which might have arisen in reference to patents connected with continuity methods for socket joint conduits.

**Dewsbury.**—The annual report of the Dewsbury borough electrical engineer (Mr. R. H. Campion) shows that during the year ended March 31 last 989,037 units of electricity were generated and 877,649 units sold, as follows: public lamps, 25 272 units; traction, 517,318 units; and private consumers, 335,059 units. The receipts amounted to £9,353. 10s. 3d., as compared with £8 814. 5s. 4d. in the preceding year, and the expenditure to £4,859. 7s. 6d., as against £4,160. 17s. 1d. in the previous year. The gross profit amounted to £4,394. 2s. 2d., as compared with £4,653 8s. 3d. After payment of interest and sinking fund there remains a net profit of £1,243. 7s. 6d., as against £1,951. 10s. 3d., a difference of £708. This is partly accounted for by a reduction in the charges for electricity and an increase in the wages bill owing to a breakdown in the cables and alterations at the station.

**Southampton.**—The Electricity Committee's report contained the following: "The Electricity Committee have for some considerable time had under their consideration a suggestion that an electrical exhibition should be held in Southampton in connection with this department. During the last few weeks several towns in the vicinity have done something in this matter, and in April the Electricity Committee visited Salisbury, where a small exhibition was being held. From information obtained there the committee are of opinion that the electricity department would benefit if an exhibition on similar lines were inaugurated in this town. The people of Southampton would then have an opportunity of seeing in operation the many uses to which electricity is adapted at the present day. The committee would like to have permission from the Council to make all arrangements for holding this exhibition at a cost to this department of £100." The Council sanctioned the proposal.

**New Atlantic Cable.**—The cable steamer "Cambria" started from Queenstown on Tuesday *en route* for Cape Canso, Nova Scotia, to take soundings across the Atlantic for the purpose of selecting the route for the new cable of the Commercial Cable Company. Soundings will be taken at intervals of about 20 miles, and this work will occupy about a month. Already the "Cambria" has successfully laid the Irish shore end of the cable for a distance of 190 miles from Waterville. Another cable steamer, the "Colonia," is to leave London with cable material and a technical staff direct for Cape Canso, whence the cable will be laid eastwards over the track that the "Cambria" will have charted until she makes the connection with the buoyed end off the coast of Ireland. The "Cambria" is a new vessel, owned by the Telegraph Construction and Maintenance Company, Limited, 370ft. in length, and 1,016 net register, specially designed and fitted with all the latest improvements for cable laying and overhauling.

**Llanelly.**—At a meeting of the Urban District Council a deputation of tradesmen was received in regard to the proposed electric lighting scheme. The leader of the deputation stated that the scheme was unnecessary, and it would add to the liabilities of the Council and increase the already heavy rates. The tradesmen did not want electric lighting, and would not take it. About a year ago an agreement between the gas company and the Council was signed, and it was hoped that it would have put an end to the dissension that had gone on for years. Scarcely had the ink on the agreement dried, however, than they found the Council giving notice to terminate it. The Chairman said the wisdom or otherwise of terminating that agreement had nothing to do with the electric lighting scheme, to which the leader of the deputation replied that it was very material, as affecting the cost of illumination in future. The Council decided, after the retirement of the deputation, to hold a special meeting to meet the tradesmen.

**Swansea.**—The financial statement in connection with the electricity works shows gross profit for the year ending March of £7,408. 1s. 5d. After allowing £103. 17s. 10d. for defective meters, bad debts, etc., £3,381. 19s. 2d. interest, and £2,651 for sinking fund, the net profit is £1,271. 8s. 5d. This, with the balance £744. 11s. brought forward from last year, amounts to £2,015. 19s. 5d., but inasmuch as £3,125. 18s. 9d. has to be put aside for sinking fund, in accordance with the requirements of the Local Government Board, so as to bring this fund up to date, there is a deficit of £1,109. 19s. 4d. In submitting his annual report, the electrical engineer (Mr. C. A. L. Prasmann) stated that the gross cost of coal and cartage of ashes was £1,279, a decrease of 24 per cent. Swansea was better by over 50 per cent. on the average than other provincial stations. "Wages on generation" came to £1,395. 13s. 2d. gross, a decrease of 14 per cent. The total costs this year (£6,983. 12s. 3d. gross) represent a decrease over last year of 7¼ per cent. The average price for private lighting had been reduced by about 10 per cent. From April 1 certain reductions to private consumers came into force for both lighting and power. The revenue was £13,307, and the costs of the station £6,003. It is expected that during the ensuing year private consumers for both lighting and power will be materially increased, in addition to which the Corporation tramways will be a large customer with very little increase in the capital expenditure.

**Barrow.**—From the annual statement of accounts it appears that the total capital expended on electricity works is now £92,655. The revenue this year was £11,623, having increased from £9,248 over the previous year, or an increase of £2,375. The expenditure during the year was £4,924, against £4,574, an increase of £350. The profit was £6,698, an increase of £2,025. The interest and sinking fund charges have risen from £4,195 to £5,499. After paying all charges there is a net profit on the year of £1,198. The loss the first year was £705, second year £961, and third year £341. In the fourth year a profit of £425 was made, and last year a profit of £478. The number of lamps connected showed an increase of 5,626; the figure this year being 50,508, against 44,882 last year. The number of units sold increased from 540,146 last year to 837,454 this year, an increase of 297,308. The cost of production per unit for the past year was brought down to 1·41. Adding interest and sinking fund (1·57d.) the total cost per unit was therefore 2·98d. The one feature which was unsatisfactory was the large amount of capital that had to be expended. If the department had been able to have the same length of period for the repayment of loans as for the gasworks, the net profit would have been £2,400, instead of £1,198. The chairman of the Electricity Committee and the electrical engineer have been authorised to attend the convention of the Incorporated Municipal Electrical Association at Edinburgh. The electrical engineer has been instructed to fix a price, subject to the approval of the committee, for the lighting of the street lamps at Vickerstown during the same hours as the lamps in the town.

**Nottingham.**—At the meeting of the City Council a petition placed before Parliament by the Manchester Corporation against the agreement between the Postmaster-General and the National Telephone Company was considered. The petition contends that the agreement will mean that it will be to the interest of the Postmaster-General not to grant licenses relative to the working and use of telegraphic and telephonic communication, and therefore tends to destroy competition between the two telephone systems, and to continue, if not to increase, the present excessive charges made. The memorial was referred to a joint meeting of the Parliamentary and General Purposes Committee. The electrical engineer reported that the distributing mains have been extended in 43 directions during the year, the total extensions being 2·41 miles. The mileage of the distributing mains at the end of the year was 49·81. In addition to the extension of the distributing mains three new feeders have been laid from the generating station in Talbot-street. The total mileage of feeder cables laid during the year was 4·9. The number of applications received for a supply of electricity on March 31 was 2,793, as compared with 2,557 on March 31, 1904. The number of 8-c.p. lamps or their equivalent connected up to the mains on March 31 was 267,401, as compared with 239,366 at the end of March, 1904. Seventy-six additional motors have been connected up during the year, representing 238 increased horse-power. The total power connected to the mains was 2,014 h.p., as against 1,776 at the end of March, 1904. The number of units sold during the year for various purposes was as follows: for lighting purposes, 3,431,964; for power purposes, 1,142,636; for tramway traction, 3,895,321—total, 8,469,921; 47·65 per cent. of the units sold for private lighting were at the reduced rate of 1½d. per unit. The total number of units sold for all purposes during the year ending March 31, 1904, was 8,101,810. The annual report was adopted. The spare set dynamo for the Easterofe destructor was erected in May of last year, increasing the available horse-power from 13,605 to 13,810. A strong demand for lighting and power still continues, and the Corporation have obtained sanction to a loan of £100,000 for extensions. This amount will be raised from time to time as occasion requires. During the past year the whole of the plant was maintained in good condition out of revenue.

**Worthing.**—At the meeting of the Town Council, the members had before them an important report from the resident engineer (Mr. Geo. Porter) with reference to the extensions of plant and machinery, etc., which Mr. Porter considers will be essential to meet the demands of the near future. Mr. Porter pointed out that the three existing boilers will all be working together in the winter 1905-6, so that there will be no spare boiler available for use when any one of the others is opened up for cleaning or repairs. A new boiler with steam and water pipes must therefore be obtained before the heavy winter's works sets in. The foundations and part of the setting of the boiler were built when the plant was last extended, so that very little structural work will be entailed. During the past winter the engines in use were one of 400 h.p. and one of 160 h.p., two engines of 160 h.p. each being in reserve. The anticipated increase will require the use of the two reserve engines, and at the present rate of expansion of business an additional engine and dynamo will be required for the winter 1906-7. Mr. Porter accordingly recommended that an additional engine be obtained large enough to supply about 10,000 lamps on at one time. At the present charges for current (6d. per unit) this engine would probably be sufficient for the requirements of the winters 1906-7-8-9; but if the price of current be reduced, it was probable that an additional 20,000 lamps may be added in two years from the date of such reduction. For this proposed engine (about 600 h.p.) no additional buildings will be required, but a new condensing plant will be necessary, as the existing one will be taxed to its utmost capacity in the coming winter of 1905-6, and an additional boiler and feed pump will also be required. The cost of the additional boiler required for the next winter Mr. Porter puts at £860, and that of the extensions next year at £4,700. It will also be necessary to lay two new feeder cables this summer, as the three original feeders are very much over-loaded. The three existing feeder cables were put down to carry current to the distributing mains equivalent to about 9,000 8-c.p. lamps, but during last winter these feeders carried current equivalent to a load of 15,000 8 c.p. lamps in use together. To enable them to carry the additional current, the pressure at the generating station was increased beyond the normal. The estimated cost of the new feeders required at once Mr. Porter estimates at £1 287, and he also recommended the provision of a farther sum of £653 for consumers' connections, meters, etc., and £200 for distributing mains extensions. The Council decided to substitute £600 for the £200 recommended for distributing main extensions, and subject to that alteration the whole of Mr. Porter's recommendations were approved.

**Morley.**—At the meeting of the Town Council the electrical engineer (Mr. J. E. Ellis) reported that the output from the electricity works during the month ending April 30 was 9,587 units, against 10,089 for the same period last year, and that the actual units sold to consumers by meter was 6,296 against 4,573, being a decrease of 502 in units sold. There had, however, been an increase of 1,723 units sold to private consumers. Mr. Ellis also submitted his report of the working and financial results of the electric lighting undertaking for the year ending March 31, in which he said: "I regret to report that from a financial point of view we have not been quite so successful as the year previous. The following are details of the working for 1904-5 and 1903-4 respectively; total number of units generated, 199,427—202,840; total sold, 142,959—142,958; amount used in works, 13,238—14,532; magnetising units, free supply, and testing purposes, 43 230—45,550; units sold to private consumers, 95,217—96,834; motors, 742—714; arc lamps and side lights, 47,000—46,124. There are 32 more consumers than in the previous year, but the units sold are 875 less, besides which the ½d. reduction in price represents some £200." Mr. Ellis proceeds: "You will readily see that, had we not reduced the price last year ½d. per unit, our revenue would have been about £25 more than the year previous, notwithstanding the output practically remaining the same. The only explanation I can offer for the output remaining constant is—firstly, prejudice against the electric department; secondly, the tradespeople do not realise the advantages of the electric light; thirdly, remarks made in the Council-chamber in the past have not been of a consolidating nature to encourage the public to take a supply of electricity, but happily a better feeling appears to be coming on the horizon; and, lastly, a fit of all-round economy appears to be passing over the district. . . . Distribution is somewhat higher owing to the unfortunate burn-out of three converters which broke down in the town hall sub-station, which cost about £100, and is included in this item. Public lamps are a little higher owing to a portion of the costs of the new arc lamps being paid for out of revenue, and which is included in this item. Salaries of engineers are a little higher owing to the amount of new work on outside not being so plentiful as the year previous, notwithstanding the unfortunate breakdown, Messrs. Pollit and Wigzel repairs to plant and portion of arc lamp account being paid out of revenue, the total of which amounts to about £150. Our total expenditure is only some £7 more than the year previous. Our interest and sinking fund is £1,846. 1s. 7d., as against £1,789. 3s. 11d., being an increase of £56. 17s. 8d. The gross profit for the year is, before providing for interest and sinking fund, £605, equal to pay 2¼ per cent. on the total capital expenditure." After some little discussion, the report was adopted by a large majority.

## PROVISIONAL PATENTS, 1905.

JUNE 5.

**11756. Improvements in or relating to apparatus for preventing the "live" wires of electric tramways falling to the ground in case of breakage.** Samuel Sims and Alfred Roberts, 8, Quality-court, Chancery-lane, London.

**11745. Improvements in electric telegraphy.** Isidor Kitsee, 18, Fulham-place, Paddington, London. (Complete specification.)

**11770. An improved method of and means by which electrical bells may be employed on high-tension circuits.** Francesco Agaggio, 70, Chancery-lane, London. (Complete specification.)

**11773. Improvements in magneto-electric ignition apparatus.** Frederick Richard Simms and Robert Bosch, 4, South street, Finsbury, London. (Complete specification.)

**11774 Improvements in electric fuses and cut-outs.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

JUNE 6.

**11805. Improvements in switches for use for electric lighting and power.** William Cecil Kirwan and Kyran Quaney, 11, Brookfield-terrace, Donnybrook, Dublin.

**11813. An improved universally adjustable electric light bracket.** Edward James Overell, 62, Beacon Hill-road, Newark-on-Trent, Notts.

**11821. Load equaliser for alternating currents with automatic regulation.** Rudolf Braun, 68, Seymour-grove, Old Trafford, Manchester.

**11840. Electric block signalling and train-control system.** John Alexander Whyte, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**11860. Improvements in or relating to electric target setting apparatus.** Alfred Julius Boult, 111, Hatton-garden, London. (Phönix Elektrotechnische Ges. m. b. H., Germany.) (Complete specification.)

**11861. Improvements in battery plates.** Harry Cross Hubbell, 111, Hatton-garden, London. (Complete specification.)

**11862. Improvements in battery plates.** Harry Cross Hubbell, 111, Hatton-garden, London. (Complete specification.)

**11881. Improvements in arc lamps.** Bernard Mervyn Drake and John Marshall Gorham, 66, Victoria-street, Westminster, London.

JUNE 7.

**11899. Improvements in electrical relays for railway track circuits and telegraph purposes.** William Robert Sykes, jun., Wyndcott, Birchwood Park-avenue, Swanley, Kent.

**11901 Electrically operating stop-watches from more than one place automatically.** Basil Alexander Pilkington, 12, Atholl-place, Edinburgh.

**11921. Improvements in methods and apparatus for producing electric sound signals.** Charles Henry O'Brien, 5, Corporation-street, Birmingham. (Complete specification.)

**11923. Improved controlling apparatus for electrically propelled vehicles.** Willis Nelson Stewart, 45, Lansdowne-road, Clapham, London.

**11924. Improvements in driving gear for electrically-propelled vehicles.** Willis Nelson Stewart, 45, Lansdowne-road, Clapham, London.

**11931. Arrangement for suppressing harmonics in alternating-current machines.** La Société Anonyme Westinghouse and Maurice Leblanc, Westinghouse Patent Bureau, Westinghouse Building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, June 10, 1904, being date of application in France.) (Complete specification.)

**11949. Improvements in and relating to the manufacture of incandescent filaments for electric incandescent lamps.** Alexander Just, Franz Hanaman, and Vereinigte Elektricitäts Act.-Ges., 7, Southampton-buildings, Chancery-lane, London.

**11967. Improvements in connection with hoisting gear for arc lamps and other like purposes.** Crompton and Co., Limited, and Ernest William Abbott, 18, Southampton-buildings, Chancery-lane, London.

**11970. Improvements in and relating to electric switches.** The British Thomson-Houston Company, Limited, and Edmund Basil Wedmore, 83, Cannon-street, London.

**11971. Improvements in vapour electric apparatus.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

JUNE 8.

**11995. Armoured casing for electrical wiring and the like.** Louis Howell, 10, Victoria-road, Swindon.

**12023. Electric conductor rail insulator.** Charles Harold Roberts, Ashurst, Pinner-road, Harrow-on-the-Hill, Middlesex.

**12024. An improved electrical switch.** Andrew Wybrant Penrose, 28, New Bridge-street, London.

JUNE 9.

**12061. Improvements in methods and apparatus for producing and utilising electricity and steam power.** Henry Ernest Fry, 24, John-street, Bedford-row, London.

**12062. Improvements in connection with regulating rheostats and motor starters for electrical purposes.** George Elwin Fletcher, 17, St. Ann's-square, Manchester. (Complete specification.)

**12090. Improvements in electrical measuring instruments.** George Keith Buller Elphinstone, Century Works, Lewisham, London.

Digitized by Google

**12697. Improvements in and relating to electric arc lamps.** Benjamin Zusman, 18, Southampton-buildings, Chancery-lane, London. (Oskar Könitzer, Germany.)

**12166. Improvements connected with electric tail lamps for motorcars.** George James Jackson, 15, Water-street, Liverpool.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published June 29.*

1904.

**13015. Electric telegraphy.** Brown.

**13051. Dynamo-electric machines.** Walker.

**13084. Electric incandescence vapour lamps.** Butler-Burke.

**13274. Means for controlling the trolleys of electrically-propelled vehicles.** Little.

**13276. Protective devices for electric generating and distribution systems and apparatus.** British Thomson-Houston Company, Limited. (General Electric Company.)

**13370. Casing for protecting electric leads.** Siemens Bros and Co., Limited, and Kerse.

**13709. Automatic electrical signalling apparatus for railways.** Algernon Hamo Binyon and Robert Percy Brousson.

**13736A. Apparatus suitable for detecting electrical oscillations.** Fleming. (Date applied for under Patents Rule 9, June 17, 1904.)

**13984. Electric fuses.** Pinkerton.

**14197. Methods of making electric armature coils and other hollow articles.** British Thomson Houston Company, Limited. (General Electric Company.)

**14792. Electric railways on the surface-contact system.** Rothwell.

**14879. Apparatus for controlling the lighting and extinguishing of gas, the flow of fluids, or the actuation of electric switches, and for analogous uses at predetermined times.** Harris.

**15069. Electric switches, especially applicable to fluid-pressure governers.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15364. Electric controllers.** British Thomson-Houston Company, Limited. (General Electric Company.)

**15626. Dynamo-electric machines.** Sayers and Mavor and Coulson, Limited.

**15872. Arc lamps.** Viarmé.

**16662. Electric motor control systems.** British Thomson Houston Company, Limited. (General Electric Company.)

**16764. Electric switches.** Johnson. (Voigt und Haeffner Akt.-Ges.)

**17020. Emergency devices for railway vehicle and like brake and controlling systems.** British Thomson-Houston Company, Limited. (General Electric Company.)

**17101. Emergency brake control systems.** British Thomson-Houston Company, Limited. (General Electric Company.)

**17176. Electric vapour arc lamps.** Peritz.

**17287. Trolley pulleys for electric railways, tramways, and the like.** Welsh.

**17375. Terminal for electric cables.** Sardy.

1905.

**700. Electric transformers.** Heinicke.

**1589. Electric train-lighting systems.** Union Elektricitäts-Ges. (Date applied for under International Convention, Jan. 27, 1904.)

**2187. Safety lock with an electric warning device and detonator.** Audibert.

**2313. Electric furnaces.** Bosworth.

**4716. Telephone exchanges.** Lundquist.

**4786. Arc lamp.** Hearson. (Phönix Elektrotechnische G. m. b. H.)

**6838. Suspension of overhead conductors for electrically-operated railways and the like.** Jones. (Date applied for under International Convention, April 2, 1904.)

**8711. Distribution of electric energy to apparatus capable of being operated by direct and also by alternating currents.** Lamme. (Date applied for under International Convention, May 3, 1904.)

## NOTES.

**S.B.E.**—The June number of the Belgian Society of Electricians (Société Belge d'Electriciens) contains the proceedings of the last annual general meeting and papers by Monsieur Léon Versé on various methods indicating the poles, and by Maurice Leblang on the Cooper-Hewitt electric lamp.

**Economy in Firing.**—We have received No. 9 of the Library of the Mois Scientifique et Industriel, which has already reached its fourth thousand. It is entitled "L'Economie dans la Chaufferie," and is edited by J. Izart. An interview with Mr. Booth on the subject is appended. The various types of boilers and stokers now in use are treated and illustrated, and the whole system is threshed out in all its details.

**Radium and Therapeutics.**—Radium has been widely mentioned as a panacea for cancer, and eminent scientists are still hopeful that it may prove a valuable remedial agency, but so far the cures have been of an isolated character. It is reported, however, that a distinguished surgeon, lately the X-ray specialist at a large West-end hospital, is conducting experiments in conjunction with Sir William Ramsay with a view to evolving a new form of treatment.

**The Institution.**—The annual conversazione will be held, by permission of the Trustees, at the Natural History Museum, Cromwell-road, Kensington, on Thursday, the 29th inst., from 9 to 11.30 p.m. Visitors will be received by the President and Mrs. Siemens, and the President-Elect and Mrs. Gavey. Those travelling by railway to or from the museum will be allowed the free use of the District Company's subway, which leads from South Kensington Station direct into the south-east corner of the grounds of the museum.

**New York Lighting.**—The Governor of New York State has endorsed the lighting investigation committee's Bills fixing the price of gas and electricity in New York City. These fix the price of electric light furnished to private consumers at 5d. per kilowatt-hour, except that a rather higher rate may be charged in certain districts. The price for electric street lamps consuming 450 watts is fixed at £20 per annum, £18 for lamps consuming 325 watts, and £13 per lamp where two lamps are attached to a single pole.

**Radium.**—It is reported that Dr. Tizzoni, a professor at Bologna University, has presented to the Scientific Academy of that town the results of his experiments in the cure of hydrophobia by the radium rays. He injected several rabbits with violent hydrophobia virus, and then submitted them to radium rays. All the animals recovered within six days, including those whose treatment did not begin until the malady was at its climax. It is stated that experiments are likely to be made on human beings suffering from hydrophobia.

**Wireless Telegraphy.**—It is reported that the Admiralty have definitely fixed upon Marsden as the site of a new Marconi wireless telegraph station. A similar intimation was made to this effect some time ago, but it was afterwards announced that the decision had been cancelled. As a matter of fact, the Admiralty surveyors have been engaged in viewing other situations, and measurements were taken at Tynemouth. The position at Marsden, however, was found to be more suitable, the cliff top where the Marsden sub-division of the South Shields Coastguard Station is located being the highest and most prominent part of the coast between the Tyne and Wear. A commencement with the station will, it is stated, be made almost immediately. The position is between Marsden Hall and the cliff top, which is 50ft. above high-water level. It is stated that although intended primarily for naval purposes, the station will be extensively employed commercially.

**A.E.I.**—The *Proceedings* of the Italian Institution of Electrical Engineers (Associazione Elettrotecnica Italiana), vol. ix., Part 2, contain, besides the usual institution notices, etc., papers on "Electric Traction with Monophase Motors," by U. Segre, of Naples; "Monophase Motors in the U.S.A.," by E. Soleri, of Turin; "Various Electrical Measurement Instruments," by V. Arcioni, of Milan; "Coherers," by U. Crudelli, of Rome; two articles on the "Osmium Lamp," by G. Revessi, of Rome; an essay on the "Hydro-Electrical Plant of the Turin Municipality," by E. Silvano, of Turin; and an article on "Modern Incandescent Lamps," by Prof. P. Montù, of Naples. All these papers are, as usual, well supplied with illustrations and diagrams.

**Parcels Traffic.**—From the report for the past year of Mr. P. J. Pringle, manager of the Burton Corporation tramways, it appears that the parcels delivery system inaugurated last November has, contrary to expectation, met with scanty support so far, though the revenue from passengers' luggage and newspapers shows a satisfactory increase, the total number of parcels of all classes amounting to nearly 40,000. Over 600 parcels have been dealt with in a day. The traffic from the parcels delivery system is gradually increasing, and Mr. Pringle's prediction that a considerable improvement will occur when its advantages are better known has a good chance of being realised, excellent results having been attained in other towns where the system has been introduced.

**New Single-Phase Railway.**—The French Westinghouse Company, we learn, have recently secured the contract for the installation of the Westinghouse single-phase railway system on the Bergama, Valle Brembana Railway, Italy. This is the second single-phase railway contract secured by the French Westinghouse Company in that country, the first being the Rome-Civita-Castellana Railway. The preliminary details of this line are as follows: The length of the line is some 19 miles, and it will be served by five 30-ton locomotives equipped with four 75-h.p. Westinghouse single-phase motors, multiple-unit control, and pneumatically-operated bow trolleys. The gauge of the track will be 1·44m. The power station is to be situated about 1 km. out of Valle Brembana, and will be equipped with three single-phase 500-kw. Westinghouse alternators running at a speed of 500 revolutions per minute. These will generate a voltage of 6,000, at which pressure current will be delivered direct to the line.

**Electric Tramways and Football.**—In the days of the horse tram the winter pastime was looked upon as a valuable factor in increasing the revenue of tramway systems, but with electric traction the extra traffic is not an unmixed blessing. The report for the past year of Mr. S. J. Watson, engineer and manager of the Bury Corporation electricity works, furnishes a case in point. The normal maximum tramway load did not exceed 472 kw.; when a match was on it reached 715 kw., the extra generating plant increasing the fund for interest and sinking fund by £675 per annum. This amount, divided by the extra units used by football cars, which may be taken at about 4,750 units per annum, gives a cost of 2s. 10d. per unit for running this service, and spread over the annual consumption of 9,000 units means that an additional charge of ·18d. per unit has to be included in the price paid by the tramways department for current. If these excessive loads did not obtain, a further reduction of nearly ¼d. per unit would be practicable. Would there not

Digitized by Google

be a chance of utilising the additional plant in mid-week by offering special terms to large power consumers?

**New Publications.**—The *Journal* of the Franklin Institute, Philadelphia, contains articles on "The Testing of Cast Iron," by Dr. R. Moldenke; "The Mississippi: Controlling Floods, Navigation Improvements," by Mr. H. Van Meerten; and "The Determination of Sulphur in Iron Ores," by Mr. J. H. Graham. The *Electric Journal*, Pittsburg, U.S.A., is the successor of the *Electric Club Journal*. It is now taking a wider range, having extended its field considerably. The issue for June contains articles on "Transformer Insulation: Relation of Ohmic Resistance and Dielectric Strength, by Mr. O. B. Moore; "Armature Windings of Alternators—Open-Type Windings," by Mr. F. D. Newbury; "Experiences on the Road," by Mr. B. C. Shipman; "A 135-ton Single-Phase Locomotive," by Mr. N. W. Storer; "How to Calculate Regulation," by Mr. J. S. Peck; "Static Disturbances in Transformers," by Mr. S. M. Kurtner; "Durability of Steam-Turbine Vanes," by Mr. J. R. Bibbins; "Protective Apparatus," by Mr. N. J. Neall; "Modern Practice in Switchboard Design" (continued), by Mr. H. W. Peck; and "Factory Testing of Electrical Machinery" (continued), by Mr. R. E. Workman.

**Radium.**—The results of his researches into the origin of radium are described by Mr. Bertram B. Boltwood in an article of which an abstract appears in the *Journal* of the Chemical Society. The author extended the general method of investigation previously employed to 22 different samples, comprising 12 distinct mineral species, and he found, in harmony with the earlier work, that the quantities of uranium and radium occurring together are directly proportional; hence, he states, the only possible conclusion is that uranium is the parent of radium. The participation of thorium in the production of radium is excluded by the fact that the radium-uranium ratio is independent of the percentage of thorium in the minerals. It is highly probable, as suggested by Rutherford, that intermediate stages exist between the uranium atom and the radium atom. The persistent appearance of lead as a constituent of uranium-radium minerals may indicate that this element is one of the final disintegration products of uranium. The only mineral examined by the author which was found practically free from lead was a sample of uranophane from North Carolina. This is geologically the youngest of the minerals examined, and it would naturally contain very little lead if this element was a final disintegration product. The author's experiments show that monazite from various sources contains 0·3 to 0·4 per cent. of uranium. The presence of notable quantities of uranium and radium in monazite explains the accumulation of helium in this mineral, for monazite is geologically very old, and the production of helium through radium from uranium has doubtless been going on for countless ages.

**Municipalisation in America.**—The outspoken utterances of Glasgow's tramway manager, Mr. James Dalrymple, now on a visit to the States, appear to have created a fluttering in the municipal dovecots of the Great Republic. Mr. Dalrymple is reported to have come to the conclusion that in America municipal ownership could not be completely successful on account of the way in which politics dominate the situation. This is certainly a factor to be reckoned with, for across the Atlantic politics enter into the methods of the community in quite a remarkable degree. When a Presidential election approaches, almost everybody deems it his business to "run on the ticket" of one or other of the candidates. So far as it has been tried, municipal trading has not proved a great success in the States, and it is not difficult to realise that under such administrations as the Tammany *régime* it would be highly undesirable. To judge by reports, however, the municipalities have been largely purged of this element during President Roosevelt's period of office. Mr. Dalrymple is stated to hold that the only antidote to political influence in municipal matters is to be found in a complete Civil Service system, while he is also credited with the opinion that "municipal ownership must be divorced from politics," with which most people will agree. Apart from this, he does not view the economic conditions of the big American as conducive to municipal success. Meantime, it is interesting to note that the advocates of municipal trams for Chicago, at whose invitation Mr. Dalrymple went to America, are much perturbed at his candour, and are seeking to explain his criticisms by stating that the opponents of the scheme have grossly misrepresented matters to him.

**The Embankment Scheme.**—When the committee of the House of Commons, in sanctioning the London County Council's embankment scheme, inserted a stipulation as to the widening of Blackfriars Bridge, it was feared by many that this proviso would amount to a continuation of the veto previously imposed upon the measure, especially as the City Corporation were still unrelenting. Representatives from Spring-gardens have interviewed the authorities at the Guildhall, however, and apparently to some purpose, as it is now announced that the special committee of the Corporation to whom, in conjunction with the Bridge House Estates and the Streets Committee, the matter was referred, have decided to recommend the Corporation to give their support to the scheme. The method of widening and the conditions under which tramways shall be admitted into the City remain for further discussion. The report was expected to come before the Corporation this week, when there is likely to be a spirited debate, as a section of the City Fathers are apparently irreconcilably opposed to the introduction of the trams within their domains. Assuming the Bill survives this ordeal, as it not improbably will, having regard to the considerable change that has taken place in the attitude of the Corporation as a whole, and that no prohibitive conditions are imposed, it has still to run the gauntlet of a third reading in the House of Commons and consideration by the Upper Chamber. It is scarcely likely now to be thrown out by the Commons when it is discussed "on the floor of the House," and if the measure succeeds in negotiating what is practically the final hurdle—the Lords—the much-talked-of scheme will presumably, for better or for worse, crystallise into an accomplished fact.

**An Electrical Aerial Ferry.**—There has just been completed at Duluth, U.S.A., an electrically-operated aerial ferry, the first structure of its kind in that country. A canal was constructed at Minnesota Point some four years ago, and communication was maintained between the banks by an ordinary ferry, which after a time was supplanted by a steam ferry. The latter proving expensive, it has in its turn been superseded by the contrivance referred to above, which is now in operation. The canal is 300ft. in width, and a steel bridge has been erected across it at an altitude of about 180ft. above the level of the water to permit of vessels passing through without lowering the masts. The car is suspended from the bridge by hangers, and the friction of all the working machinery is reduced to a minimum by the use of roller bearings. There are two 50-h.p. electric motors located under the floors of the car. These operate two drums, on which are wound 1in. cables, extending to the truss and thence to the tower, where they are fastened, thus producing the motion which causes the car to travel. The car has a normal speed of about four miles per hour, but the equipment is capable of propelling it at twice that

Digitized by Google

speed, and the passage can be made in little more than a minute. The cost of the ferry totals between £20,000 and £25,000, and it is estimated that, including the interest on capital expenditure payable by the City Council to the State, it can be operated at a cost not exceeding £1,500 per annum, representing a saving of one-third of the cost of the steamboat ferry. The platform of the car measures 50ft. by 34ft., and contains two neatly-finished compartments, in addition to space for wagons or street cars, the total capacity being some 65 tons.

**Development at Niagara.**—From the current number of the *Canadian Engineer*, we observe that excellent progress is being made with the construction of the three great works on the Dominion side of the Falls. At the Ontario Power Company's works, work on the power-house distributing station and tunnel was carried on all the winter. The foundations for the intake piers have been laid, and preparations are being made to let the water into the fore-bays this month. The gate, which is of the "Stoney" type, is already in position. The power-house will have temporary ends put in to enclose the units as they are installed. It is expected that the works will be in operation by August. Good progress is also being made with the plant of the Electrical Development Company. The civil engineering works are practically completed, and the erection of the power-house is being proceeded with. The transformer station is well advanced, and the electrical and hydraulic machinery will shortly be installed. It is probable that the first unit of 12,500 h.p. will be ready to transmit current in the autumn. The Canadian Niagara Power Company's works are rapidly approaching completion in regard to the units it at present has in contemplation. The power-house will be finished next month. Three wheels of 10,000 h.p. each are already erected and in working order, one of them being connected up to the United States side of the river for use in case of accident to the big power works there, with which the Canadian Company is financially associated. Two more wheels are being installed, and will be completed during the summer. The 60,000-volt switches are nearly finished, and the low-tension 'bus-bar compartment is completed. The transformers are all in place. The contract has been let for the second section of the wheel-pit, and the work of excavation will be finished in about nine months. This section will contain six units of 10,000 h.p. each.

**Cast-Iron Magnets.**—Mr. B. O. Peirce presented recently to the American Academy of Arts and Sciences a useful contribution on the properties of magnets made from hardened cast iron. The work from which the data given in the paper were obtained was done in the Jefferson Physical Laboratory of Harvard University. The object of the experiment was to ascertain how far hardened cast-iron magnets could be used to replace steel permanent magnets in moving-coil galvanometers and other instruments requiring permanent magnet control. Mr. Peirce found from early experiments with iron castings that as they come from the foundry they make most unsatisfactory magnets as far as permanence is concerned. On the other hand, these magnets, if properly hardened and aged after being machined, compare favourably in strength, in permanence, and in the relatively small changes of their moments with room temperature, with the best of tool steel magnets, even if in strength, though not in their other qualities, they fall a little behind magnets made, in a forming press, of steel specially prepared for the purpose. It is in the hardening of the cast iron that the secret of success appears to lie, and the author points out that the castings must be raised to a very high temperature before being chilled. The temperature used for hardening steel is much too low to produce the results required with cast iron. If the casting is heated to a very bright red and then plunged into the bath, the outside may become hard to the file, while the interior, as magnetic tests clearly show, remains soft. In this case, however, the material will stand a higher temperature without injury, and if the mass be reheated, and when it is just below the melting point be suddenly chilled, the whole interior becomes hard. A number of experiments are then described with various forms of magnets, and curves are given by which the field of the cast-iron magnet when soft and when hardened can be compared with that of steel magnets of the same form. The curves clearly support the author's contention that satisfactory cast-iron magnets can be produced. For certain forms of instruments where the shapes of the magnets are such that they cannot be easily formed out of steel, cast-iron magnets can be successfully used and possess many commercial advantages.

**Turbine Vanes.**—An interesting article on the durability of steam-turbine vanes is contributed to the *Electric Journal* (Pittsburg, U.S.A.) by Mr. J. R. Bibbins. At the commencement the author refers to a report upon a life-test of a German-built Parsons turbine, of which the vanes and all interior parts, as well as the bearings, were stated to have shown not the slightest sign of wear after running 17,200 hours—practically day and night for two years. A British engineer who had been in charge of the same turbine station for eight years stated that during this period no wear was observed on the interior of the turbines. Two years later they were again opened for his inspection, when, to quote his own statement, "they were in as good a state as when they left the builders' works." The author then describes the results obtained at the turbine plant of the Westinghouse Air Brake Company. The first machine of 400 kw. was installed in August, 1899, and the plant has since been in continuous operation on the regular factory light and power load. This machine was opened in March of the present year. In order to show clearly the condition of the vanes, two sample blades were deliberately broken out of the eighth and twelfth rows respectively of the low-pressure rotor barrel. Here the greatest quantity of moisture occurs in the expansion of steam, and here wear from steam erosion would, if at all, be expected. Three facts are apparent from these exhibits: first, that the old vanes have retained their full cross-section, and consequently their full mechanical strength; second, the vane angles are unimpaired, and hence their efficiency is permanent; third, the working steam surfaces have not lost their original smoothness. The author remarks that the secret of the long life of vanes in the Parsons type of turbine lies in the low steam velocities employed. This desideratum is secured by utilising the principle of compounding. Instead of one expansion stage, there are 58 in this size of turbine. In each the energy of velocity is abstracted by the moving vanes as fast as it is generated, so that the steam velocities throughout the turbine range no higher than 150ft. to 600ft. per second, although the same result is accomplished as in the single-stage turbine, where a velocity of 4,000ft. per second may obtain. The excellence of the results obtained with the above-mentioned turbine is emphasised by the fact that the steam supply has been excessively wet.

**Canadian Telephone Enquiry.**—We have received further reports of the proceedings before the committee appointed to enquire into the telephone systems of the Dominion, bringing matters down to the 26th ult. Chief interest to our readers will centre in the views expressed by Mr. Herbert Laws Webb, who was examined at great length. Mr. Webb's views on municipal telephony are

Digitized by Google

tolerably familiar to our readers, and it will be unnecessary to follow his remarks in detail, but there are a few points in this connection which are worthy of reproduction. The result of municipal telephony in England, he said, might be summed up by saying that it had wasted a great deal of money. All these systems were equipped with entirely obsolete plants, and were laid out quite wrongly from an engineering point of view. The net result of the five municipal systems in operation was that they had spent about half a million in serving 10,000 users not already served by the National Telephone Company. He differed on many points from Councillor J. Willock, chairman of the Glasgow Electricity Committee, whose evidence we referred to in our issue of the 26th ult., and stated that many of the figures given by the latter were inaccurate. He likewise held that the State telegraphic and telephonic system had been more or less a failure in England. Telephonic development had been greatly hindered in this and most of the Continental countries by legislative restrictions. The greatest progress had been shown by Norway and Sweden, which were comparatively free from State intervention. In further examination Mr. Webb stated that he did not condemn municipal telephony in principle, but that the great error on the part of the municipalities owning telephonic systems in Great Britain had been the selection of obsolete plant after they had had the accumulated experience of other telephone systems to judge by. Although the charges in Great Britain for trunk calls were only half those of the United States or Canada, he did not think they were nearly so satisfactory, as the facilities were much inferior, and there were frequently delays in obtaining communication over long distances. He deprecated the practice in England of limiting conversations over trunk lines to six minutes as being frequently quite inadequate, and contended that such restrictive regulations would not be permitted in the case of a private company.

**An Electro-Hydraulic Elevator Plant.**—An interesting description appears in the *Electrical Review* of a modern hydraulic elevator plant at a goods store in Kansas City, which is operated by three Worthington three-stage motor-driven turbine pumps. The power plant of the store contains three generators—two of 75 kw. and one of 160 kw., each direct connected to a tandem compound high-speed engine. These generating units supply power to motors for various services in the building. Power is distributed for electrically operating feed pumps, elevator pumps, a ventilating fan, an ice machine, circulating pumps, and other apparatus. A notable feature of this plant is a battery of three high-pressure turbine pumps. Two machines, each of 300 gallons per minute capacity, are driven by 45-h.p 220-volt motors. The third pump has a capacity of 500 gallons per minute, and is driven by a 220-volt motor of 70 h.p. These machines maintain a pressure of 140lb. in the system. Their motors are controlled by standard Cutler-Hammer automatic controlling apparatus, which is mounted on panels and assembled uniformly with the panels of the main switchboard. The three pumps supply the water required for the complete hydraulic system, to which all the elevators of the store are connected. The arrangement of piping for this system is of a novel character, and has proved highly satisfactory. There is one pressure main from the discharge openings of the pumps which runs through the whole building, past each of the elevator machines. This pressure main is connected to two compression tanks, one in each end of the building. These two tanks are set at the same level and carry their water lines at the same height. The connection for each elevator machine is taken from the main at a convenient point. There is a return main, paralleling the pressure main, into which each elevator machine discharges, and this return main is connected to each of two open, or "surge," tanks located near the compression tanks. These tanks are connected to the suctions of the pumps. With a suitable arrangement for removing entrained air from the suction line, the operation of the system is perfect. During the hours of light load, one of the 300-gallon units operating at normal capacity will carry the service. During the hours of heavier service the 500-gallon pump will take care of the load, and during the hours of maximum load either of the 300-gallon machines, together with the 500-gallon one, will carry the load.

**Library Illumination.**—An excellent article on the illumination of libraries appears in the *Western Electrician* of Chicago. The author points out that the use of gas is a serious mistake in any library where electricity is available, and that the relative prices of the two should have little weight in determining which illuminant to use. Favourable conditions of atmosphere are a fundamental requisite where intense mental work is to be performed, and in no gas-lighted room can the purity of the air be compared with the atmosphere of an electrically illuminated chamber, with any possibility of better conditions in the former case, granted the same ventilation facilities in each. It is well known, also, that the depreciation of books and pamphlets is much greater in the vitiated air of a gas-lighted apartment than in the room lighted by electricity, so that in the long run it is poor economy to use gas, even if its price in some cases is considerably lower than the charges for current. This is because many of the acquisitions of a progressive library cannot be replaced when they become worn out, and every effort to prolong the useful life of a book is therefore to be commended. A point is made by the author of the great importance of uniform illumination. The brilliance of new Welsbach mantles is attractive in this respect, but their rapid depreciation discounts them. Two kinds of illumination are ordinarily required in libraries—general and special. The former provides for the convenient movement of persons and books from place to place and the easy consultation of volumes upon shelves, determination of titles, numbers, etc. The latter is of a concentrated nature, enabling exacting eyework to be done in certain specific places, such as reading and study tables. For all library work it is probable that the incandescent lamp will in time be recognised as capable of being best fitted to meet the most varied conditions. In large public libraries the use of magnificent marble decorations constitutes a common feature of the architecture, and the requisite designs of ornamental electric lamps now available for such work far surpass in beauty anything that gas illumination has to offer. In fact, the equipment of such a building as the Congressional Library at Washington or the public library in Boston with gas lamps is practically inconceivable. Even the stacks demand the clean and flexible electric bulb, due care being taken to provide swinging lamps with guards as a prevention against fire. It would be difficult to name an installation, says the author, where the application of electric lighting to library work equals that of the Congressional Library. In decorative effects and brilliance of illumination the lay-out deserves the admiration of every electrical engineer and central-station man who visits Washington. The article concludes with the following admonition to central-station managers: "Wherever a gas-lighted library exists in the same town with a central station, it should be the constant effort of the manager to add the library lighting to his load."

**The Light Railways Act.**—The particulars we published last week of the report issued by the Light

Digitized by Google

Railway Commissioners seem to indicate an unmistakable decline in the popularity of the Light Railways Act. The state of affairs in regard to procedure under this statute is concisely illustrated by the following table relating to the orders confirmed during the past four years:

| Year. | Number of orders confirmed. | Mileage. | Estimated cost. |
|---|---|---|---|
| 1901 ..... | 49 ..... | 337 ..... | £2,629,725 |
| 1902 ..... | 33 ..... | 149 ..... | 1,192 000 |
| 1903 ..... | 37 ..... | 179 ..... | 2 019,800 |
| 1904 ..... | 21 ..... | 97 ..... | 801,300 |

The orders confirmed by the Board of Trade since the commencement of the Act in 1896 down to Dec. 31 last number 237, representing an estimated expenditure of over 11 millions. These are tolerably substantial figures, though it has to be remembered, of course, that some of the schemes failed to arrive at fruition, and where the construction of light railways has set in on a large scale it cannot be expected that the returns will continue to show an increase year by year, especially with the comparatively limited area of this country; but it needs a much more extensive adoption of the Act than has been the case if its ostensible object is to be achieved. In France and Belgium, where light railways are largely State-aided or rate-aided, excellent results have been attained of recent years, and the inference appears to be that if our agricultural districts are to be adequately served in this respect, a larger degree of assistance from the public funds must be forthcoming. Such a step would probably be met with the usual chorus of disapprobation by the anti-municipal alarmists, but we think that this is a case where State or municipal aid might justifiably be rendered. The anti-municipal section have a good show of reason on their side in some of their protests, but private enterprise is not likely to do much unaided in the way of constructing lines in rural districts for goods traffic, while with a fair degree of municipal support they may find some inducement to do so. The Act of 1896 confers power on the Treasury and on local authorities to render facilities for such schemes, but to effect the object in view a much larger amount of support than has hitherto been available is necessary. A comprehensive scheme of light railways in rural districts should contribute materially in assisting our decadent agricultural industries. We gave in our issue of the 9th inst. some particulars of a scheme presented to the Chicago branch of the American Institute of Engineers by Mr. J. R Cravath for a modified type of light railway for passenger and goods traffic in rural districts. Mr. Cravath estimated that by using a 28in. gauge and lighter rails a light railway could be constructed for £1,570 per track mile, exclusive of expenditure for right-of-way. He estimated, from various data, that a revenue of £330 per mile would be possible, on which there would be a surplus of £80. Possibly his figures are a little optimistic, but some relaxation in the requirements of the Act, coupled with a larger measure of State or municipal support, would probably result in lines being constructed in suitable areas now unserved.

**Electroculture.**—Our contemporary the *Scientific American* has an interesting article on what it designates electroculture. The author remarks that the flora of the north polar region is remarkable for rapid growth, fertility, and brilliancy of colouring, phenomena which seem incompatible with the climate. The Arctic summer, though nightless, is very short, the sun is low, and its rays are often intercepted by fog and clouds, so that it cannot furnish an amount of light and heat favourable to very rapid growth. The investigations of Prof. Lemstrom, of Helsingfors, and others, tend to show that electricity exerts a great influence on the growth of plants, and this view is confirmed by the luxuriant vegetation of the zone of action of that violent electrical manifestation, the aurora borealis. Furthermore, a close connection has been found, in Finland, between fruitfulness and frequency of auroras. Finally, Lemstrom was led to attribute to the sharp points of plants, such as the beard of grains, the function of "lightning rods," which collect atmospheric electricity and facilitate the exchange of the charges of the air and the ground. His early experiments showed that electrified plants had more vigorous growth than others, the increase in weight approximating to 40 per cent. These experiments were made with barley, grain, and straw. In the following year the experiments were extended to various plants. The results were contradictory in some respects, and showed that the advantage derivable from electroculture depends also upon other factors, such as temperature, moisture of air and soil, and the natural fertility and the manuring of the latter. The supply of water proved to be of especial importance. Extensive experiments with potatoes, carrots, and celery showed increases in crop of from 30 to 70 per cent. Small differences, possibly due to extraneous causes, appeared when the direction of the current was reversed. Other field experiments gave increases of 45, 55, occasionally 85 per cent. for grain and 95 per cent. for raspberries, while cabbage, tobacco, flax, turnips, and peas grew better without electrification than with it. Lemstrom then, in order to test the effect of climate on electroculture, transferred his experiments from Finland to Burgundy, where he found his earlier observations confirmed, particularly in regard to the great influence of irrigation. Other investigators attacked the problem from a different side, endeavouring to affect by electrification, not the growing plant, but the seed. The Russian botanist, Spechniew, submitted grain to electrical action, and thought that it sprouted earlier and more vigorously than grain not so treated. Pautens, who repeated Spechniew's experiments on a larger scale, came to the conclusion that electricity had no effect on dry seeds, but that it promised excellent results when applied in connection with moisture—which in itself promotes germination. The same conclusion was reached by Kermey, who electrified grain strewn on moist sand in a glass cylinder through which it could be observed. The author considers that the cultivation of fruits and vegeables, particularly under glass, may become a commercial possibility, for electroculture promises not only greater but also earlier crops. Floriculture offers another promising field for the application of electrical methods. The author proceeds: "All this, however, belongs to the future. Much study and experiment and probably many failures must precede the general introduction of electroculture, though the results already obtained are certainly promising." In conclusion, the author gives an explanation of the effect of electricity upon plants. These transform the energy of the sun's rays into chemical energy. Though the heat produced by the electric current may have some direct effect, especially in germination, the electrical energy supplied cannot, in general, replace or even greatly reinforce the energy of sunshine. It is rather to be regarded as a stimulus to metabolism and all the vital processes. One of these is the capillary elevation of water, which is promoted by a positive electric current flowing upward. This is one possible explanation of the promotion of growth by electricity, and though in some cases the best effect is obtained by directing the positive current downward, or in the opposite direction to the assumed principal flow of sap, these exceptions may mean that more food is supplied by the leaves than is commonly supposed. Another possibility is an increase in activity in both leaves and roots.

## THE CLYDE VALLEY ELECTRICAL POWER COMPANY, LIMITED.

For many years the Clyde and the neighbouring district has been famed as a centre of industrial and engineering importance, and it is the avowed object of the Clyde Valley Electrical Power Company, which was initiated by local enterprise, to help manufacturers in the district surrounding Glasgow to maintain the position they have so long held, and to aid them in competing as keenly as ever in the world's markets. The company was incorporated in 1901, and has obtained powers over an area extending along the Clyde Valley from Craigdoran and Port-Glasgow in the west to Lanark and Shotts on the east. This area, which comprises about 750 square miles, contains the most important manufacturing and coal-producing district in Scotland.

The company have taken over the provisional order which was granted to the burgh of Clydebank in 1901. This was sanctioned by Parliament in 1904, and enables the company now to supply electricity for both power and lighting in the burgh, for which purpose special plant has been installed. The city of Glasgow, and the burghs of Govan, Partick, Port-Glasgow, Paisley, and Hamilton, although actually situated in the above area, are not included in the company's schedule unless any of them should elect to take a supply. Under their Act of Parliament the company were empowered to acquire land for the erection of generating stations at Yoker and Motherwell, five miles and 15 miles out of Glasgow respectively, and in September, 1902, a contract was entered into with the British Westinghouse Electric and Manufacturing Company, Limited, for the erection and equipment of these two stations and the various sub-stations that are dotted over the area. Fig. 1 is a diagram showing the cable routes, present and future, and the positions of the generating and sub-stations.

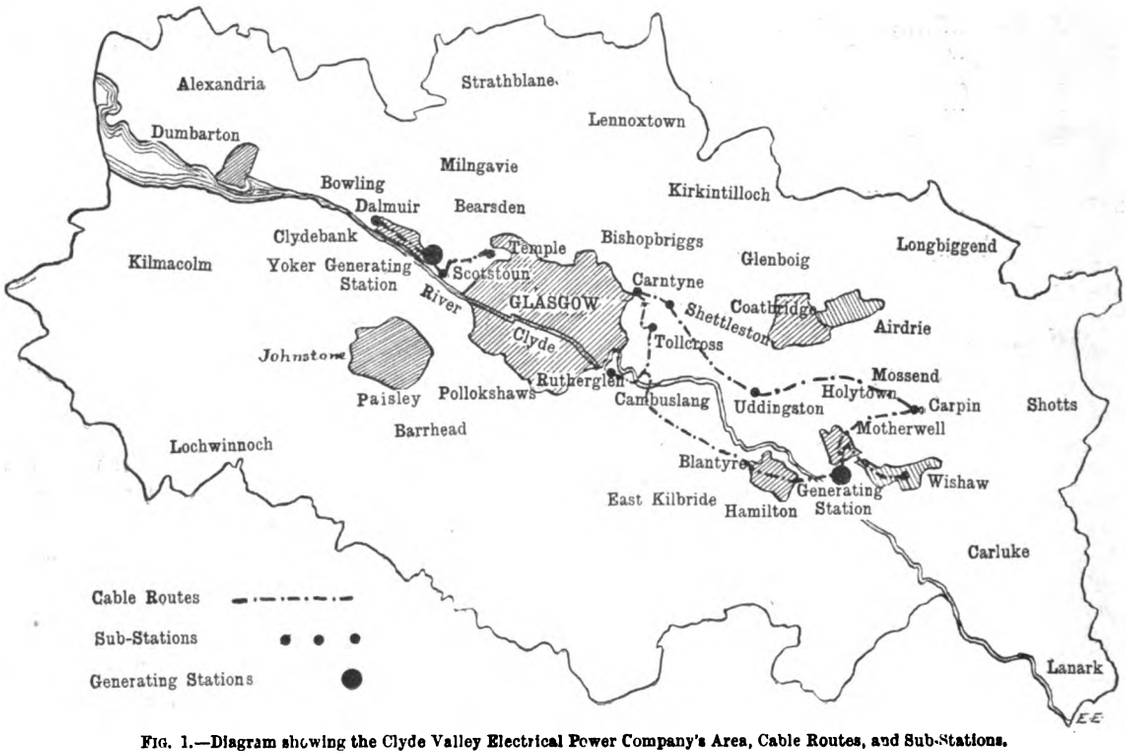

FIG. 1.—Diagram showing the Clyde Valley Electrical Power Company's Area, Cable Routes, and Sub-Stations.

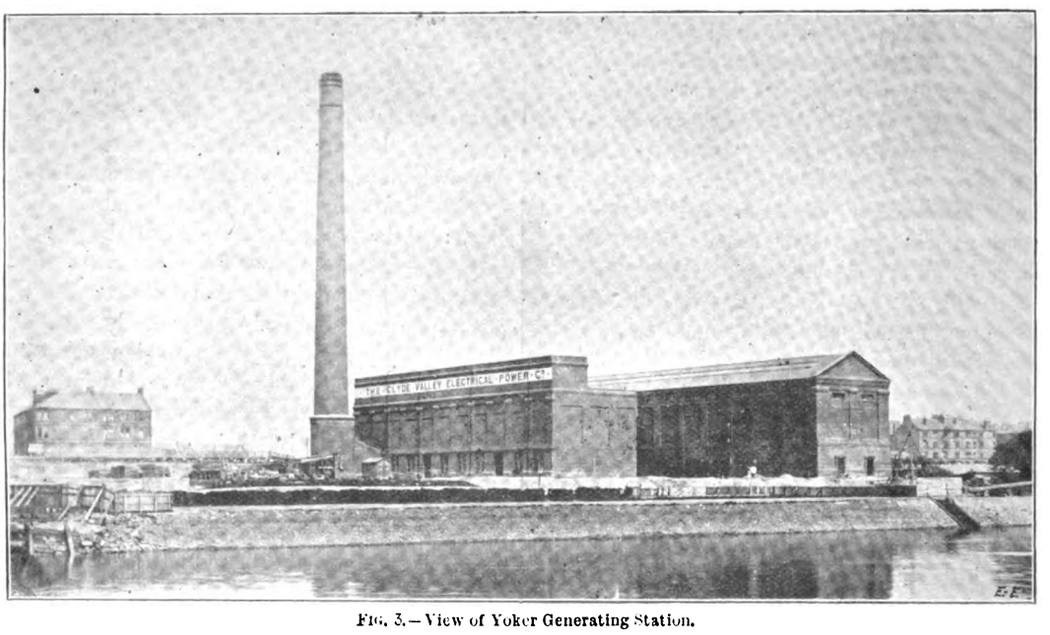

FIG. 3.—View of Yoker Generating Station.

### YOKER POWER STATION.

Figs. 2 and 3 are respectively a plan and view of the Yoker generating station, which is situated on the banks of the Clyde, where an unfailing supply of water for condensing purposes is available. The Motherwell station, being situated at a higher elevation and above the level of the River Clyde, depends for its water supply for condensing purposes on electric pumps working against

a head of 140ft. As shown in Fig. 2, the offices occupy part of the south end of the engine-room, being placed adjacent to the switchboard galleries. Accommodation is provided here for the station superintendent, storekeepers, and timekeepers. The offices are divided off from the switch galleries by iron doors, and everything is of a thoroughly fireproof construction, special attention having been paid to this important matter.

*Boiler-House.*—The boiler-house has an internal measurement of 186ft. long by 50ft. wide. It is well lighted, and is designed in every way to afford the maximum of convenience. There are at present four double-drum Babcock and Wilcox water-tube boilers in position, each having a heating surface of 4,400 square feet and fitted with superheaters capable of imparting 150deg. F. of superheat. The steam pressure is 175lb. per square inch. The boilers are connected to a main flue passing along the back, and a Green's economiser of two sections and 432 10ft. tubes is installed between this flue and the chimney, the usual by-pass flue being provided. The chimney is built of special perforated and moulded bricks on the Alphons Custodis system, and is 225ft. high above the foundations, with an internal diameter at the top and bottom of 11ft. and 14ft. respectively. It is lined with firebricks up to a height of 85ft. above the top of the foundations, which extend to a depth in the ground of 22ft. The base of the foundation occupies a space of 2,116 square feet, and the weight divided over the entire area is two tons per square foot, allowance being made for wind pressure. Each of the boilers is fitted with a Roney mechanical stoker, manufactured by the British Westinghouse Company, and adapted for burning efficiently a cheap class of coal. These are driven through a special worm gearing by two 4½in. by 4in. 5-h.p. Westinghouse standard engines, running at 400 revolutions per minute, and situated in the boiler-house. The coaling arrangements of the power station are most complete, and from start to finish the fuel is untouched by hand. Coal is brought in wagons to the company's private siding, where it is dumped by a hydraulic ram into the crusher-pit, passing through a crusher and screen

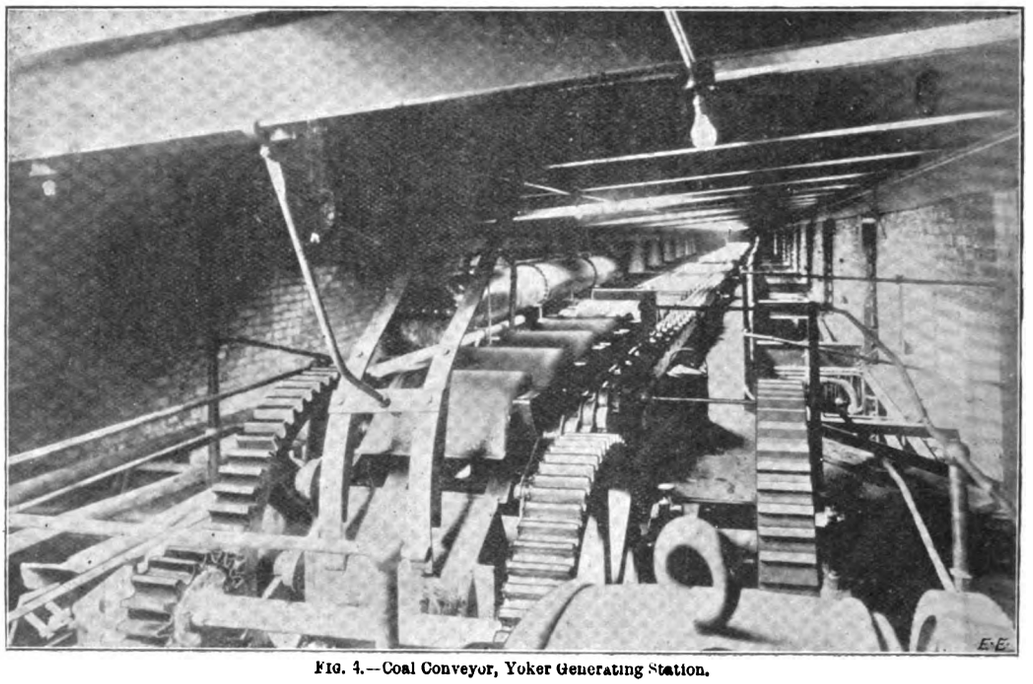

FIG. 4.—Coal Conveyor, Yoker Generating Station.

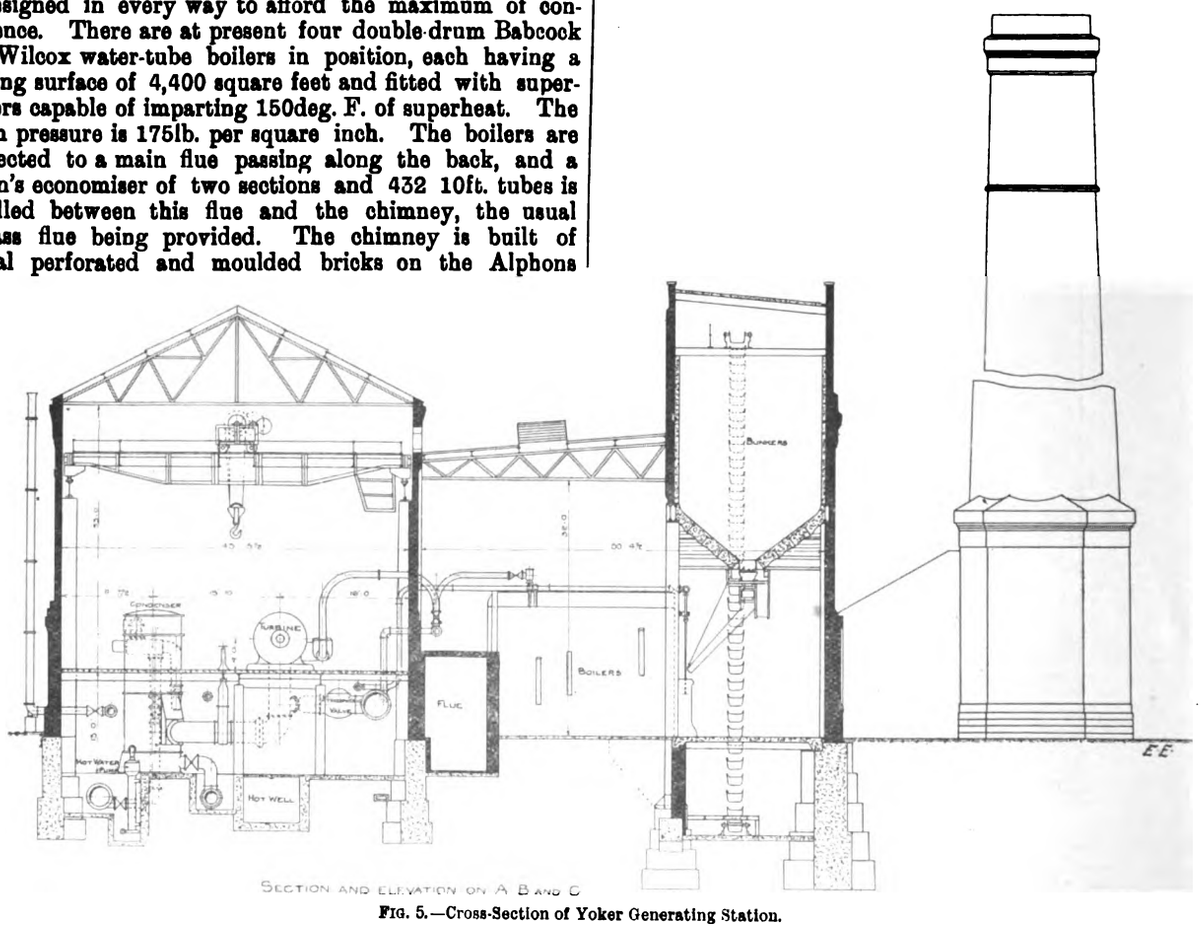

FIG. 5.—Cross-Section of Yoker Generating Station.

operated by a 10-h.p. enclosed shunt-wound motor running at 650 revolutions per minute. It is there picked up by a bucket conveyor (Fig. 4) constructed by Messrs. Graham, Morton, and Co., and carried to the storage bunkers over the boiler-house. This conveyor, which is driven by a 15-h.p. enclosed shunt-wound motor, is also used for carrying the ashes away from the boiler-house. From the bunkers the coal passes automatically to the stokers, being weighed—also automatically—in transit, and the number of hundredweights used recorded on an indicator. To prevent the coal sticking in the shoots a motor-operated agitator is installed, which keeps it constantly on the move.

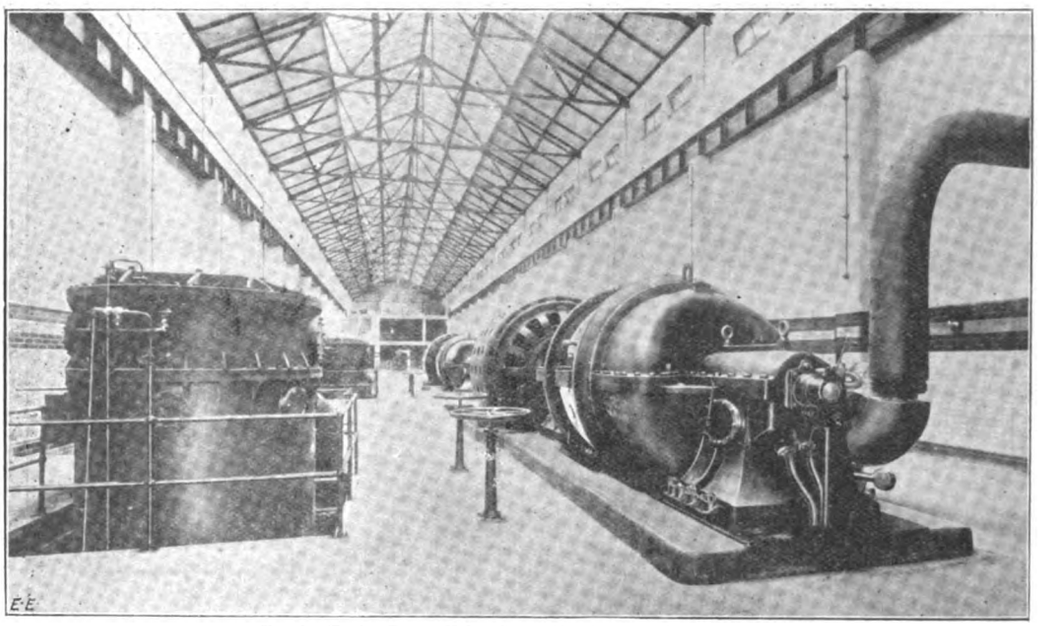

FIG. 6.—Engine Room, Yoker Generating Station—General View.

*Engine-Room.*—The engine-room consists of two floors, one on the ground level (Fig. 5) and one in the basement, the latter containing most of the auxiliary machinery. The turbine condensers, which are of the Mirlees-Watson vertical surface type, each with 6,250 square feet of cooling surface, are placed here, their upper ends projecting through the main floor a few feet. Each turbine exhausts directly into its own condenser, and each condenser is provided with a steam-driven, two-stage, dry-air pump situated in the basement. Arrangements have also been made for exhausting to atmosphere if necessary. The circulating water for the condensers is drawn from the Clyde, running by gravity into a large circular well 18ft. in diameter and of a depth below water-level of 9ft. There are two 30in. pipes leading into the well from the river, and the water is drawn out through a 36in. cast-iron pipe by means of a steam-driven centrifugal pump placed in the basement. After passing through the condensers the water is discharged by a 36in. pipe into a tank on the bank of the river. The condensed water is pumped into the hot-well, which is also in the basement, by a centrifugal pump driven by a 6-h.p. vertical-shaft shunt-wound motor running at 625 revolutions per minute. From here it passes to the suction of the two feed-pumps, which are of Messrs. J. and P. Hall and Son's tandem, compound, double-acting type, each capable of delivering 9,600 gallons per hour against a boiler pressure of 175lb. The make-up water is taken from the city mains, that of the Clyde being unsuitable for boiler-feed purposes; there is, however, a stand-by suction from the river for use in case of emergency. The exciter sets have their separate surface condenser, which is of the Worthington Pump Company's make, and has 600 square feet of cooling surface. In addition to the above auxiliary plant, there is installed a feed-water heater by Messrs. Joseph Wright and Co., having a heating surface of 700 square feet.

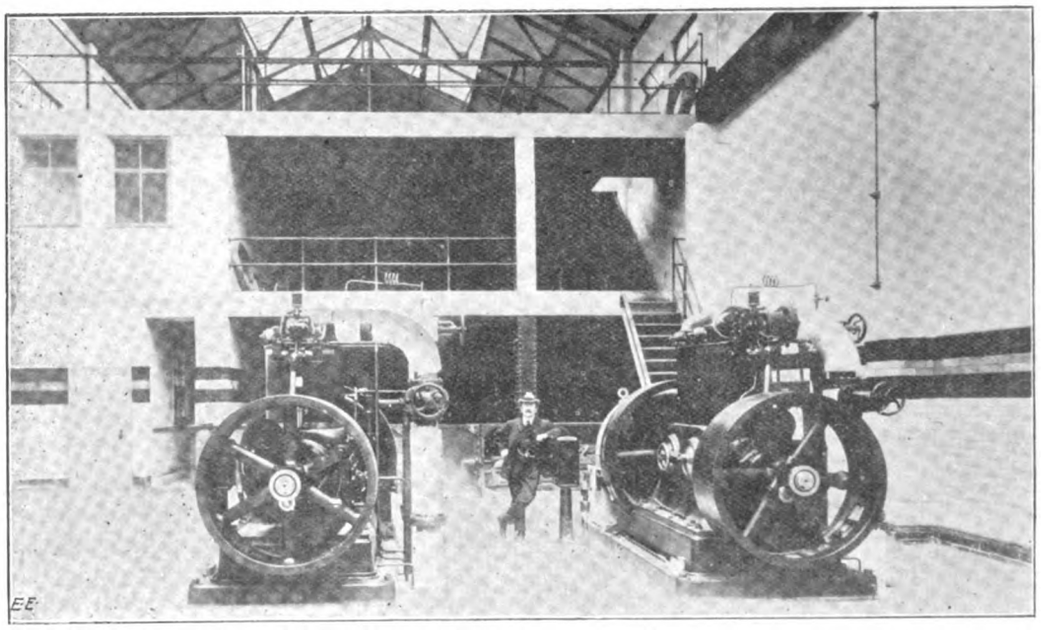

FIG. 7.—Exciter Sets, Yoker Generating Station.

*Generating Plant.*—The upper and principal floor of the engine-room measures 252ft. long by 43ft. 5½in. wide. It is well lighted from the roof, the walls are faced with white

Digitized by Google

glazed bricks, and the floor throughout is paved with Italian mosaic work. At the north end are situated the switchboard galleries and offices, which have an inside measurement of 53ft. by 43ft. 1in. wide. The main generating plant at present installed consists of two Westinghouse-Parsons steam-turbine units (Fig. 6), each with a normal capacity of 2,000 kw. and an overload capacity of 3,000 kw. The speed is 1,500 revolutions per minute, which corresponds to a peripheral velocity of the rotating part of five miles per minute. The turbines are of the latest double-flow pattern, steam entering at the centre and exhausting at both ends, and each contains no less than 20,000 blades. These are securely fixed to the steel drum, and are of drop forged steel in the first series, and special metal at the low-pressure end so as to prevent corrosion due to the wetness of the steam. The cylinder is of close-grained cast iron, and the rotor consists of a rolled-steel drum fixed to the shaft by the aid of forged-steel umbrella-shaped discs shrunk into the drum and pressed on the shaft. Each of the turbines is directly connected to a Westinghouse 2,000-kw., 11,000-volt, three-phase, 25-cycle generator of the rotating-field type. These are of the normal Westinghouse design. The two-pole field magnets consist of a solid forging of Whitworth fluid-pressed steel combining high magnetic properties with strength, and the armature of laminated iron wound with copper bars in practically closed slots is supported by a heavy cast-iron frame divided horizontally. The starting, stopping, and speed variations of the generators is under control from the switchboards by electrical means, current for this purpose being taken from the exciters. The oiling of the turbines is carried out on the gravity system. A large tank in the basement of the engine-room receives the oil overflowing from the bearings, which is then passed through coolers and raised by a special oil-pump to a tank in the roof of the boiler-house, flowing from thence by gravity under a head of 50ft. back to the bearings. Oil-pressure gauges are provided on the latter in order to indicate at a glance how the apparatus is working. The engine-room as at present constructed will accommodate one more 2,000-kw. set and a fourth unit of 3,500 kw which will eventually make the total capacity of the station 9,500 kw. The additional sets will be added as soon as one of the present units is loaded up, so that there will be always one spare set ready at any moment in case of accident.

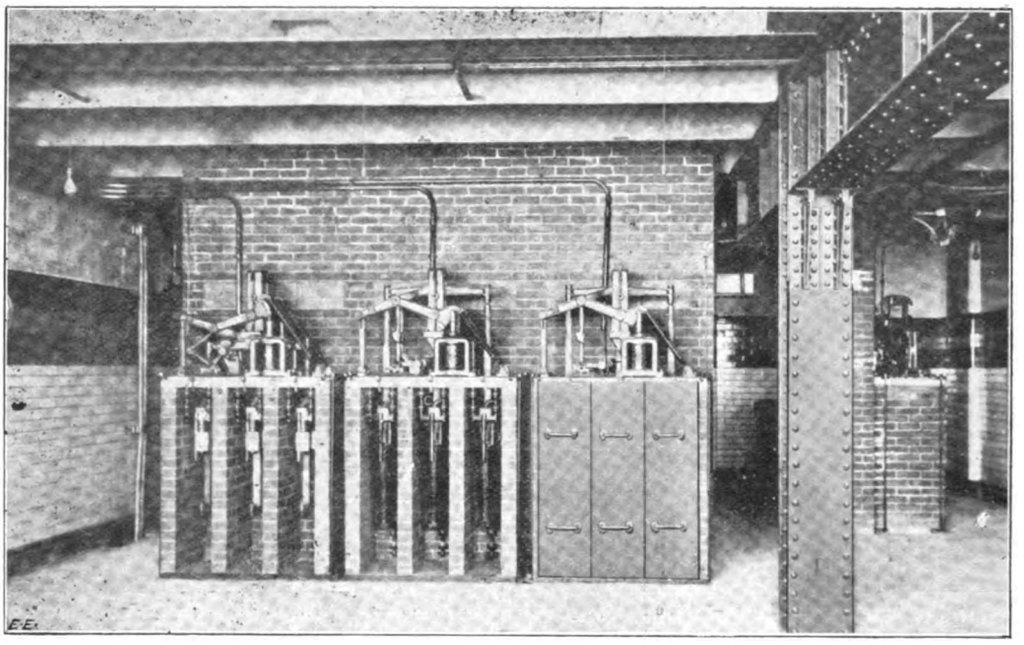

FIG. 8.—Switchgear, Yoker Generating Station.

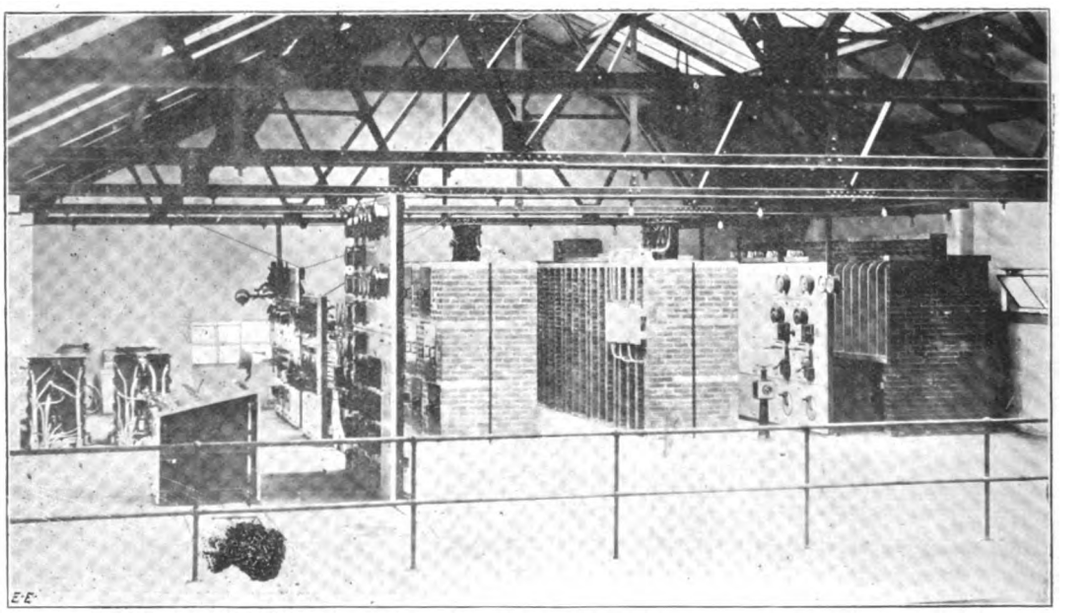

FIG. 9.—Top Switch Gallery, Yoker Generating Station—General View showing 'Bus Bar Chambers and Motor-Generator Switchboard on right and Control and Instrument Boards on left.

*Exciters.*—The two exciter sets (Fig. 7), situated at the south end of the engine-room, are each capable of furnishing the exciting current for both the main generating units at present installed. They are of 75 kw. capacity each, and

Digitized by Google

consist of a Westinghouse 11in. by 19in. by 11in. vertical compound engine, running at 290 revolutions per minute, coupled direct to a 125-volt compound-wound dynamo. In addition to their natural function, these exciters supply current for operating the motors of the coal and ash conveyor, crushers, agitators, economisers, pumps, travelling crane, etc., and also for the electrically-operated main and other switches.

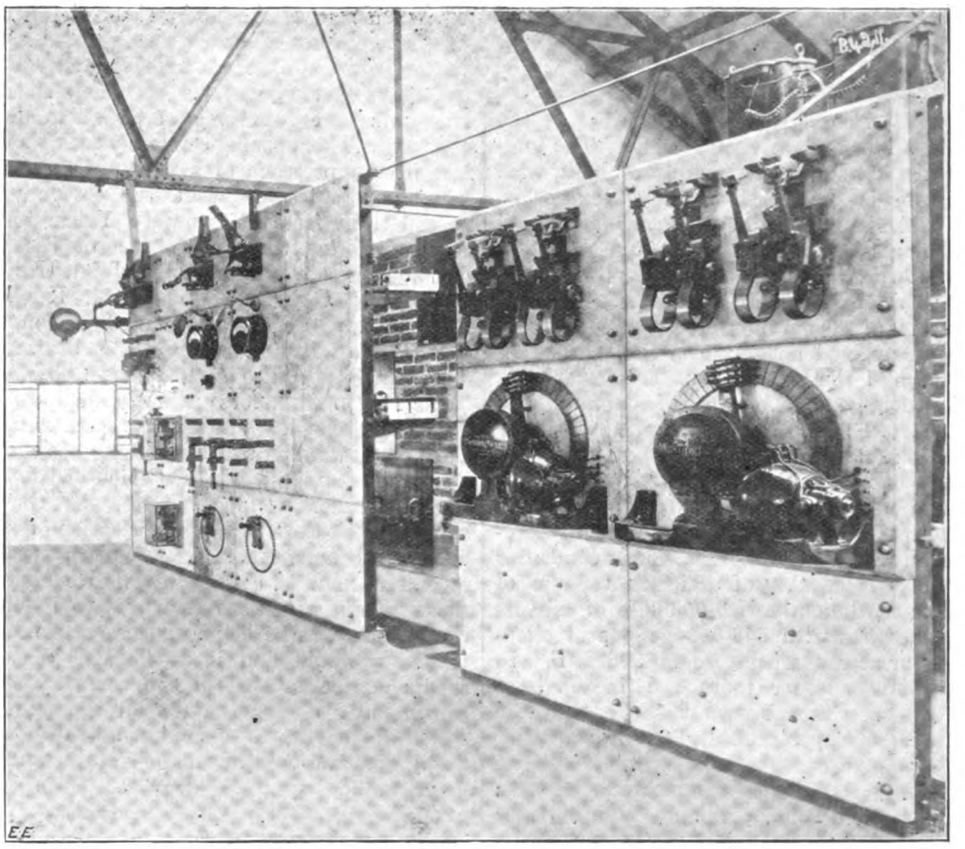

FIG. 10.—Automatic Rheostats, Yoker Generating Station.

*Travelling Crane.*—The travelling crane is by Messrs. C. and A. Musker and Co., and has a span of 42ft. It is of 30 tons capacity, having three motors of the Westinghouse type S.B., totally enclosed pattern, series wound. These motors are of the following horse-powers and speeds: lifting, 25 h.p., 460 revolutions per minute; longitudinal travel, 10 h.p., 650 revolutions per minute; transverse travel, 4 h.p., 935 revolutions per minute.

*Switchgear.*—The whole of the switchgear is contained in the three galleries (see Fig. 7) at the south end of the engine-room. That on the ground floor and the first gallery are devoted to the oil switches (Fig. 8) and feeders.

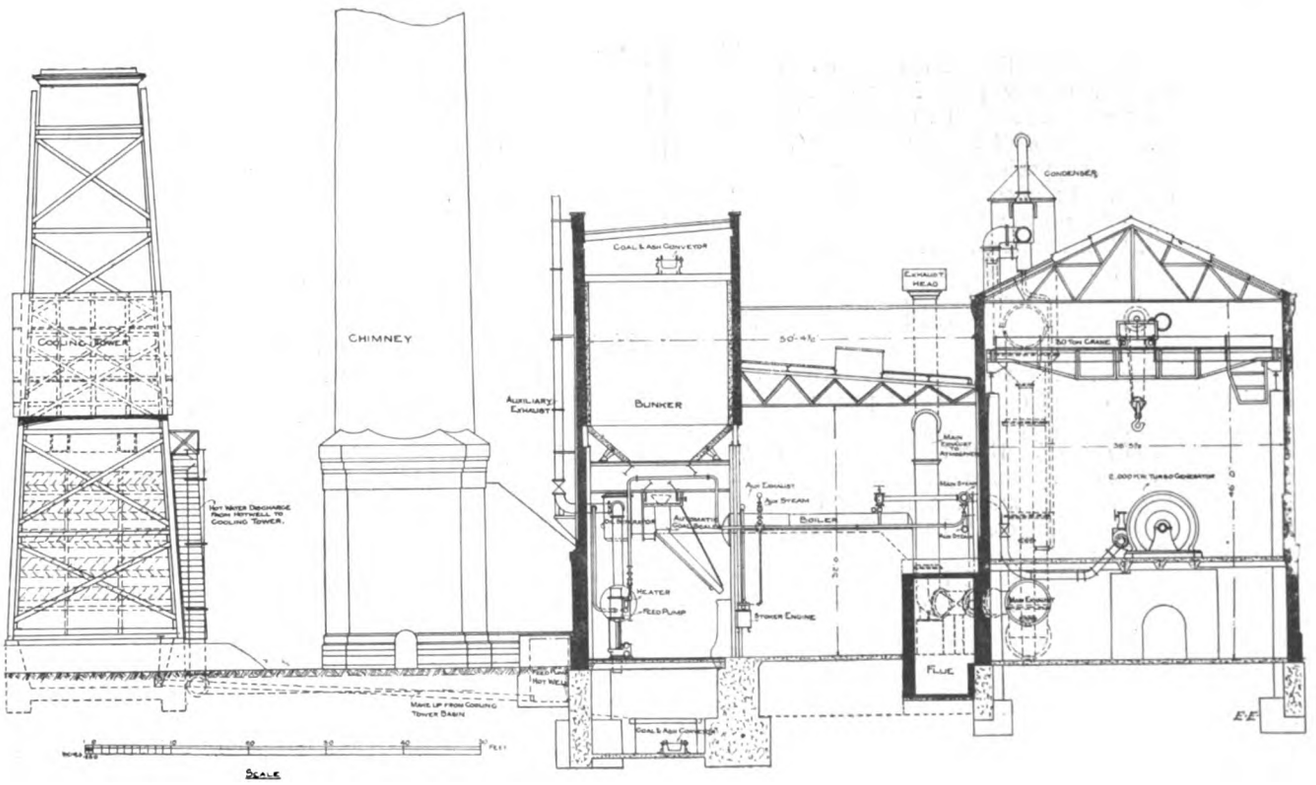

FIG. 11.—Cross-Section of Motherwell Generating Station.

On the third or top gallery of the switchboard (Fig. 9) are placed the main 'bus bars in brick compartments, and the main controlling board, as well as the resistances, etc. Following the latest practice, the control board consists of

Digitized by Google

a small desk directly facing the various instruments, such as ammeters, voltmeters, power factor indicators, relays, etc. All the main switches and smaller gear are electrically operated from this desk by the exciter current, as before mentioned, and the speed of the turbo-generators and their starting and stopping is also controlled from here. Automatic rheostats (Fig. 10) are provided.

MOTHERWELL GENERATING STATION.

The Yoker and Motherwell power stations are of the same size and almost identical in arrangement. The foregoing description therefore applies generally to both, with the following exceptions. The Motherwell station (a cross-section of which is shown in Fig. 11) is not so favourably placed as Yoker, being 400 yards from and 140ft. above the level of the river. A cooling tower of Messrs. Balcke and Co.'s make has, therefore, been installed for cooling the circulating water. It is of the natural-draught enclosed type, 73ft. high, and is constructed entirely of wood thoroughly soaked in carbolineum of the best quality. The tower has a normal capacity for cooling 200,000 gallons of water per hour from 120deg. to 80deg. F., when the temperature of the air is 70deg. F. or less; and the amount evaporated under ordinary conditions of atmospheric temperature does not exceed 2½ per cent. of the water circulated. The condensing plant is another of the features in which the Motherwell station differs from Yoker, a barometric jet condenser being installed. This is capable of giving a vacuum of 27·5in. when dealing continuously with 80,000lb. of exhaust steam per hour, if supplied with 348,000 gallons of circulating water per hour at a temperature of 80deg. F. In connection with this condenser there are installed at Motherwell two Alberger-Corliss two-stage dry vacuum pumps, one of which is capable of dealing satisfactorily with the air in the condenser when one turbine only is in operation. The dimensions of these pumps are as follows: diameter of steam-cylinder 10in., diameter of air-cylinder 24in., stroke 24in. Their normal speed is 100 revolutions per minute, but they are capable of working at a lower rate if necessary. The steam and exhaust valves are of the Corliss type, and so designed as to permit of a high speed in cases of emergency without noise or jar.

DISTRIBUTION.

Six feeders are provided for distribution from Yoker, and all are protected where they enter the building in the basement by Westinghouse lightning arresters. The cables for supplying power to any part of the district between Clydebank and Scotstoun as well as to Temple are practically finished. They are all laid in duplicate, so that in case of any accident happening to one of them, the spare one can be connected immediately while the duplicate is being repaired. As previously stated, the Clyde Valley Electrical Power Company are authorised to supply in the adjacent burgh of Clydebank. For this purpose special plant has been installed, consisting of two 150-kw. motor-generator sets. Each set is provided with a small motor coupled direct to the shaft, which serves for starting and running up to speed. These motor-generators are situated in the first switch gallery of the Yoker power station, and the switchboard controlling the distribution to this area is placed on the top gallery. Both the high and low tension cables for the Clydebank district were supplied and laid by Messrs. Henley and Co., and the British Insulated and Helsby Cables have been entrusted with the extra high-tension cable work throughout the entire area. The number of sub-stations at present provided is 10 for the Motherwell district and two for Yoker. These two districts will not at present be connected in any way, although they may be in the future. All the transformers were supplied and erected by the British Westinghouse Electric and Manufacturing Company, Limited.

The general arrangement of the entire plant was designed by Messrs. Strain and Robertson, consulting engineers, of Glasgow. Mr. H. A. Barnett, resident engineer to the Clyde Valley Company, has had the supervision of the erection and installation of both power stations and the distributing system since the commencement.

The company's charges for lighting are a flat rate of 3½d. per unit or on the maximum demand system of 6d. and 1d. For power their prices vary from 3d. to ·68d. according to the quantity taken.

## Opening of Yoker Power Station.

By the opening of their first power station at the little town of Yoker, on the banks of the Clyde, the Clyde Valley Electrical Power Company inaugurated not only the real setting to work of their own large undertaking, but a most important development in the electrical industry in Scotland—viz., the supplying of power in bulk by a private company. This opening ceremony took place on Wednesday last in the presence of a party of some 300 gentlemen, who, on the invitation of the company, journeyed by special train from Glasgow to Yoker for that purpose. Among others, there were present Sir David King, a director of the company; Sir John Ure Primrose, Lord Provost of Glasgow; Charles M. King, Esq., Andrew Rintoul, Esq., Prof. Barr, Prof. Jamieson, W. W. Lackie, Esq, Provost Taylor, of Clydebank, Prof. Magnus Maclean, J. M. M. Munro, Esq, and Robert Robertson, Esq.

Sir DAVID RICHMOND, who presided, said that it was 2½ years since they had commenced operations, and it was only their determination to have nothing but the best machinery and the most up-to-date plant which had delayed the completion of the work so long, but now that they were ready to start to work they had the satisfaction of knowing that for economical and satisfactory working they had a plant second to none in this country. He hoped that many of those present would see their way to become customers of the company, as he believed there was no doubt whatever that they would find it economical to take energy from such a station as that of the company, which would run continuously day and night all the year round, and in which the chance of breakdown was so remote, owing to the duplication both of the generators and the conductors. They would be able to see that their site permitted of extensions on all sides. Their machinery would be ready for continuous running in the course of a month or so, and in two months' time their second power station, situated at Motherwell, would also be ready to give a supply.

The LORD PROVOST OF GLASGOW (Sir John Ure Primrose) was then called upon by Sir David to say a few words. He said he had great pleasure in being present at this very important departure in commercial adventure. It was commerce linking itself with science, and placing the joint product within the purchasing power of the community. He thought that in this undertaking they had one of their greatest hopes for a purer atmosphere. He heartily wished the company every success.

Sir David Richmond then formally started one of the turbo-generators, and called upon Sir John Ure Primrose to start the other one.

## THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

### Thirteenth Annual Meeting—Dortmund and Essen.

[FROM OUR SPECIAL CORRESPONDENT.]

(*Continued from page 848.*)

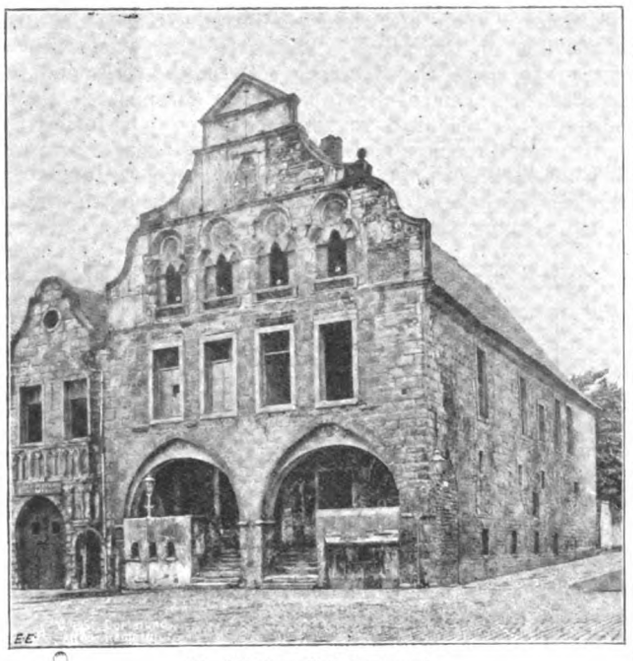
Business proceedings were commenced on Monday morning in the old town hall, Dortmund, a building of some historical interest, whose quaint appearance before restoration is shown in the accompanying illustration (Fig. 1). Contrary to what one might surmise from an exterior view, the accommodation afforded was good and ample. Prof. Budde presided over the meeting. The honorary guests included the mayor, a Post Office official, and representatives of local industries. A few words of greeting having been addressed to them from the chair, these deputies then proceeded in turn to welcome the meeting to the town. It has often appeared to me that this sort of thing is a trifle overdone on these occasions. When representatives of various local institutions, followed, as has sometime happened, by a Government official or two and deputies from neighbouring universities, feel called upon to make tedious speeches, it entails a sacrifice of valuable time which would otherwise be available for serious discussion. True, it is indicative of the value at which the work of the

Digitized by Google

association is estimated in wide circles, and may thus serve to stimulate effort, but the practical recognition obtained is far better.

In the course of his address which followed, Prof. Budde briefly reviewed recent progress of the German electrical industry. He said he regarded the improvement of the single-phase motor as one of the most important developments of modern times, since it promised to be the means of superseding steam traction on railways. Electric traction had already been introduced on the Hamburg-Altona-Blankenese line of the Prussian State Railways. Other and longer sections would follow when it had been conclusively demonstrated that energy could be conveyed to the trains through a simple system of twin overhead conductors. A magnificent opportunity had been lost in regard to the Simplon Tunnel, traffic through which, report had it, would be worked by steam locomotives from the autumn of the current year. It seemed to him extraordinary that in a country so cut out for electric traction the newest and greatest tunnel should be relegated to such a fate.

After the great and justifiable sensation caused by the success of the express train trials in 1903, the fact remained that no tangible commercial progress had been made in this direction, and unless the spirit of enterprise increased at home it was not unlikely that the first express railway of German invention would be constructed, say, between



The Old Town Hall, Dortmund.

Philadelphia and Baltimore or between New York and Milwaukee, and that Germans would thus be robbed of the fruits of the pioneering work by their enterprising cousins across the Atlantic.

With regard to submarine telegraphy, the laying of the second German Transatlantic cable by way of the Azores was worthy of note, as was also the laying of a cable by the German Netherlands Telegraph Company, which completed the connection between Berlin and the Caroline Islands, and the new cable between Constance and Constantinople, which put Germany into direct communication with the near East.

The increasing employment of metal returns for land telegraphs and the laying of the wires underground in large towns also represented noteworthy progress. Wireless telegraphy had been subjected to a severe test at the seat of war, and had proved its worth. It was now rapidly winning way into all armies and marines. Nor had its commercial possibilities been neglected, but development in the latter direction would apparently have to be subservient to patriotic considerations in case of war.

Electric transmission of power, especially in mines and ironworks, continued to make steady progress. During 1904 legislators in Prussia, Bavaria, and Saxony had busied themselves with measures relating to the inspection of electrical installations. In Prussia a Bill had been passed to enable official inspection of such installations at the expense of the owners.

It appeared from the annual report, which was next presented to the meeting, that the membership of the V.D.E. is now 3,636, an increase of 250 on the year, while the funds in hand amount roughly to £6,400.

Last year's report*, it will be remembered, made reference to steps taken by the Verband in connection with the introduction of the above-mentioned Government Bill dealing with the cost of inspecting and testing electrical installations It was their object to secure that the Bill would not be detrimental to the further development of the industry. Other associations co-operated in this endeavour, with the result that the measure as passed by the Abgeordnetenhaus duly safeguarded the interests involved. Unfortunately, however, the Herrenhaus, before which the Bill came for final sanction, did not take the same view of the matter, and cut out the clause which had been added in response to the wishes of the Verband. It is to be inferred, then, that the Bill as it now stands provides no guarantee than the inspection shall be by practical electrical engineers, nor that the regulations adopted by the Verband shall be taken as a basis for judgment on the condition of an installation inspected.

*(To be continued.)*

## CORRECT POSITION OF LIGHTNING ARRESTERS IN THE CIRCUIT AND THE EFFECT OF CHOKING COILS.

In a recent number of the *Elektrotechnische Zeitschrift* F. Neeson describes some interesting tests carried out at the Reichsanstalt for the purpose of determining whether

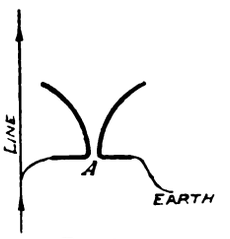


Fig. 1.

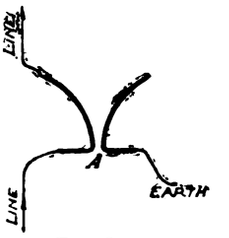

Fig. 2.

a lightning arrester is most effective when connected as a shunt to the circuit to be protected, as in Fig. 1, or when in series with the circuit as in Gola's system (Fig. 2). (See *Electrical Engineer*, March 3, 1905. p. 339.) The results of the tests point uniformly to the latter as being the most effective, although the former is the arrangement most commonly adopted at present.

The tests were only on a laboratory scale, but they bring out the point in question quite clearly. The connections employed are shown in Fig. 3, where J represents an influence machine, L a battery of Leyden jars arranged to discharge over a spark-gap, F. The voltage across this gap could be measured by means of a Braun electrometer (not shown). R represents a Riess air thermometer, the reading of which is a measure of the amount of energy which passes into the line protected by the lightning arrester, A; the smaller this reading the better the protecting qualities of the arrester. N is a choking coil whose turns can be varied at will, and U is a mercury switch of which the two contacts, 1 and 2, are connected to the ends of one side of the arrester, so that by inserting the thermometer lead, *a*, into 1 the arrester is placed as a shunt to the circuit to be protected (equivalent to Fig. 1), and by placing *a* in 2 the "series" arrangement is obtained (Fig. 2).

The first tests were carried out with a single-plate hand-driven Töpler influence machine and a battery of five large Leyden jars giving a 6mm. spark about every 40 seconds. The jars were left permanently connected to the spark-gap (as in Fig. 3), and the slow changing up was found to lead to rather variable results. Later, a large 20-plate motor-driven influence machine with a battery of eight Leyden

* *Electrical Engineer*, vol. xxxiv., p. 7.

Digitized by Google

jars was used, and their sparks of 11mm. at regular short intervals were obtained. Before taking a reading with this latter machine, several sparks were allowed to pass to earth across the gap, F, through a separate earthing switch (the connections between U and F being broken), and then this earthing switch was opened, and the next spark allowed to pass through the arrester and the air thermometer. In this way the gap, F, was prepared by the sparks to earth before the actual reading was taken, and much more uniform results were obtained, the variations between successive readings under the same conditions not exceeding 5 per cent. The two series of tests gave qualitatively the same results, but differed a good deal quantitatively, the tests with the single-plate machine making the series arrangement appear even more favourable than those with the 20-plate machine. Variations in the applied voltage were produced by adjusting the gap, F, whilst variations in the quantity of electricity discharged were produced by charging the number of Leyden jars used.

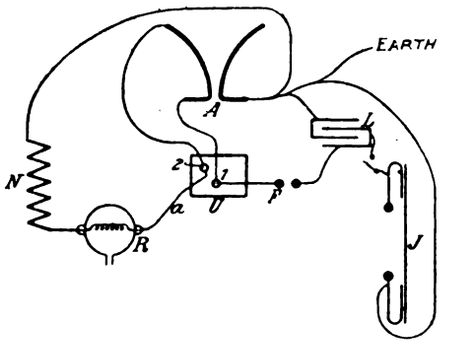

FIG. 3.

Seven different types of arrester were tested: (I.) telegraphic lightning arrester with ridged plates; (II.) Siemens and Halske horn lightning arrester; (III.) Allgemeine Elektricitäts-Gesellschaft horn lightning arrester; (IV.) Wurts roller lightning arrester; (V.) an arrester similar to (I.), but with smooth plates, the distance between which could be adjusted; (VI.) an arrester with bent smooth plates; (VII.) a horn lightning arrester similar to (II.), but fitted with flat sheet-metal horns, 2cm. wide, in place of the usual round wire horns.

The results of the various tests are collected below.

*Experiment A.*—To show the effect of varying the length of gap, F, and the effect of varying the number of Leyden jars in use, carried out with the single-plate machine. The

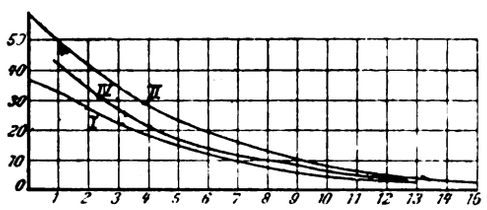

FIG. 4.

air thermometer reading with the shunt arrangement of the arrester is in each case taken as 100.

| Arrester No. | Length of gap, F, in millimetres. | Number of Leyden jars in use. | Relative reading on air thermometer with the series arrangement, calling the reading with the parallel arrangement 100. |
|---|---|---|---|
| I. | 5 | 4 | 57 |
| ,, | 4 | ,, | 51 |
| ,, | 3 | ,, | 55 |
| ,, | 2 | ,, | 57 |
| ,, | 5 | 1 | 52 |
| ,, | ,, | 2 | 55 |
| ,, | ,, | 3 | 52 |
| ,, | ,, | 5 | 54 |
| VI. | 6 | 5 | 45 |
| ,, | 5 | ,, | 51 |
| ,, | 4 | ,, | 50 |
| ,, | 3 | ,, | 52 |
| ,, | 2 | ,, | 49 |
| ,, | 5 | 1 | 41 |
| ,, | ,, | 3 | 44 |
| ,, | ,, | 5 | 46 |

These figures show that, within the range of the experiment, the relative effectiveness of the arresters is not appreciably affected by the voltage or the quantity of electricity discharged.

EXPERIMENT B.—To show the Effect of varying the Air-gap between the two sides of the Arrester.

| Arrester No. | I. | | V. | | II. | | III. | | IV. | | VI. | |

| 4 | — | — | 54 | — | 63* | 59 | 18* | 30 | — | — | — | 63 |

† A. Single-plate. B. Twenty-plate.

The readings marked with an asterisk are somewhat doubtful. The differences between the tests taken with the single-plate and the 20-plate machines are probably due to the difference in length of time taken to charge up the battery of Leyden jars in the two cases. During this interval the air-gap in the arrester undergoes changes which facilitate the breakdown, and thereby increase the relative advantages of the series arrangement. That this is the case is confirmed by the fact that when a small liquid resistance of about 300 ohms was introduced into the earth connection of the arrester, so as to delay the rush of current to earth, the difference between the series and the parallel arrangement of the arrester disappeared almost entirely. It also had the effect of greatly reducing the individual differences between the various types of arrester. It is interesting to note that when the liquid resistance was replaced by a small additional air-gap in the earth-wire no

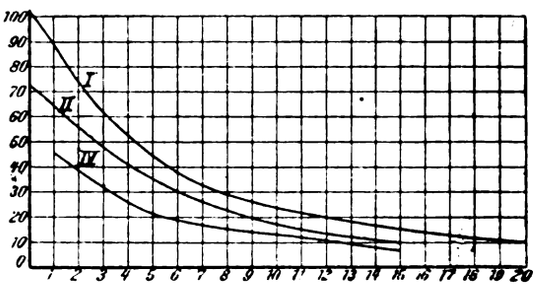

FIG. 5.

such effects occurred. It would seem, therefore, that for slow discharges the parallel and the series arrangement of lightning arresters are equally effective, but that for rapid discharges, such as those which cause the damage in practical cases, the series arrangement is much to be preferred. The insertion of a liquid resistance in the earth line, in order to avoid the risk of a short-circuit following a lightning discharge, is objectionable, the breaking of the short-circuit being more satisfactorily obtained either by employing a number of air-gaps in connection with a magnetic blow-out or by simply relying on the combined electro-dynamic and hot-air action in an ordinary horn lightning arrester.

*Experiment C.*—To show the effect of inserting choking coils between the line to be protected and the arrester (as at N, Fig 3), two choking coils were employed, consisting of spirals of bare wire wound on glass cylinders. The smaller coil had a cylinder diameter of 5cm. and a distance of 1cm. between successive spirals. The length of one turn was 17·5cm., of five turns 87·5cm., and of 20 turns 352cm. The larger coil had a diameter of 12·2cm. and a distance of 1·5cm. between spirals, and the length of one turn was 39cm. and of five turns 195·5cm. The smaller coil was sometimes used with an iron wire core. Figs. 4 and 5 show the results respectively with the large coil and with the small coil without iron core. The 20-plate machine was used for these tests. The ordinates give the air thermometer readings, and the abscissæ the number of turns in use. The numbers on the curves refer to the number of the arrester used. It will be seen that as the number of turns increases, the effectiveness of the arrester increases, at first rapidly, and

Digitized by Google

then more and more slowly. When an iron core was employed slightly fewer turns were required to produce the same result, but the improvement was not nearly in proportion to the increase in the self-induction coefficient, probably because, with the rapid fluctuation in use, the flux in the iron could not reach its full value. The figures show that equal lengths of wire in the two choking coils produce about equal effects. The writer considers that the effect of additional choking coils has been considerably over-estimated, for in practically all cases the apparatus to be protected already contains far greater self-induction than that of the choking coils added, so that the apparatus itself already causes the flat part of the curves (Figs. 4 and 5) to be reached where additional self-induction has little effect. This point was actually tested by employing an iron-cored choking coil permanently in the air thermometer circuit, and noting the effect of adding various numbers of turns of the above small choking coil. This effect, as might be expected, was practically negligible.

## THE ALTERNATING-CURRENT SERIES MOTOR.*

BY F. CREEDY, STUDENT.

(*Continued from page 845.*)

### APPENDIX II.

*On the Construction for the Efficiency of the Series Motor.*

The construction given in the paper for the efficiency of the series motor is only approximately true†, as may

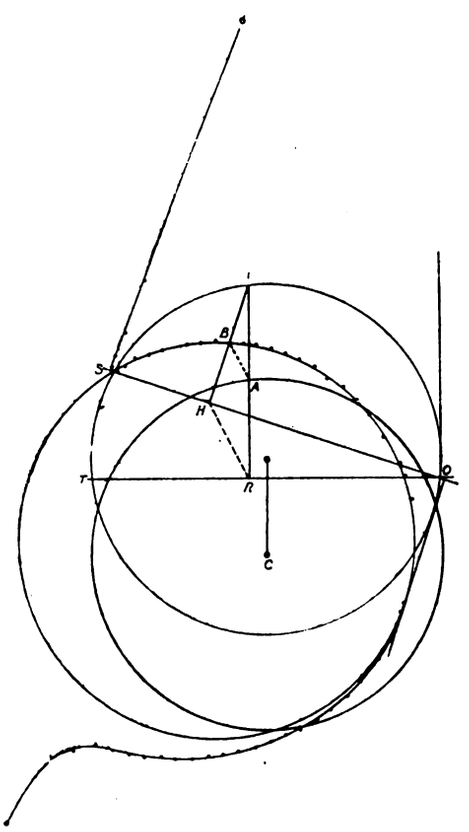

FIG. 16.

easily be seen by considering the case when O I = O T (Fig. 16). In this case I R is zero, but I H, the perpendicular from I on O S, is not zero. Therefore $\frac{I H}{I R} = \frac{I B}{I A} = \infty$ and the point B must move off to an infinite distance. Thus its *locus* cannot be a circle, but is a cubic curve as shown in Fig. 16. However, as the only part of the *locus* in which we are interested is the part corresponding to points on the current circle between S and the origin, it is worth while to consider whether this part is not sufficiently near to a circle for all practical purposes. Such a simple construction as the one under consideration should not be abandoned, without full investigation, in favour of constructions which, though exact, are far more complicated. In the first place, it is clear that if it be possible to represent that part of the *locus* in which we are interested by a circle, this circle may be drawn by the rule given in the paper. The *locus* obviously passes through S, and since the point B always lies upon I H (produced if necessary), the *locus* must be entirely contained between two lines parallel to I H and touching the current circle. Each of these lines will touch the *locus* at one point. Moreover, by suitably choosing the position of the point C (Fig. 16), the point B corresponding to any position of I may be made to lie anywhere on the line, I H. Thus *any* circle through S, touching a line drawn parallel to I H, and tangent to the current circle near the origin, will do.

A complete investigation, by the aid of the calculus of variations, into the difference between the actual *locus* and a circle described in this manner, would be far too complicated to be given here. However, it appears to be possible to show briefly that in all practical cases the curve does not differ much from a circle.

In one case the curve actually is a circle—viz, when O S coincides with O T. In this case the point B coincides with the point A, and its *locus* is, therefore, a circle of centre, C, and radius equal to that of the current circle. Thus we see that the nearer O S approaches to O T—*i.e.*, the greater the angle of lag of the standstill current—the nearer is the curve to a circle. Consequently, if we can show that when the angle of lag of the standstill current is small, say not more than 45deg. (and a motor having

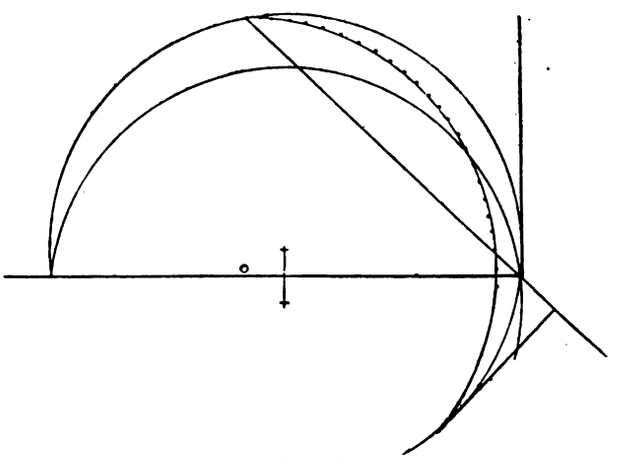

FIG. 17.

such losses would never be tolerated in practice), the curve is nearly a circle, it will follow that in all practical cases it may be represented by a circle. Anyone sufficiently interested may show for himself that, in such a case, the difference between the *locus* and a circle is barely perceptible. In Fig. 17 I have drawn out such a case as carefully as I could. It may be seen that the circle represents the *locus* of the points exceedingly well.

### APPENDIX III.

*Further Experiments on the Series Motor.*

The following appendix contains an account of some further investigations on the series motor. Since the investigations described above had rendered the method of designing an alternating-current series motor fairly clear, it was decided to endeavour to redesign the experimental motor, so as, if possible, to make it into a practical machine. The working out of the design from the constants of the carcase $p$, $p_1$, and $\nu$, which had been measured before, is given as an example above. However, as it had been decided to make a pair of slots in the pole-faces, and to put a compensating coil therein, this was rather a leap in the dark, as, of course, the slots and compensating coil entirely alter the constants of the carcase, and no means were at hand to estimate the effect they would produce. However, it was thought that if the motor was designed so as to be as good as possible with the unmodified carcase, it could not but be better when fitted with the compensating coil. A scale drawing of the shape of the stampings is shown in Fig. 18.

* Paper read before the Institution of Electrical Engineers.

† I am indebted to Mr. L. M. Rampal for pointing this out.

Digitized by Google

When the motor returned after these alterations had been made, the first thing done was to ascertain the effect of the slots on the constants of the carcase, first, before the compensating coil was put in, and, second, after it was in place. The following results were obtained as the mean of a number of observations of the impedance of the armature:

Before the making of the slots $\left(\frac{2}{\pi}\right)^2 p_1 = 60$ nearly.

After „ „ „ „ $\left(\frac{2}{\pi}\right)^2 p_1 = 48$ nearly.

After the compensating coil was put in $\left(\frac{2}{\pi}\right)^2 p_1 = 31{\cdot}5$ nearly.

Thus the effect of the slots and the compensating coil was practically to halve the impedance of the armature.

The compensating coil consisted of a single turn of $^{19}/_{14}$ cable passed through both slots, and the ends sweated up. As a result of making these slots, however, the leakage coefficient was slightly increased. The reason of this, of course, is that the slot increases the reluctance of the main magnetic circuit as compared with the leakage magnetic circuit. With a suitable design of the carcase—*i.e.*, a design in which the iron is disposed symmetrically round the armature so that none of the main flux need pass across the narrow neck at the back of the slot—this need not occur. Such designs of field magnet are the iron-clad type

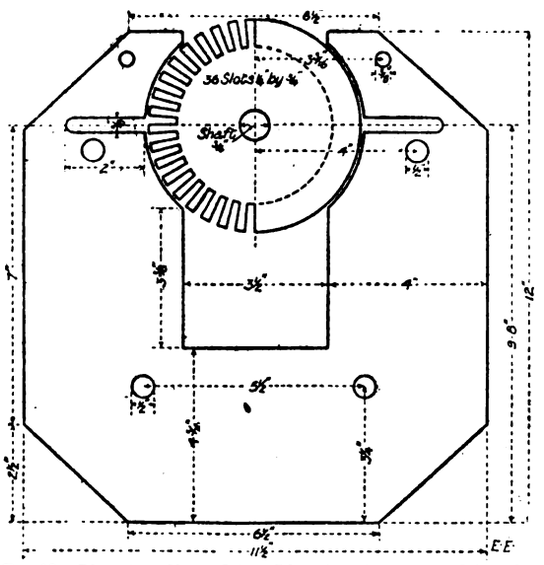

FIG. 18.—Diameter of bore, 5⅜in. Diameter of armature, 5¼in. Depth of stampings parallel to shaft, 3¼in.

or the ordinary multipolar type. By comparing the counter E.M.F. of the motor with the E.M.F. induced in the field coils, and also by means of direct experiments, it was found that the leakage coefficient, although it varied somewhat, averaged about 1·3. On account of the flux being alternating, its measurement was a very easy matter. A search coil containing 52 turns of fine wire was made, and solidly taped round. This made an extremely flexible coil of round section (¼in. diameter), which could be placed anywhere on the machine. If it be desired to measure the flux through a given area, it is only necessary to place this coil round the area; and the ratio of the E.M.F. induced in it to the E.M.F. in another coil of 52 turns wound directly over the exciting coil will be the ratio of the flux through the given area to the total flux. By means of this coil it was found that, as the mean of a number of observations, about 0·36 of the total flux passes through the part of the pole-face above the slot, and 0·41 through the part below. It was also found that by giving the brushes a lead in the direction of rotation, the leakage coefficient could be reduced slightly. With the aid of this flexible search coil, some leakage tests were taken during the progress of a brake test, the machine running under normal working conditions. It was found that the leakage coefficient did not vary much with the load, but remained constant at about 1·3. A considerable number of brake tests were next made in the endeavour to ascertain the efficiency, and also the effect on it of varying the number of field turns, of using different sizes of brush, etc, a direct-current shunt motor being used throughout as brake. It must be understood that the figures for the efficiency, given below, were not made to include the friction and windage of the series motor, since these present no features of special interest.

As a result of these experiments it was found that the efficiency was distinctly low. In the hope of raising it, experiments were tried with an increased number of field turns. It was found that above about 2,000 revolutions per minute the efficiency became practically constant at about 65 per cent. whatever the number of the field turns, the nature of the brushes, etc., though occasionally higher values were obtained, never exceeding 70 per cent.

The fact that increasing the number of field turns beyond a certain limit produces very little effect on the efficiency is very well illustrated by Fig. 19, which contains a number of curves in which the efficiency at various speeds is plotted against the number of field turns. These curves are derived from the same series of experiments on which Figs. 6, 10, and 11 are based. They show clearly that the efficiency at first rises quickly with the number of field turns, but soon ceases to do so, only increasing very slowly with increasing field turns. Before leaving these experiments it ought to be mentioned that the efficiency curve corresponding to 54 turns in Fig. 10 is almost certainly a good deal too high. During the test the output was so small that most of it was consumed by the friction of the two machines, and consequently a small error

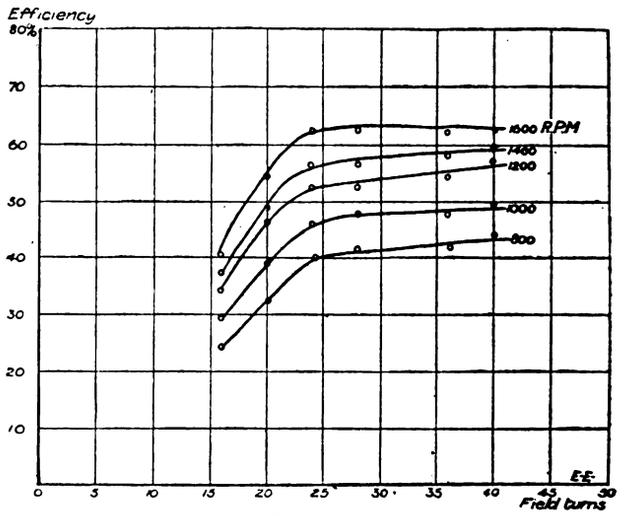

FIG. 19.

in determining this produced a large error in the efficiency. Fig. 15, the complete circle-diagram, also shows us the same thing as Fig. 19. As we increase the number of field turns, keeping the speed constant, the current vector will travel along one of the lines of constant speed. Now it can be seen from the diagram that for large values of $n$, the number of field turns, the efficiency lines, and the lines of constant speed are nearly parallel. Consequently, to obtain a given increment of efficiency, we must move a considerable distance along the speed line. Now, when $n$ is large, a given increment of $n$ only produces a small change in the position of the current vector, as the diagram shows. Thus, to obtain a given increment of efficiency, we shall have to make a very large increase in the number of field turns, or, in other words, the efficiency only rises very slowly with increasing field turns.

At the commencement of the experiments the motor was fitted with very broad brushes of hard carbon, covering about four segments. As it was feared that the large number of coils short-circuited under the brush might cause considerable loss, copper-carbon brushes covering three segments, and narrow brushes of very soft carbon covering one segment, were tried in succession. Neither of these produced any material effect on the efficiency, but perfect commutation was obtained with all three types of brush. It seemed as if the narrower the brush the softer the carbon allowable.

Thus, from these experiments, it appeared that the efficiency could not be raised much above 65 per cent. by

Digitized by Google

any modifications of field turns, brush resistance, etc. The next step appeared to be to ascertain the cause of this low efficiency. In order to do this an analysis of the losses occurring during a brake test was made in the three cases corresponding to 52, 84, and 104 turns.* This analysis was carried out in the following manner: Taking advantage of the fact that the same current flows through both field and armature, it is possible to read either the total input of the motor, or the watts given to the armature, direct on the wattmeter, according as the P.D. coil is placed across the whole machine, or across the armature only. The difference between these readings will be the field losses, which may thus be measured under actual running conditions during the progress of the test. The field losses could, of course, be measured by placing the wattmeter direct across the field, but as this involves taking readings at a very low power factor the above method is to be preferred. The field losses include the $I^2 R$ loss in the field, the hysteresis and eddy loss due to the alternation of the flux, and the losses in the coils short-circuited under the brush. The $I^2 R$ loss in the armature, the loss in the compensating coil, and any other stray armature losses, were measured in the following manner: Arrangements were made, by means of a two-way double-pole switch, for switching on either alternating or direct currents of equal magnitudes to the armature. The power consumed by each of these was measured on the wattmeter, and the difference taken as the loss in the compensating coil. The power consumed by the direct current is, of course, the $I^2 R$ loss only. By reading this on the wattmeter, we eliminate any error in the ammeter, or in determining the resistance. By switching on the field of the series motor while being driven by a direct-current machine, and noting the increase in the input of the driving machine, the iron losses due to rotation were measured. Lastly, by lifting the brushes and again observing the loss in the field when the current is switched on, we may separate out the loss in the coils short-circuited under the brush.

*(To be continued.)*

## JOHNSON AND PHILLIPS, LIMITED.

This long-established and well-known firm, it will be seen, is issuing further capital. We have known this concern most intimately for more than a quarter of a century, and throughout the whole of its life it has done exceptionally good work. It will be seen from the prospectus that the sole proprietor and remaining partner, Mr. Walter Claude Johnson, has been assisted gradually more and more till the incoming managing directors have been, during the last few years, carrying on almost the entire management of the business. When the inner history of cable work comes to be written, it will be found that the practical and successful laying and maintenance of submarine cables has been largely due to the perfection of apparatus supplied by Messrs. Johnson and Phillips. Probably almost every cable ship that has been equipped has had this equipment partly supplied by Messrs. Johnson and Phillips, and the work that they have done has been well done. From the commencement of what may be termed the electrical era Messrs. Johnson and Phillips have played their part in the construction of the apparatus for lighting and for power purposes, and, again, what they have done has been well done. The prominent part which they took in regard to the development of the arc lamp is also well known. We trust that under the new *régime* the works, carried on, as they will be, with continuity, will continue to produce the best apparatus that can be obtained of its various kinds, and will continue to be busily employed. We are quite sure that a firm possessing the reputation that this firm posseses will, under the new conditions, strive to retain and enhance that reputation. So far as values are concerned, the prospectus must speak for itself. The figures given are perfectly easy to read, and seem to us to indicate that as an industrial concern it will take a high place amongst those which have of recent years proved eminently successful.

* These analyses were all made at 25 frequency.

## HEATING BY ELECTRICITY.

BY H. ALLEN.

In the arts and crafts there are an exceedingly large number of processes in which the application of a high temperature is an absolute necessity, and a still greater number of cases where high temperature would be a source of considerable utility in reducing the length of time of many operations, as well as greatly facilitating many such operations as soldering, brazing, welding, melting, etc., if a convenient method of heat development was available at a reasonable cost. So far the electric current has not yet been exploited greatly in this direction, owing to the electric arc not being a suitable and convenient method for so many special cases, while the resistance method, when coils, etc., are brought into use as a heating medium, is subject to many inherent defects.

The resistance material called "Kryptol," consisting of a patented mixture partly composed of graphite, carborundum, silicates, and clay in a granular form, can be so readily handled by any ordinary skilled operator that a few details of its applications for such purposes as boiling, melting, etc., may be of service to many readers. The most simple form of apparatus (Fig. 1) may be described as consisting of a bed of refractory material having an electrode of carbon or other material at each end, to which the electric conducting wires are connected. These electrodes are situated some distance apart, according to the size of the stone, and the only further accessory that is required is Kryptol of proper sized granules to suit the available voltage of the current. If a quantity of "Kryptol" is spread, say, by means of a spoon, in a layer between the two electrodes, more or less current will pass through it in proportion to the thickness and width of the layer. For

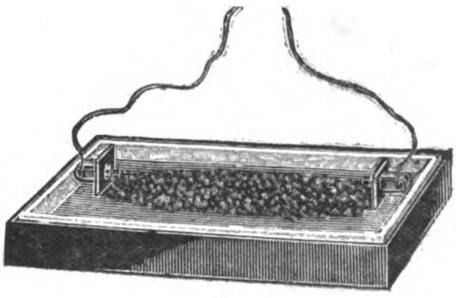

FIG. 1.

simply heating liquids, melting of lead solder and any metal of low melting point, the containing vessel may be simply laid on the bed of Kryptol. There are no regulating apparatus required to adjust the temperature, as all regulation is effected by manipulating the loose granules on the bed of the stone.

Supposing it was desired to weld two pieces of iron, in this case the pieces to be heated can be simply placed in the "Kryptol," while by thinning down the layer, or making it narrower, the heat rapidly rises to any desired temperature up to about 3,600deg. F. Another feature about this material is that it is made in different-sized granules to suit the voltage, the usual range being from 100 volts to 250 volts. In a simple test the writer melted a cube of copper weighing 8 45 grm. in one minute. The metal was contained in a small porcelain crucible resting upon the Kryptol, which had been brought up to the required temperature. The electric supply was at 240 volts, and 15 amperes were applied. This may not seem very economical in regard to cost of current, but a short time only is required to raise the temperature to a welding heat, and the current can be shut off immediately the required temperature has been attained. Several different forms of stones have been designed for use with this material, but the simple flat stone would be a great convenience for jewellers, dentists, chemical laboratories, etc.

**Trams Across the Bridges.**—At the meeting of the City Corporation yesterday the Court assented "to the bringing of tramways over a widened bridge at Blackfriars *or a new bridge*, subject to a satisfactory arrangement being *previously* arrived at with the London County Council as to cost, management, control, *construction*, and maintenance; and that the resolution of the Court of Feb. 2 last be varied accordingly," the italicised words representing the amendments.

### COMMISSIONS.

We have thought the time opportune to direct attention to this question of commissions. The whole subject brings us upon such delicate ground that it is difficult to handle. The general question is the only one that concerns us or our readers—special cases are altogether outside our purview. They cannot be touched except in a court of law, hence references must be without accurate definition of when, where, and whom. Business depends very largely upon commissions, and there is no suggestion of aught contrary to true business principles when commissions are given and taken under normal conditions. Many a traveller is paid partly or wholly by commission—and why not? That is certainly legitimate, and intended as an incentive to make the man work with energy. It is almost a necessity in many instances, because of the "human nature in man." We think Artemus Ward was wrong when he gave utterance to these words, and would prefer to think it "the artificial nature in man." The tendency of modern progressive civilisation is to make man lazy—to take away all natural desire to excel. There is little or no personal interest in making the work successful. The majority of workers are fully imbued with the idea that they are underpaid and overworked. Each thinks he ought to be a Carnegie and a Rockefeller rolled into one, without any of the early experiences of these men. Hence masters who have employment to offer have come to think that an honest wage does not necessarily bring about an honest day's effort, so the agreement purports to be "payment by results." Now there is one fact perfectly clear to all who have studied the question, and that is, payment by commission is scarcely or never payment by results. In numberless instances the true result is never known to the man who did the work in opening the account. But in a rough-and-ready manner the system may be passed. Some time ago the London Chamber of Commerce tried its hand in obtaining information about illicit commissions—commissions that cannot for a moment be accepted as necessary in true business, and which pertain really to the nature of bribes. One of our contributors has again brought up this question. He is evidently of the opinion that the strongest action should be taken to put a stop to such things, and so are we, but neither the London Chamber of Commerce nor any other body or individuals has suggested a method. Journalists cannot do it. A bald statement of fact—though after trial it may not be held to be libellous—often puts them to the expense of hundreds, if not thousands, of pounds to show it is non-libellous. Quite innocently a little time ago a journal said that an authority had authorised certain work to be done to supersede other work which had not come up to expectation. It was a mere statement of fact, but it involved a libel suit, and though the case was abruptly dismissed, we doubt if five hundred pounds will cover the costs to the paper. The cases as suggested by our correspondent are clearly of the illicit class. The latest phase which has been discovered legally is the Holborn case, though this is outside the category of those described by our correspondent. Practically, his communication hints that commissions are sometimes offered and sometimes received by consulting engineers. There can be no doubt, if the practice exists, it is bad. We trust that the suggestion even of its existence will meet with emphatic protest, and we have every reason to believe that the profession of consulting engineers is almost free of illicit commissions. There are black sheep in every fold, but the whole body of professional men must not be condemned for the actions of the few. Unfortunately, that view seems to prevail more and more, and when a unit is found doing something which cannot be commended, the man in the street is prone to tar a pro-

Digitized by Google

fession with the bad brush. The profession of a consulting engineer is one of responsibility. He is the expert advising the paymaster, and receives a recognised honorarium for his work. The successful man has no reason to complain of the honorarium. It is enough, and the whole body politic of paymasters expects to receive the utmost consideration from those who guard its interests. We trust there is no widespread giving or taking commission. Nor do we believe there is, and it may be that the publicity now given will lead all parties to enquire whether the tendency suggested to change professional etiquette is existent, and if it proves to be, to prevent further expansion.

## AT THE ARC WORKS.

The outing to Chelmsford which Messrs. Crompton and Co., Limited, arranged for Saturday last in connection with the Arc Works Club sixteenth annual athletic race meeting was unfortunately marred by the inclement weather, otherwise it would have been an unqualified success. A large party journed down from Liverpool-street Station in reserved saloons attached to the 10.55 train, and on arrival in Chelmsford were conveyed in brakes to the Arc Works, where a halt was made to inspect the different shops After all that has been heard of late about trade depression, it was refreshing to discover here an abundance of work. Every tool in the main shops seemed to be hard pressed. Perhaps the most interesting machines seen under construction were three generators destined for Calcutta. These generators are of the turbo type, and will be coupled to Parsons turbines. They combine some novel features, details of which must, however, be held over till a later date. Several large alternators were under test, and it was noticeable that Messrs. Crompton and Co., Limited, are doing a large amount of three-phase work. Motors of various standard sizes in process of wholesale manufacture were also much in evidence. Passing on to the instrument and lamp shops, which are quite apart from the main building, we noticed a similar state of activity. Here were potentiometers and their accessories, reflecting galvanometers, standard resistances, ampere-meters, voltmeters, and electric pyrometers in different stages of manufacture, and further on a number of switchboards in course of erection; also arc lamps, small fan motors, and projectors in great profusion. The fan motors represented part of an order for no less than 3,000 and the projectors an instalment of 600 for the Admiralty. With regard to the latter order, it is interesting to note that the Admiralty have at last abandoned the hand feed and are having all new projectors constructed on the automatic feed principle. We noticed a flame arc lamp and also a midget arc lamp burning steadily on test—representatives of types not yet on the market. It may be mentioned here that the lamp shop is undergoing considerable extensions.

The inspection over, an excellent luncheon was served in the employés' messroom. "Prosperity to the Arc Works" was proposed by the Mayor of Chelmsford. In his reply to that toast Colonel Crompton dwelt upon the success which had attended the efforts of masters and men to maintain the output and prosperity of the works, in spite of increased competition. After luncheon the brakes were again boarded, and a move made to the sports ground, which, despite a steady downpour of rain, tried to look gay with the aid of a plentiful display of flags and bunting. The afternoon was productive of some good sport under difficulties.

## ILLICIT COMMISSIONS.

[*Communicated.*]

Although the question of illicit commissions is a matter which has been ventilated by the technical Press on more than one occasion, the moral has never been pointed, or the tale adorned by the confession of any engineer who has acted as an accessory either before or after such criminal offence. This is not to be wondered at, but the unexpected does sometimes happen, as the following extraordinary story shows.

Quite recently a consulting engineer reported on the heating of a large building, and was asked to state his terms for preparing the necessary plans and for supervising the alterations recommended. In his reply to the authorities he stated that "he was prepared to give his clients credit for all commissions." His clients not unnaturally enquired what was meant by this statement. The engineer explained the giving clients credit for commissions. There are several ways in which work such as proposed is carried out. Either the authorities advertise for estimates on specifications made by the engineer, *in which case the successful contractor commonly hands the commission to the engineer to, what might be called, "lubricate" the work in progress Such commissions the engineer receives, but hands them over to his clients, as they would otherwise place him in a false position, and prevent his "jumping" on the contractor for bad work.* The other way of working, and which is far the better and cheaper way, is for the engineer to send out the specification and particulars, and receive estimates from the contractors. He is then put on trade terms with them, which are considerably lower than prices to authorities, and it is in this way that work is carried out. Practically, all engineering purchases carry a commission to the engineer—no doubt commercial immorality, but such is the custom, and a most objectionable one it is. Comment is superfluous! The statement that a successful contractor commonly hands a commission to the engineer may be at once stigmatised as a most scandalous libel on the general body of both engineers and contractors. The fact that it should ever have been made gives one furiously to think.

It is difficult to know what to admire most in this statement. The unblushing impudence with which the admission of the professional custom of accepting a bribe is made is only equalled by the virtuous manner in which forsooth the situation is saved by handing the spoil to clients. If ever an engineer under such circumstances is called in to carry out any engineering scheme, what a unique account must be sent in! Something on these lines presumably:

| | £ |
|---|---|
| Five per cent. commission on capital outlay ..... | — |
| Less — per cent. commission on capital outlay received from contractor ..... | — |
| Total ..... | — |

*O tempora! O mores!* What a shining example for the rising generation. Is it to go forth to the world, or even to a portion of it, that the members of the Institution of Civil Engineers and the members of the Institution of Mechanical Engineers "commonly" offer and accept commissions—*anglice*, bribes—to "lubricate" work in progress, and that while at least some of them do not approve of this practice, they continue to accept bribes and merely show disapproval by passing on such largesse to their clients? Is such a statement as this to be made to a public body, presumably in good faith, and to remain uncontradicted by the councils of the respective institutions concerned?

It may be that no one who knows would accuse the engineers of accepting such commissions for their own benefit, but they expose themselves to the gravest suspicions, and it is obvious cannot "jump" on any contractor after taking his money whatever its ultimate destination may be. How does the contractor know what becomes of his "peace offering" in such a case? Surely the engineer does not write to inform him that the money has been placed to his client's credit, and if he did, would the contractor believe him? The mere fact of any engineer receiving a present of any kind from a firm whose work he has to check on behalf of his clients, places himself hopelessly in the wrong. The aim of a consulting engineer, or of any other engineer who orders plant, should be, and in the majority of cases is, to get the most suitable machinery at the lowest price consistent with good workmanship and materials; all else is beside the mark.

The plain facts concerning the question of commissions

Digitized by Google

are these: No contractor offers an engineer a commission unless the latter first seems to hint that such tribute is within the region of practical politics, and no engineer of any position would dream of acting in such a way. If a commission is accepted—and this may occur in some isolated instances with men who have lost what little self-respect they ever possessed—its value is simply added to the total of the tender.

It therefore appears that an engineer who accepts commissions and hands them over to his clients, is only giving himself unnecessary trouble by going through a series of useless arithmetical operations assisted by the contractor. But how many men who once lowered themselves to take a commission would pass it on to their clients? Again, if a consulting engineer sends out specifications for work to be done under any public body, he is by no means put on trade terms. The greater part of the explanation is incorrect, in so far as it applies to the engineering business as a whole.

It will be instructive to notice the future action, or inaction, of "the powers that be," also to hear any further explanation for taking commissions to hand over to clients. Meanwhile, the most suitable motto for such cases seems to be:

"One hand stuck out behind the back, to signal 'bribe again';
The other on your dress-shirt front, to show your heart is clane."

## GLASGOW LOCAL SECTION OF THE INSTITUTION OF ELECTRICAL ENGINEERS.

The last monthly meeting of the present session of this section of the Institution of Electrical Engineers was held on May 9 at 207, Bath-street, Glasgow, Mr. R. Robertson being in the chair. Mr. P. D. Ionides read a paper on "Alternating-Current Motors in Industrial Service." The following is a summary of the paper:

Besides the growing recognition of the possibilities of the alternating-current motor, there were three factors which tended to make its use more general: (1) the increasing extent to which power was being supplied over long distances; (2) the growing popularity of the steam turbo-generator in private industrial plants; and (3) the new regulations issued by the Home Office for the use of electricity in mines. Alternating currents had been more generally adopted in America and on the Continent than in Britain, but the author was of opinion that the great municipalities and power companies in Britain would shortly offer alternating current for power purposes at a lower rate than direct current, for the reason that the converting apparatus for the former was less expensive. Before proceeding to describe some applications of the alternating-current motor, the author described at some length the best known types of this class of motor—*e.g.*: (1) The squirrel-cage polyphase motor, which consists primarily of the stationary parts carrying the windings, which receive current from the supply circuit, and the rotating part, which has no connection with the supply circuit. The stationary part is wound with coils similar to those used on the ordinary direct-current armature, while the rotating part carries the squirrel-cage winding, which gives its name to this type of motor. This winding consists of copper bars laid in the slots of the core, and connected at each end to heavy copper rings, the whole construction very closely resembling a squirrel-cage. The coils of the primary or stationary part, although resembling the coils of a direct-current armature, are connected in groups overlapping each other, so as to form a certain number of poles. The polyphase currents connected to these windings set up a revolving magnetic field. The speed at which this magnetic field revolves is dependent on the number of poles and the frequency of the supply—*e.g.*, at 3,000 alts., or 25 periods in a motor wound for four poles the magnetic field will revolve at 750 revolutions per minute. To determine this figure, divide the number of alternations by the number of poles with which the motor is wound. (2) The slip-ring motor, which differs from the squirrel-cage motor only in the secondary, which is coil-wound, the windings being connected to three slip-rings for starting with resistance in the secondary circuit. Once the motor is started, and the secondary short-circuited, its characteristics are similar to those of the squirrel-cage type. (3) The single-phase series motor, which is nothing more than a direct-current series motor constructed to operate satisfactorily with rapid reversals of polarity, in which the difficulties of commutation have been overcome by the use of compensating windings in the armature.

The squirrel-cage motor was used for all constant-speed work. It was very simple, both in itself and in its starting devices. The auto-starter consists of two auto-transformers mounted in an iron box with a double-throw four-pole switch. For starting, the switch is thrown to one side, connecting the line with the auto-starter, and furnishing current at a reduced pressure to the motor. After the motor has attained a fair speed the switch is thrown in the opposite direction, which connects the motor straight to the line. Motors up to 10 h.p., obtaining their supply from a 200-h.p. to 300-h.p. power station, could be started up direct without the use of an auto-transformer, but it was not advisable to do without the auto-transformer where the generating plant was of small capacity as compared with the motors, owing to the heavy rush of current taken by the latter at starting. A third starting arrangement was from a close-coil two-phase generator. The starter could be placed remote from the motor, which was a matter of great convenience. In regard to the starting torque, it is frequently stated that the squirrel-cage motor is incapable of starting up against full load. This is quite incorrect, for as much as three times the full-load torque can be developed at starting, while in the smaller sizes two to 2½ times the full-load torque can be developed; but, at the same time, the current to obtain such starting torques would be very heavy. To obtain a starting torque equivalent to full-load torque it requires, roughly, 2½ times full-load current in almost all sizes of motors, but as this requirement is only momentary it is of little consequence. For driving spinning machinery it is particularly suitable, by reason of the fact that within certain limits the speed is constant in relation to the speed of the generating plant, and independent of slight fluctuations in voltage. In spinning mills and such industries, it is of the utmost importance that all machinery should be started simultaneously. The squirrel-cage motor lends itself to this requirement very readily, as it is possible to leave all the motors in an installation connected direct to the line, and to start them all simultaneously by separately exciting the generator and then running up the engine. The squirrel-cage motor is particularly suitable for mining work, as there are no parts other than the bearings requiring attention, and the oil-immersed auto-starter, which can be made water and gas tight, needs no skill or knowledge in handling. In many pits where there are explosive gases, no other type of motor could be used with the same safety. For driving the lift turbine pump, which is becoming increasingly popular with mining engineers, a motor with a speed of 1,400 to 1,500 revolutions per minute is frequently required, and the squirrel-cage motor is particularly suitable in such a case.

For the driving of large haulages which must be started slowly and gradually, the slip-ring motor was preferable, the proportion of current to torque developed being almost similar to that for shunt-wound direct-current motors. For continual starting and stopping, the slip-ring motor possessed considerable advantages over the direct-current motor. The tramway type controller was generally used in each case, and while with the direct-current motor the currents broken by the controller were always at line pressure, with the slip-ring motor the currents broken were those in the secondary circuits of the motor and at a low pressure—a feature which added to the life of the contacts. Again, for electric braking the slip-ring motor could be used to great advantage by so proportioning the resistance in the secondary circuit with the first or second notches of the controller as to produce a gradual braking effect when the controller was reversed. That has been applied with marked success to a 150-h.p. slip-ring motor driving an endless haulage.

The requirements of variable-speed work (the making of

Digitized by Google

paper, printing, dyeing, etc.) were met by a small auxiliary motor driving the main motor through a worm gear and free-wheel clutch to give slow speed. The main motor is wound and connected to a controller of the tramway, so that the coils of the stator can be grouped to form eight poles for medium speed or four poles for full speed. It would be equally feasible to wind the moter with 12 and 8 poles to give three-quarter and full speed. A modified form of this arrangement can be used for the thriving of air compressors, hydraulic pumps, etc. In connection with work where it is necessary to have a speed of 6 or 8 to 1, the single-phase series motor offers a method which is simpler and more efficient than the direct-current apparatus. This method consists of a single-phase motor controlled by an induction regulator, which raises or lowers the voltage depending on the relative position of the primary which it moved in relation to the secondary by a worm-wheel and worm.

From the standpoint of the user, the author thought the alternating-current apparatus was probably the cheapest both in first cost and maintenance.

The following discussion took place:

The CHAIRMAN said that he was interested and surprised to find the author stating that the cost as well as the efficiency of the alternating-current motor was as favourable, if not more so, than the direct-current motor. The cost had always been one of the objections to alternating-current plant. It had also been generally believed that variable-speed work could only be managed with the direct-current motor.

Mr. H. A. MAVOR (Glasgow) said that, broadly speaking, the points raised in the paper were such as they could all cordially subscribe to. It was interesting to find that the polyphase motor showed signs of being only a passing phase in the development of the work, and that being so it did not emerge that there was any conflict between the continuous-current motor and the alternating-current motor, because the two machines were in all essential particulars alike. There was, however, a tendency to strain the argument in favour of polyphase plant, and the speaker felt he would not be justified in agreeing with everything which Mr. Ionides had said. The control of the polyphase motor was not a simple thing. It tied the user down to a specific speed much more closely than was the case with continuous-current plant. He could safely say that in all factories where polyphase machinery was being manufactured continuous-current motors were still used for a large number of purposes, because they were found more convenient to handle and easier to apply to a large number of details. The speaker regretted that Mr. Ionides had not made any mention of the use of alternating currents for traction work. The arrangement of generating three-phase current and transforming it down for traction did not seem a permanent solution of the difficulty, and if the experiments presently being carried out in America with single-phase plant for traction induced the people on this side to adopt similar plant, it would lead to a very interesting simplification of a difficult problem. The areas of distribution for traction seemed even in America to show signs of limitation. If it were the case that for distances of over 20 miles they must fall back on the steam locomotive, then the problem of distribution was less complicated than it was in some parts of America, where attempts had been made to deal with longer distances.

Mr. H. B. MAXWELL (Partick) said the paper was a particularly appropriate one in Glasgow, because he did not suppose there was any class of work where the polyphase motor could show to such advantage as in shipyard work. He thought the three-phase induction motor was most useful for extremes. He did not see that the complications required by the polyphase system were any more serious than those with a direct-current system. With regard to the single-phase series motor, nobody seemed to know anything about its capabilities and characteristics except the manufacturers, and he thought a guarantee of its good points should be taken when placing the order.

Mr. SPENCE (Alloa) said he approached the paper as a direct-current advocate. It would seem from the remarks of the author that in controlling a three-phase motor only the current on the motor was dealt with. He would like to ask if, in stopping a three-phase motor, the stator was always left alive on the line? The author stated that three-phase plant cost no more than direct-current plant. He had no doubt that must be a reference to manufacturer's costs, for he knew that it could not refer to the cost to the purchaser. He would like to know if Mr. Ionides considered a punching and shearing machine to be a constant-speed machine suitable for a slip-ring motor.

Mr. W. B. HIRD (Glasgow) said he was pleased to hear Mr. Ionides praising the squirrel-cage motor as contrasted with the slip-ring motor. He quite agreed with Mr. Ionides that the question of rapid variation such as can be obtained from a shunt-wound motor was often much exaggerated when the relative merits of continuous and alternating currents were compared, and the number of cases where a shunt control could give what was wanted were very limited.

Dr. J. B. HENDERSON (Glasgow) spoke at considerable length strongly in support of the alternating-current motor, and in the course of his remarks gave a very lucid description of the "Heyland" diagram, a detailed account of which, he said (in answer to a question), is not yet accessible in English.

Mr. IONIDES, in reply, said that Mr. Mavor had referred to the series motor as a possible means of doing away with the polyphase motor. The single-phase motor seemed to have its own particular field, just as the series direct-current motor had, and if Mr. Mavor could construct a motor of the squirrel-cage type without a commutator or slip-rings let him stick to it until he could get one without bearings. He had not dealt with traction, as it was out of the scope of his paper. He very cordially agreed with Mr. Maxwell, that people were apt to consider the variable-speed requirements of a few cases instead of looking to the constant-speed requirements of the great majority of cases. The loss in the alternating-current motor through variation of speed was very small compared to the cost of keeping a direct-current plant in a state of efficiency. One of the greatest advantages of electricity over steam plant was its low maintenance cost, and the speaker maintained this was a feature which was accentuated in the alternating-current plant. He agreed with Mr. Stevenson that, in regard to turbine pumps, it was not necessary to vary the speed. In regard to the slip-ring motor control, Mr. Spence wanted to know what happened to the primary circuits; whether they were left closed or not. They were not left closed, but at the time they were open the resistance in the secondary circuits was usually such as to make variations in the primary infinitesimal. The question of comparative cost was a very wide one. In actual practice, when it came to working the two kinds of plant side by side, the first cost was practically the same.

The results of the voting for office bearers and committee for next session were then announced as follows: Mr. John M. Munro (chairman), Mr. F. A. Newington (vice-chairman), Mr. E. G. Tidd (secretary and treasurer), Messrs. W. W. Lackie, E. T. Goslin, J. K. Stothert, J. Macfee, Sam Mavor, W. Stevenson, Blackwood Murray, J. Lowsen, A. W. Stewart (members of committee).

A vote of thanks, proposed by Mr. Lackie, to Mr. R. Robertson for his occupancy of the chair throughout the session closed the meeting.

## REPLY TO DISCUSSION ON MR. A. M. TAYLOR'S PAPER ON "STAND-BY CHARGES AND MOTOR-LOAD DEVELOPMENT."

Following is the full text of Mr. A. M. Taylor's reply to the discussion on his paper read before the Birmingham Local Section on Dec. 14 last, and presented at a later date in amplified form to the parent Institution. An abstract of the paper and a report of the discussion will be found in our issues for Jan. 13, May 5, and May 19 last.

In reply to the various speakers who have taken part in this discussion, there are four principal points on which the discussion has centered, and I think it will conduce to clearness if these points are, in most cases, referred to, rather than direct replies given to the various speakers. The four points alluded to are: (1) objection to departure from the ordinary methods of treatment; (2) criticism of the values taken for the diversity factor and the nomenclature adopted; (3) refusal to accept 1d. per unit as a bed-rock price for "interest-paying" loads; (4) difficulties suggested in the application of the restricted-hours' system.

In reference to (1), I would suggest that the method of considering things only from the station point of view is apt to lead to an overlooking of what goes on at the consumer's end of the line. My method, on the contrary, works back from the consumer to the station, and is less likely to overlook these points. The outcome of the discussion would seem to show that through confining investigations principally to the station, the important point has been overlooked of the very low load factor possessed by the average motor (I could adduce a prominent illustration of this). The diversity factor has been hailed as a sort of undeveloped gold mine, and no explanation has been given of the fact—indeed, I have nowhere seen it observed before—that the station load factor is, with a motor load, occasionally several times that of the motor load factor.

In reply to Mr. Arthur Wright, the principle adopted in the lower half of p. 3 of the paper is to split up the present charge per unit for management, etc., into two parts—viz.: a part which would be unaffected by taking on a large non-interest-

Digitized by Google

paying load (the station capacity remaining unaltered) and a part (such as the office staff) which would be increased almost in direct proportion to the number of consumers and hence to their diversity factor. The proportion of present charges which must be so divided up varies, of course, in different towns, but for lighting stations of 2,000 kw. it should not be materially different from what I have taken, and each engineer can determine it for himself quite readily. In further reply to Mr. Wright, the size of station is assumed constant at 2,000 kw. all through pp. 3 and 4, and the net profit is assumed to be a constant sum per annum.

In reply to Mr. Cooper, I have assumed that cost of land for generating station is included in the sum sanctioned by the Local Government Board, on which interest is paid. Depreciation should, it seems to me, be met out of net profit, where it is provided for at all.

In reply to Mr. Vignoles, I have not forgotten the cost of service connections. He will find them alluded to on p. 24 of the paper. His figures, too, are greatly over-estimated. He will find that 400 (not 5,000) customers of Class I. would account for 5,000,000 units; hence his figures are just 12 times too high. The actual cost of a service connection is about £2, and 7 per cent. on this would be only 3*s.*, which on a £25 bill per annum (5-h.p. motor) is almost negligible. No stiffening of mains has to be considered, on a restricted-hours' system, in most cases, hence I allow nothing for this.

As regards (2): The diversity factor considered on pp. 18 and 19 of the paper is the average value of the *true* diversity factor taken over a period sufficiently long, say for at least an hour, and sufficiently frequently (say at several different times of the week) to ensure a representative average for the class of load in the town. The method adopted in the paper of considering a cyclic load factor has, it appears, introduced confusion. This it might be well to avoid by omitting as far as possible all reference to any but the "annual" load factor of the motor, or that of the station. In the case considered the "cyclic" load factor has merely to be multiplied by the ratio of $\frac{49\frac{1}{2}\text{ (hours per week)}}{168\text{ (hours per week)}}$ = say 0·3, in order to convert it to the "annual" load factor. Thus, 100 per cent. "cyclic" load factor becomes 30 per cent. annual, and 25 per cent. "cyclic" becomes 7½ per cent. "annual," as they are designated in Table A. The statement that the diversity factor is the *reciprocal* of the cyclic motor load factor may then be altered as follows: the diversity factor is (in the limit) equal to the reciprocal of the annual motor load factor multiplied by a constant.

An example will make the case clear. Taking the motor load curves just published by Mr. Jeckell for Coventry (see the *Electrical Engineer* for May 17), and working out the diversity factor for each hour of a typical day, by dividing the kilowatts observed at station into the total kilowatt capacity of the motors connected (1,150 h.p. × ·85) = 980 kw.), we get the following values: 7 to 8 a.m. = 3·32; 8 to 9 a.m. = 3·16; 9 to 10 a.m. = 2·65; 10 to 11 a.m. = 2·08; 11 a.m. to 12 noon = 2·08; 12 noon to 1 p.m. = 2·20; 1 to 2 p.m. = 3·63; 2 to 3 p.m. = 3·44; 3 to 4 p.m. = 2·04; 4 to 5 p.m. = 2·0; 5 to 6 p.m. = 2·25; 6 to 7 p.m. = indeterminate; 7 to 8 p.m. = indeterminate. The average through the day is 2·62, but the true figures, when all the motors are on (if we eliminate the breakfast, dinner, and tea hours', is nearer 2·1.

Now, units per brake horse-power installed per hour of working

$$= \frac{\text{236 units per B.H.P. per quarter}}{\text{say, 13 hours} \times 5\frac{1}{2}\text{ days} \times \text{13 weeks}} = 0\cdot254\text{ unit per hour}$$

(0·3 unit if we take 11 hours per day).

"Cyclic" load factor

$$= \frac{0\cdot254\text{ unit}}{(1\text{ h.p.} \times \cdot85) \times 1\text{ hour}} = 0\cdot299 = \text{say, 30 per cent.}$$

$$\therefore \text{Diversity factor (my method)} = \frac{1}{\frac{30}{100}} = 3\cdot3\text{ (in the limit).}$$

Hence for a diversity factor of 3·3 (in the limit) the *observed* diversity factor = 2·1 (with all motors on), and I therefore accept Mr. Arthur Wright's suggestion that in taking 1·5 as the average for a limit of 4, I have done injustice to the electric motor. It should be nearer 2·5 for a motor having a 7½ per cent. annual load factor, as per my Class II. The annual load factor at Coventry works out to about 12·7 per cent. (236 units per brake horse-power installed per quarter).

Now compare the above with Mr. Tapper's figures for Stepney:

Units per brake horse-power installed per hour of working

$$= \frac{\text{113 units per H.P. per quarter}}{\text{say, 13 hours} \times 5\frac{1}{2}\text{ days} \times \text{13 weeks}} = 0\cdot122\text{ unit per hour.}$$

"Cyclic" load factor

$$= \frac{\cdot122\text{ unit}}{(1\text{ h.p.} \times \cdot85) \times 1\text{ hour}} = \cdot143 = 14\cdot3\text{ per cent.}$$

$$\therefore \text{Diversity factor (my method)} = \frac{1}{\frac{14\cdot3}{100}} = 7\text{ (in the limit).}$$

Hence it is easy to understand how it is that Mr. Tapper gets 4·4 for the observed value of his motor diversity factor. The annual load factor at Stepney works out to 6·1 per cent. (113 units per brake horse-power installed per quarter).

The two above examples, covering largely different classes of load, appear to me to fully corroborate the deduction that diversity factor varies inversely as load factor of motor. As a further proof I suggest the following considerations.

In the *traction* examples cited below the product of diversity factor and motor load factor (annual) and the observed station load factor are given in parallel columns.

| — | Theoretical station L.F.* | Observed station L.F. | Motor L.F. | Observed D.F. |
|---|---|---|---|---|
| | Per cent. | Per cent. | Per cent. | |
| Wolverhampton... | 34·6 | 34·4 | 11·9 | 2·9 |
| Liverpool ..... | 47 | 46½ | 12·5 | 3·75 |
| Glasgow ..... | 40 | 35 | 5·7 | 7·0 |
| Sheffield ..... | 37 | 45 | 8·8 | 4·2 |

* Product of motor load factor and diversity factor.

I venture to suggest that these figures bear out the statement which Mr. Arthur Wright disputes—viz., that there is any relation between the diversity factor of a motor business and the station load factor. I think it has not been sufficiently emphasised in this discussion that it is not the combined diversity factor of motors and lights (taken over a mid-winter "peak" load of at least an hour's duration, so as to take the full overload capacity of the plant) which is the divisor which should be used in obtaining interest charges per kilowatt of consumers' maximum demands. The diversity factors of lights and motors during this period are capable of being, and should be, determined separately and used as divisors for obtaining interest charges. I wish to point out that the motor diversity factor will vary considerably according to whether the combined "peak" occurs before or after 5 p.m., and this again will depend on the class of lighting load in the town, whether shops and offices on the one hand, or residential on the other. We all owe a great debt to Mr. Wright for his masterly enunciation of the fundamental principles of economical supply in days when it was not generally understood, and it is a source of much gratification to me to receive from him such an eminently fair criticism on these points, though I regret we seem to agree to differ on the "diversity factor" question. I think he will see, however, that the final sentence of his reply is directly contradicted by the results at Coventry, which were 2·08 before lunch and 2·04 after it.

We now come to (3), and in reply to this I would say: nobody has indicated how we are to charge a "bed-rock" price of anything less than the 1·45d. per unit of my Table A in a small station of 2,000 kw. capacity except by a possible reduction of 0·25d. on the works cost. This latter would be justified if the load were *exclusively* a motor load. As, however, there will always be a fair proportion of lights as well, so there will *always* be a "peak," and stand-by charges will be incurred in boilers and pipework, etc., which would be avoided on the restricted-hours' system. It would seem that engineers are, for the most part, counting on the "diversity factor" to reduce their capital costs and stand-by charges. One of the speakers even goes so far as to divide his "stand-by cost" by the aggregate kilowatts of the consumers' motors, and then *again* by the diversity factor, which in the case concerned has a value of 4. This is equivalent to taking account of the diversity factor twice over, and making the stand-by losses per kilowatt just four times too cheap! Other engineers, I believe, do the same. What is the result? The lighting consumers have to pay the piper! This is the only way the station is saved from bankruptcy.

The point I wish to emphasise is this. Take a station, as in Class I. of my Table A, where the motor connections aggregate 2,000 kw., there being no lighting, and the station load is also 2,000 kw. all day long (nine hours). Surely nobody will deny that here, at least, the diversity factor is unity. On such a station interest charges will come to 0·45d. per unit. If now, instead of this, we take Class II. of motor, and if the diversity factor—which, let us assume for the sake of argument, varies inversely as the motor load factor—were to reach its limiting value of 4, in a station consisting (exclusively) of motors of this class, the interest charges per unit would be the *same* as for Class I., excepting that part relating to mains and service connections, the latter of which would, of course, be raised fourfold. But, by however much the diversity factor may be short of the theoretical limiting value at times of maximum load on the station, by that amount will the interest and other stand-by charges (per unit) be *greater* than for Class I., and it has to be borne in mind that the smaller the average load factor of the

Digitized by Google

motors the greater is the amount by which the diversity factor falls short of the theoretical limit for the motors only. That this must be so will be apparent when we consider that for a "cyclic" load factor of 100 per cent., the "limiting" and the "observed" values of the diversity factor must coincide, each having a value of unity. When, in addition to this, we have a lighting load superposed on a motor load, the resultant diversity factor (at the time of peak load) is much less, and the increase of the station load factor is not, I anticipate, in the same proportion as the decrease in the diversity factor (though I have not, as yet, completed investigations on this point). Hence the interest charge where the motor load factor is, say, only 4 per cent., as at Sunderland, will be much nearer 0·75d. per unit than the figure of 0·45d. given by me for Class I., and higher still if we take account of the extra cost for services and mains.

As regards the items for management and office expenses, rates, and taxes, etc., it is surely obvious that, if diversity factor is inversely proportional to motor load factor, we require four times the office staff for a change from Class I. of motor to Class II., and hence the "office" charge per kilowatt of motors connected is constant, and must *not* be divided by the diversity factor to obtain the annual charge per consumer's kilowatt, while the "office" charge *per unit* will be quadrupled (the station output and load factor remaining as before). Again, if it be once granted that diversity factor varies inversely with motor load factor, it follows that for a station of a given kilowatt capacity the charge for management and technical staff (including the outside consultant if there is one) may be divided by the diversity factor to obtain cost per consumer's kilowatt, but the cost per unit remains unchanged, as the aggregate number of units sold, with a change from Class I. of motor to Class II., will be unaltered. Strictly speaking, it will be somewhat increased, as the limiting value of the diversity factor is less closely approached. Similar arguments applied to rates and taxes and net profit charges have been duly weighed by me in framing my Table A, in which, I submit, the only uncertain element is my estimate of 1·5 for the diversity factor for Class II.; which, in view of the Coventry analysis, I now agree to raise to 2·5. All things considered, I think that the onus of showing how current can be supplied for motive power at a lower rate than 1d. per unit from an average municipal supply station, except on a restricted-hours' basis, still rests with my critics and not with myself.

With reference to (4), there are no doubt difficulties in the application of the restricted-hour system, which, however, even in its most unattractive form seems to have been an unqualified success in Montreal, Brighton, Wednesbury, and numerous smaller towns, and, if we may judge from Mr. Vignoles's remarks, it has been successful at Grimsby in capturing motor loads, while I understand that at St. Pancras and in the stations of the County of Durham Company it is also being tried; but with what results I do not know. The question as to whether it will prove a success or otherwise seems to me to depend largely, if not entirely, on the prices that can be offered. Hitherto nothing less than 1d. has been offered, but if my figure of 0·54d. per unit (see Table A) can be justified, the arguments adduced on p. 10 of my paper should weigh with factories and other consumers having a good load factor. Where accumulator substations are warranted in a district, these would form a valuable supplement to the restricted-hours' system, and practically put it on all fours with an interest-paying load.

According to Mr. Snell, of Sunderland, the capital cost of accumulators and accessories for a sub-station of 2,000 kw. capacity is only £3 per kilowatt, and the maintenance of the cells under such conditions can be undertaken at 5 per cent. per annum. No doubt there are extra costs in connection with stiffening the mains locally, telephone connections to the main stations, cost of the sub-station building, etc., which will increase this total somewhat, and in the running cost there is the item for wages. All these, however, added together would probably not amount to more than from 0·1d. to 0·2d. per unit; which would give a figure of 0·65d. to 0·75d. per unit for the total cost. Such a combination would practically place the restricted-hours' supply on equal terms with interest-paying motor loads, as far as the convenience of the consumer is concerned, and would, in addition, give the former an advantage of at least 0·25d. to 0·35d. per unit. Such a difference would, in the case of double-shift (continuous) motor loads, be in many cases sufficient to turn the advantage in favour of the electric motor.

The suggestion to use batteries scattered about in small groups on the premises of isolated consumers was made by me to meet the case where sub-stations were not warranted, or where station engineers were not favourably disposed towards their adoption for the purpose of meeting the peak load. It would, of course, be futile, unless means could be devised for protecting the batteries from damage by the ignorance or carelessness of the consumers, and unless the battery makers themselves were prepared to find the capital for and maintain batteries under such conditions. This, however, I have reasons for believing to be the case. With motors of Class I., a 10-h.p. motor working two shifts could be supplied with current at only 0·12d. per unit above the restricted-hours' charge, this figure covering all charges for interest and maintenance of cells, charging dynamo, etc. For a day load only, the charge would be 0·25d. per unit. It will thus be seen that there is not much to choose between a battery sub station and private installations of batteries, while the latter offer an incentive to the outlay of private capital, and meet the case of scattered consumers in small towns where batttery sub-stations would be unjustifiable.

Mr. Gaster asks me to specify some of the uses to which the restricted-hours' system can be put. In reply, I have to say that the Dominion Cotton Mills at Montreal have 3,590 h.p. working on this system, employing motors of 300 h.p., 200 h.p., 100 h.p., and smaller capacities; the Montreal Steelworks take 175 h.p. in small motors in 15 h.p. to 20 h.p.; the Wire and Cable Company have a 300-h.p. motor; the Oil and Cloth Company, two 200-h.p. motors; the Cement Works, 300 h.p.; and the Water and Power Company, 350 h.p. for pumping purposes. In this country they have at Brighton some 300 h.p. in motors, ranging from 30 h.p. downwards, used in breweries, mineral water factories, laundries, printing works, stone-polishing and sawmills, ventilating motors, etc. An investigation of the average number of units sold per brake horse-power installed per quarter taken over the principal towns of the kingdom will, I believe, be found to show that the average load is only a quarter of the rated load as taken for Class II. of my Table A. It follows that the statements on p. 2 of my paper are correct, and that if continuous loads are in the market electric power stations are not obtaining them in any quantity. Until it can be shown that power can be supplied to interest paying motors at less than 1d. per unit on a sound financial basis, it seems to me that the restricted-hours' system, supplemented by batteries, offers the only prospect to our smaller provincial towns of obtaining such motor loads, and until these are obtained bottom prices will never be reached, for the reasons set forth in the paper.

In reply to Mr. Jeckell, the fundamental difference between us is that he had obtained his brake horse-power hours in what, I submit, is a totally wrong manner. To properly compare them with my Table C most of his figures have to be divided by 4, when it will be found that there is no material difference between his figures and mine. I am sorry that through misunderstanding Mr. Jeckell's verbal question at Birmingham I confirmed him in a wrong impression.

In reply to Mr. Patchell's remarks regarding my Fig. 7, I think he will find it helpful to study Figs. 11 and 12 (especially the latter) in connection with Fig. 7, also the remarks in appendix. No doubt, however, the fault is partly mine in not supplementing for London the explanations I was allowed to give verbally during the reading of the paper in Birmingham.

Mr. Boot's remarks show that my figure of 0·45d. for works costs, on a restricted-hours' basis, is about right. But as he does not enter into other costs, I cannot say anything with regard to his suggested selling prices.

In reply to Mr. Dawbarn's remarks, I think this gentlemen will concede that, if the diversity factor is really inversely proportional to the load factor, the ampere-hour capacity of the private cells would, in the aggregate, be the *same* as that of batteries in a sub-station, though the maximum rate of discharge might be somewhat higher. The private battery method may be a horribly inefficient way of carrying out extensions into unpopulous districts, but in a similar case the use of small direct-current booster for long feeders in 440-volt supply, though equally inefficient, has often saved the refusal of customers where there was not enough demand to warrant a sub-station, whether of the high-tension or of the battery type.

## FORTHCOMING EVENTS.

## SOUTH SHIELDS ELECTRICITY ACCOUNTS.

From the accounts of the South Shields electricity department for the year ended March 31, 1905, it appears that the total expenditure on capital account to that date amounted to £151,838 Abstracts of the revenue account and general balance-sheet are appended.

REVENUE ACCOUNT.

| Dr. Expenditure. | £ | s. | d. |
|---|---|---|---|
| Generating expenses, wages, etc. | 2,602 | 16 | 1 |
| Maintenance of plant | 704 | 15 | 3 |
| Distribution expenses, wages, etc. | 255 | 10 | 0 |
| Rents, rates, and taxes | 864 | 14 | 3 |
| Management expenses, salaries, etc. | 1,735 | 10 | 8 |

## BURY ELECTRICITY ACCOUNTS.

From the accounts of the Bury Corporation electricity department for the year ended March 31, 1905, it appears that the total expenditure on capital account to that date amounted to £76,408. Abstracts of the revenue account, general balance-sheet, and statement of electricity generated, sold, etc., are appended.

REVENUE ACCOUNT.

| Dr. Expenditure. | £ | s. | d. |
|---|---|---|---|
| Generation of electricity | 2,331 | 16 | 0 |
| Repairs and maintenance of plant, etc. | 456 | 14 | 6 |
| Management expenses, salaries, etc. | 780 | 8 | 0 |
| Distribution of electricity | 472 | 8 | 1 |

| Sale of electricity, less discounts | 10,922 | 19 | 9 |
| Interest and specifications | 21 | 5 | 3 |
| Rent of premises | 101 | 0 | 0 |
| Trading account (profit) | 362 | 13 | 4 |
| Pupil's premium | 25 | 0 | 0 |
| | £11,432 | 18 | 4 |

## PERSONAL.

Sir John Wolfe Barry, F.R.S., K.C.B., has been elected to succeed the late Mr. James Mansergh, F.R.S., past-president of the Institution of Civil Engineers, as chairman of the Engineering Standards Committee, which post Mr. Mansergh had occupied since the formation of the committee in 1901.

The Bury St. Edmunds Town Council have accepted the resignation of Mr. L. P. Greig, borough resident electrical engineer. The Council have resolved that the present staff be given a trial for three months from July 1, and have increased the salary of the chief engineer and his assistant, and propose to engage an improver.

The Watford Urban Council have increased the salary of the engineers-in-charge, Messrs. Osborne and Hick, to £75 per annum, and the salary of their electrical engineer, Mr. J. R. Weston, to £150 per annum.

The Southport Town Council have increased the salary of their tramways manager, Mr. T. J. Kendrew, as from April 1 last, to £225 per annum, and by annual increments of £12. 10s. to the sum of £250 per annum.

On Wednesday week, the 14th inst., the staff at the Hammersmith electricity works presented to the chief engineer, Mr. G. Gilbert Bell, a handsome silver salver on the occasion of his marriage.

## CITY OF SHEFFIELD—PUBLIC LIGHTING.

**The following is the conclusion of the report of Mr. S. E. Fedden, manager, Sheffield Corporation Electric Supply Department, on the public lighting of the city of Sheffield:**

*The Electric Lighting of Side Streets and Unimportant Thoroughfares.*

In many towns the electric lighting of side streets and unimportant thoroughfares has been undertaken by the use of various forms of incandescent lamps placed in existing gas pillars and lanterns, in some cases with great success and a very considerable improvement in the thoroughfares so lit. It seems probable that a great impetus may be given to side-street lighting by the introduction of a really successful lamp of greater efficiency than the present carbon-filament lamps. Amongst many new forms at present being developed the "Tantalum" lamp appears very promising. It is much more expensive at present than the carbon-filament lamp, but not prohibitively so, and no doubt the price will fall rapidly when larger quantities are made. Its consumption of current for light given is little more than half that of the carbon lamp, and its life may be considerably longer. My tests, so far, bear out the claims of the inventors to an encouraging degree. The filament is made of a rare metal, and is very long, the principal result of these two conditions being that it is less sensitive to fluctuations in the supply pressure than the carbon lamp, a point of very great importance to both supply undertakings and consumers.

*Some Notes and Curves by the Reason Manufacturing Company on the Application of their Patented System of Reflectors for Side-Street Lighting and After-Midnight Lighting.*

In one important respect it is astonishing how little attention has been paid to the utilisation of the light of public lamps so as to concentrate the rays upon the roads and pathways, instead of dissipating them upon the sky. This defect has been apparent with electric as well as gas lighting, especially with the arcs which are left to disperse their rays upwards and in all directions, besides, in many cases, notably in the city of London, obscuring the light by the character of the thick glass in the lanterns, and casting more objectionable shadows where the light is most needed. The Reason Manufacturing Company, of Brighton, have introduced some excellent types of reflectors, which overcome the defects to which we have alluded. One of their latest and best developments is adapted for either small arcs, Nernst, or the ordinary incandescent lamps. Having two burners in each lantern, there are no shadows, and all the light is diverted by the reflectors into the direction where it is needed. They are dustproof, reducing the cost of cleaning to a minimum, and the lamps and internal fittings are readily accessible by merely unscrewing the top finial, removing the cover and exposing a 12in. opening in the globe. Another type is the double-bracket fitting, which is specially adapted for tramway poles or arc light columns, when arrangements are made for switching off the arcs at a certain hour, and substituting smaller candle-power lamps during the remainder of the night.

The question of distribution of candle-power in streets is so important that I reproduce the following diagrams and particulars, which are of much interest. It must be borne in mind that in street-lighting, unless reflectors are used, not only all the rays of light directed above the horizontal are wasted, but also nearly all the rays of light directed into that half of the lower hemisphere which is occupied by the houses or land adjacent to the path; in other words, that when using a source of light giving a practically even spherical illumination, the upper hemisphere and practically half of the lower hemisphere are wasted unless suitable reflectors are used, which means that, theoretically, the efficiency would be increased by 300 per cent. In practice the Reason Company's patented system of reflectors and globes increases the efficiency by about 200 per cent. Thus it will be seen that two 16-c.p. lamps, instead of giving a mean of 32 c.p., give a maximum of 80 c.p. and a minimum of 32 c.p., or a mean of about 60 c.p." Although considerable improvement can be effected by the use of reflectors, I should not be prepared to endorse to the full the statements of the Reason Company.

PUBLIC ARC LIGHTING IN VARIOUS BRITISH TOWNS AND METROPOLITAN DISTRICTS.

The report concludes with the description of what it is proposed should be done at Sheffield.

# LEGAL INTELLIGENCE.

## AN ELECTRIC CURRENT ACCOUNT.

### A Novel Defence.

In the City of London Court on Thursday, before Mr. Registrar Wild, a claim was made by the City of London Electric Lighting Company, Limited, of 1, Great Winchester-street, against William Henry Stoneman, of 45, Queen Victoria street, E.C., for the sum of 10s. 2d., balance of account for electric current supplied. The defendant paid a sum of 4s. 4d. into court, and said he was not indebted to the plaintiffs for the balance of their claim. He said upon his commencing to be supplied with current by the plaintiffs he paid a deposit of £1, upon which sum he was entitled to interest. The deposit was held by the plaintiffs for the purpose of meeting any unsatisfied account. The plaintiffs' representative put in an account which, he said, showed the amounts due and the dates of payments made by the defendant, and said that by Act of Parliament, when a customer entered into a contract with them for the supply of current, he had to deposit a sum of £1, and when an amount became due the plaintiff company's contention was that they were entitled to appropriate the deposit or part of it, after which appropriation the amount left ceased to be a deposit. The Registrar said he was inclined to think that the amount deposited by the customer was to be treated as a deposit for the whole period, and was to continue as such until the plaintiffs gave notice that it was no longer to be treated as a deposit. The deposit was made to secure the plaintiffs against bad debts, and if they got security they must pay for it in the shape of interest, which was provided for by the Act of Parliament. When the time came for the plaintiffs to strike a balance, and there was money due to the plaintiffs, then they were entitled to give credit for the deposit and sue for the balance. The plaintiffs' representative said their contention was that they had an exercisable lien upon the deposit while the account was running. The Registrar said that the Act of Parliament said that "the company shall pay £4 per cent. per annum during the time it (the deposit) remains in their hands." The plaintiffs' representative said that in 1902 they regarded the plaintiffs' contract as closed, but they gave no notice that they considered the deposit as closed. They were of opinion that the matter settled itself automatically. The Registrar said he saw there was a further payment by the defendant at that time of £1. This sum, the plaintiff's representative said, they regarded as a reinstatement of the £1 deposit. The Registrar said he was of opinion that the money had remained in the hands of the plaintiffs from the commencement as a deposit, and remained so still, and the defendant was entitled to be paid interest upon that deposit. Directly the plaintiffs chose to put an end to the contract and disconnected the customer, the plaintiffs could not get out of payment of the interest while they held the sovereign. The plaintiffs' representative said their original claim was £1. 10s. 2d., then they credited the defendant with £1, leaving the 10s. 2d. Under the Act of Parliament they were entitled to make a charge of 2s. 6d., the cost of disconnecting a customer by reason of the non-payment of his account. The defendant said he did not consider he was in arrear. The account at the time was only £1, and the plaintiffs had £1 in hand of his. The Registrar said that, strictly speaking, the plaintiffs might then have put an end to the contract, the defendant owing money and being in default. The plaintiffs' representative said they had waived the charge for the first disconnection in 1902. The Registrar was of opinion that the defendant was clearly liable to pay the disconnecting charge of 2s. 6d. The defendant was entitled to a sum of 3s. 4d. against the plaintiffs for interest, and there would be judgment against him for 2s. 6d. The plaintiffs' representative said that it was a novel defence for the defendant to raise at the last moment. All their other customers had accepted their version of the reading of the Act of Parliament, and they thought under the circumstances they should be allowed some expenses against the defendant. The Registrar said he could not allow the plaintiffs any costs. He had given them his version of the reading of the Act of Parliament. The case might

Digitized by Google

be an important one to them, and he should be happy to facilitate them in any way they liked.

# COMPANIES' MEETINGS AND REPORTS

## CHADBURN'S (SHIP) TELEGRAPH.

The seventh annual meeting of shareholders in Chadburn's (Ship) Telegraph Company, Limited, was held on Friday last at Liverpool, Mr. William Chadburn (the chairman) presiding. Particulars of the report appeared in our last week's issue.

The CHAIRMAN, in moving the adoption of the report and accounts, said that the new freehold works in Cyprus-road, Bootle, had been fully equipped with additional tools and also with modern machinery. The concentration of all the manufacturing work under one roof had resulted in greater efficiency and economy of working.

Mr. T. R PENNINGTON seconded the motion, which was carried unanimously.

A sum of £100 was voted to the directors, other than the managing director, for their services during the year.

Messrs. T. Bassnett and T. R. Pennington were re-elected directors, and Messrs. Pannell and Co. as auditors.

A vote of thanks to the directors and staff for their services during the year was passed.

An extraordinary meeting was then held, when the following resolutions were submitted: 1. "That the articles of association of the Company be altered by substituting for Article 48 the following article—namely: 'The remuneration of the directors shall be determined by the Company in general meeting, and such remuneration shall be divided among them in such proportions and manner as the Company shall direct, or, in default of such direction, as the directors shall determine. In addition to such remuneration, each director shall be paid out of the funds of the Company all expenses incurred by him when absent from his place of residence on the business of the Company, including travelling and hotel expenses incurred by him in attending meetings of the directors or of the Company.'" (2) "That all payments hitherto made to any of the directors on account of the expenses incurred by them in attending meeting of the directors or of the Company be and they are hereby confirmed."

Mr. A. W. BIRKETT, solicitor to the Company, having explained briefly the circumstances under which the resolutions were deemed desirable, they were moved by the CHAIRMAN, and duly seconded, and carried unanimously.

## KALGOORLIE AMALGAMATED.

An extraordinary general meeting of this Company was held last week at the Great Eastern Hotel, under the presidency of Mr. M. F. Armstrong, for the purpose of appointing further directors to make up the minimum number of directors prescribed by the articles of association.

The CHAIRMAN stated that he had just received a circular outlining a scheme of reconstruction of the Company, but, so far, the Board had had no opportunity of considering it. If it were the desire of the shareholders, a meeting would be called for the purpose of considering the whole position of the Company.

After a brief discussion it was agreed to adjourn the meeting for a month.

## DUDLEY, STOURBRIDGE, AND DISTRICT ELECTRIC TRACTION.

The report of this Company for 1904 states that gross receipts for the year amounted to £46,383, and expenditure to £35,252, including £500 placed to depreciation and renewals account, interest on debentures, cost of repairs and maintenance, and all other expenses properly chargeable against revenue, leaving a balance of £10,031. After deducting the dividend on the preference shares accrued to Dec. 31, 1904, and adding the balance of £343 brought forward from the last account, there remains an amount available for allocation of £5,374. The directors recommend that there be placed to reserve (sinking) fund £2,100, and after paying a dividend at the rate of 3 per cent. per annum on the ordinary shares, there remains to be carried forward £274. There has been added to capital account during the year £6,483, expenditure on additional cables and other necessary works. The negotiations between the Birmingham and Midland Tramways, Limited, and all other companies owning and working tramways in the district for joint working under one management referred to in the last annual report have been concluded, and since July 1 last this Company's undertaking has been worked as an integral part of the whole system of over 90 miles of tramways in the Birmingham district. Considerable economies, it is anticipated, will accrue from this arrangement, and the possibilities of through running and interchange of traffic should result in increasing the Company's revenue. A further amount of £25,000 4½ per cent. debenture stock has been issued since the closing of the account for the year, and the liabilities to the Birmingham and Midland Tramways, Limited, have been reduced.

## BABCOCK AND WILCOX.

An extraordinary general meeting of this Company was held last week, at Cannon-street Hotel, for the purpose of considering and, if thought fit, passing resolutions for altering paragraph 14 of Clause 97 of the articles of association, and for increasing the capital of the Company to £900,000 by the creation of 270,000 new ordinary shares of £1 each, to rank *pari passu* with the existing ordinary shares.

Mr. JOHN DEWRANCE presided, and stated that the directors proposed to make a distribution of 10s. per share, and to ask them to subscribe a corresponding amount in the new issue of shares, which would be allotted to them in the proportion of one new share for every two ordinary shares held.

Mr. C. A. KNIGHT seconded the resolutions, which were carried unanimously.

## ELECTRICITY SUPPLY FOR SPAIN.

The report of the Electricity Supply Company for Spain, Limited, for 1904, to be submitted at the meeting on the 28 h inst., states that the rent of 1,100,000 pesetas, receivable under the lease of the Company's undertaking in Madrid to the Compañia General Madrilena de Electricidad, has been regularly paid to this Company's bankers, and has been remitted to London, except such sums as were retained for interest and other payments in Madrid. Owing to the high exchange ruling during the greater part of the year, the rent has only realised £31,669, as against £32,122 in 1903. The average exchange for the year 1904 was 34·65 pesetas to the £, as compared with 34·25 pesetas in 1903 and 34·10 pesetas in 1902. The rate, however, fell considerably in the month of December, and has since been more favourable than for some time past. Including interest on investments and deposits and other receipts, the gross revenue for the year amounted to £32,359. After deducting debenture interest, interest on loans, income tax, and all other charges, amounting to £17,524, there remains a net sum of £14,834. Of this, £13,337 has been applied to the redemption of debentures, leaving £1,497, which, with £5,043 brought forward from last year, makes a balance on profit and loss account of £6,540, which the directors propose to carry forward. The appropriation of £13,337 out of the year's profits to the redemption of debentures is in accordance with the policy previously approved by the shareholders of devoting the money, which would otherwise be available for dividends, to paying off the debenture debt of the Company. At the same time, this is unavoidable, as, owing to the war, the state of the money market renders it inadvisable to make an issue of consolidated debentures. The liabilities in Spain have been reduced during the year by about £4,600, and are now reduced to practically the amount represented by the unissued preference shares. The sum of £761 has been charged to revenue in respect of the settlement of Government and municipal claims for arrears of taxes for the years 1892 to 1900. Debentures amounting to £13,400 have been paid off during the year. This includes £300 first mortgage debentures purchased by the Company and held as an investment; but in view of a recent legal decision that a company cannot acquire its own debentures without extinguishing the security, they have been written off this year in the books of the Company. The amount of the debentures to be redeemed during 1905 is £14,100. The investment in Spanish Government 5 per cent. amortisable stock has been sold, and has realised a small profit.

# NEW COMPANIES REGISTERED.

**Catania Electric Lighting and Tramways Company, Limited.** Capital, £1,000 in £1 shares. Object: to construct or acquire tramways, electric lighting works, plant, and machinery in Sicily or elsewhere, and to carry on the business of tramway proprietors, suppliers of electric light, electrical engineers, etc.

### Liens Registered.

**South African Lighting Association, Limited, London, E.C.**—Lien registered June 2, for £1,800 4½ per cent. debentures (renewals), part of £20,000 issued; no trustees; charged on the undertaking and all the real and personal property.

**Stanley Electric Carriage Company, Limited, Chelsea, S.W.**—Debenture registered June 3, for £625; holder, Major-General E. H. Sartorius, V.C., C.B., Old Swan House, Chelsea-embankment S.W; charged on the undertaking and all the property, present and future including the uncalled capital.

**Auto-Electric Rifle and Target Company, Limited.**—Issue on May 18 of £50 debentures, part of a series created Dec. 5, 1904, to secure £5,000, charged on the company's undertaking and property, present and future. No trustees. Total amount previously issued of same series, £2,900.

# APPOINTMENTS VACANT.

**Assistant** in installation department. See advertisement.

**Shift-Engineer Foreman.** Applications to Box S 92, *Electrical Engineer* Office. See advertisement.

**Electrical Engineer**, Handsworth Urban District Council. Salary, £350 per annum. Applications by June 30.

**Principal** of the Paddington Technical Institute, Saltram-crescent, W. Commencing salary, £500 a year. Applications to the London County Council by July 3. See advertisement.

**Various.**—Northampton Institute, St. John-street-road, London, E.C. Mechanical engineering department: drawing office and lecture assistant, full time, £120; pattern maker and instructor in pattern making, full time, £120; junior drawing office instructor, full time, £100; laboratory demonstrator for the engineering laboratories, full time; junior technical assistant full time; evening instructor in automobile work, two evenings per week. Electrical engineering department: junior technical assistant, full time; junior lecture assistant, full time. Applications by June 29. See advertisement in last issue.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Fregenal (Spain).**—The Municipality require tenders for public electric lighting. Tenders by July 3.

**Mazarron (Spain).**—The Municipality require tenders for public electric lighting. Tenders by July 5.

**Liria (Spain).**—The Municipality require tenders for public and private electric lighting. No date fixed.

**La Rambla (Province of Cordoba, Spain).**—The Municipality require tenders for public electric lighting. Tenders by July 1.

**Fulham.**—The Council invite tenders for extension of cables, feeders, etc. Tenders by noon on July 12. See advertisement.

**Cataquoxes (Spain).**—The Municipal Electric Light and Power Company require tenders for electric plant. Tenders by July 1.

**Orense.**—The Telegraph Department of Madrid require tenders for installation of municipal telephones at Orense. Tenders by 28th inst.

**Orense.**—The Telegraph Department at Madrid require tenders for installation and working for 20 years of telegraphs in Orense. Tenders by June 27.

**Leigh (Lancs.).**—Tenders are invited for the supply of one water-tube boiler for the electricity department. Tenders by July 1. See advertisement in last issue.

**Rosario de Santa Fe Argentine.**—The Municipality require tenders for the construction and working of electric tramways in the town. Tenders by July 30.

**Talavara de la Reina (Prov. Toledo).**—The Telegraph Department of Madrid require tenders for installation of municipal telephones at Talavara. Tenders by 30th inst.

**London.**—The London County Council invite tenders for two low-tension feeder switchboards. Tenders by 10 a.m. on July 11. Full particulars in advertisement columns.

**Flushing.**—Tenders are required for the construction of the permanent way for the electric railway, Middelburg-Vlissingen-Domburg. Tenders to the Walcheren Railways Company, Flushing, by June 24.

**Burton-upon-Trent.**—The Corporation invite tenders for the electrical equipment on the overhead system of about 1¾ miles of tramway (Contract No. 10). Tenders by noon on July 7. See advertisement.

**Brighton.**—The Town Council invite tenders for supply, erection, and maintenance of a 260-cell storage battery, having a capacity of 1,000 ampere-hours, at their power station, Southwick. Tenders by 10 a.m. on July 3.

**Stepney.**—The Electricity Committee invite tenders for the supply during the year ending June 30, 1906, of ampere-hour meters, demand indicators, and arc lamp carbons. Tenders by noon on 28th inst. See advertisement in last issue.

**Rotherham.**—The Corporation invite tenders for the supply and delivery of cable and meters according to their requirements between July 1, 1905 and June 30, 1906. Tenders by 25th inst. See advertisement in last issue.

**Stalybridge.**—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

**London, W.**—The Great Western Railway Company invite tenders for the supply, delivery, and erection of the following plant in connection with their electricity generating station at Park Royal: (Specification 18) pipework, feed and other pumps, tanks, feed heaters, water-softening and oil-separating plant, etc. Tenders by 10 a.m. on 26th inst.

### RESULTS OF TENDERS.

**Johannesburg.**—The Corporation have awarded Dick, Kerr, and Co., Limited, the contract for 30 miles of overhead equipment.

**Hammersmith.**—The Board of Guardians have accepted the tenders of W. J. Fryer and Co., of Bravington-road, Paddington, for electric wiring at £4,580, and for transforming apparatus at £1,061.

**Bracebridge (near Lincoln).**—The tender of C. Pullan, 57, King's-arcade, Bradford, has been accepted for the installation of fire alarms, telephones, bells, and tell-tale clocks at the Bracebridge Asylum.

**Walsall.**—The Town Council have accepted the tender of Messrs. Callender, Limited, for laying the wires for the extensions in Park-street and Cross-street and a cable in Buchanan-road and Portland-street at a cost of £254.

**Alternators.**—Messrs. Johnson and Phillips report orders for 350 kw. three-phase alternator, 96 r.p.m., for supplying power in large works in the Midlands; a 35-kw. combined set, direct-current, for power in a manufactory in Ireland; also two 200-kw. three-phase alternators, 120 r.p.m., for colliery.

**St. Pancras.**—The tender of the Sloan Electrical Company for the supply of carbons, etc., for the sum of £476. 19s., has been accepted. Also the tender of Facer and Co. for the supply of coal to the Regent's Park and King's-road power stations for a period of 12 months from July 1, 1905. The following quotations for the supply of cables for laying feeder mains from Tavistock-place sub-station to the Somers Town district have been received:

| | | | |
|---|---|---|---|
| Western Electric Company * | £1,265 | 14 | 8 |
| British Insulated and Helsby Cables | 1,293 | 17 | 8 |
| Siemens Bros. and Co. | 1,318 | 13 | 6 |
| Callender's Cable and Construction Company | 1,332 | 18 | 0 |
| W. F. Dennis and Co. | 1,343 | 14 | 0 |
| Henley's Telegraph Works Company | 1,361 | 8 | 0 |
| Electrical Company | 1,360 | 3 | 1 |

* Recommended for acceptance.

# BUSINESS NOTES.

## TRACTION.

**Mansfield.**—A successful trial trip has been run on the Chesterfield-road section.

**Hull.**—The Corporation have appointed a deputation of five to attend the tramways exhibition next month.

**Colchester.**—Tenders are to be invited for the construction of the track in connection with the extension along Military-road.

**Limerick.**—The East Clare Railway Company, Limited, have published notice of their intention to apply for sanction to construct a tramway in Limerick.

**Rhondda.**—The Board of Trade have held an enquiry into the suggested agreement of the Rhondda Urban District Council for the leasing of the proposed tramways to a syndicate.

**Glen Valley.**—The Chirk Rural District Council have decided to support the application of the tramway company for permission to increase the speed of their cars to 15 miles an hour.

**St. Helens.**—The strike of tram drivers and conductors continues, though the company are gradually introducing additional cars on the various sections, and a regular service is now maintained throughout the day.

**Halifax.**—The Corporation have decided to construct the line, referred to in our last week's issue, from Salterhebble to Calder at an estimated cost of £6,400. The line will be a double one, except for one short length.

**Metropolitan Railway.**—The test match at Lord's last week provided the company with an opportunity, which was utilised, of demonstrating the promptitude with which, as the result of electrification, they can cope with extra traffic.

**Newport.**—As one of the cars was proceeding round Clifton-place the other day it commenced to move backwards. After proceeding some 10ft. or 15ft. it came to a standstill, the automatic running-back brake preventer having come into action.

**New South Wales.**—The earnings of the tramways for the quarter ending March 31 show a decrease of £4,623, and the expenditure a decrease of £2,653. The tram miles run show a decrease of 94,188, and 830,119 fewer passengers were carried.

**North Dublin.**—The Rural District Council have passed a resolution to the effect that the "time has arrived for the tramway company to give facilities for travelling from the city to outlying districts, as Cabra, Castleknock, and Blanchardstown."

**Maidstone.**—To-day has been fixed for the Board of Trade enquiry to consider the Maidstone Light Railways Extension Order, recently granted by the Light Railway Commissioners. Several traders will attend to give evidence in opposition to the order.

**Batley.**—A cheque for £20,000 was signed on Monday at a meeting of the Electric Traction Committee of the Batley Corporation for the purchase of so much of the present steam tramway system as is within the borough. The Corporation will later sell their holding to the British Electric Traction Company, who are to electrify the system.

**Light Railways.**—The Board of Trade has confirmed the following order made by the Light Railway Commissioners: North Wales Narrow-Gauge Railways (Light Railway) Order, 1905, authorising the working and maintenance of the Moel Tryfan undertaking of the North Wales Narrow-Gauge Railway Company as a light railway, and other matters.

**Walsall.**—The Corporation have adopted the recommendation, referred to in our last week's issue, in regard to running over the Wolverhampton and District Electric Traction Company's line to the Market-place, Willenhall. The Corporation will extend their terminus at Willenhall so as to form a junction with the company's system, the estimated cost being £200.

**Belfast.**—Nearly half of the work in connection with the reconstruction of the tramway system is now completed so far as the relaying of the lines is concerned. The York-street section is almost finished, and the lines are being put down on the various roads in the section. This week the reconstruction of the Cavehill and Whitewell tramway was commenced by Messrs. J. G. White and Co.'s men.

**Colombo.**—The new type of car recently got out by the tramway company is eight-wheeled, mounted on bogie trucks, and will seat 54 passengers. The most noticeable improvement is said to be that for keeping out the rain without in any way interfering with the ventilation of the car. Another striking feature is the automatic lifeguard for picking up objects between the rails.—*Indian Engineering.*

**Glasgow.**—The Corporation tramways continue to show a flourishing record. There is a net profit of £93,257 on the past year's working. The gross revenue was £768,000, and the expenditure £387,000, while the sum of £153,000 was allowed for depreciation. Interest and other charges absorb £134,000, leaving over £93,000 net profit. Of this £68,000 is to be written off for special depreciation, and the balance carried to reserve.

**Oxford.**—At a meeting of the inhabitants the following resolution was carried unanimously: "That in the interests of the ratepayers it is expedient to postpone the purchase of the present tramway company's undertaking until the City Council has given to the public every information as to the best system of public conveyances that can be adopted to replace it and reliable details of the approximate cost of alternate schemes."

Digitized by Google

**Bournemouth.**—The Corporation have now taken over the Poole and District Electric Traction Company's lines, the sum of over £117,000 being paid for the undertaking. The construction of a new line from Bournemouth to Christchurch is being rapidly proceeded with, and before the end of the summer season it is expected there will be a service of trams from Poole to Christchurch running right through the centre of Bournemouth.

**Hythe.**—The Town Council have received a letter from Mr. Stephen Sellon stating that he is prepared to submited his proposals in connection with a tramway service through the town, and that he should be pleased to have an interview with the Council. An interview is to be given to Mr. Sellon after a deputation of the Corporation has attended the conference of the municipalities of the neighbourhood on the question of tramways.

**Kirkcaldy.**—The annual tramway report of the borough electrical engineer states that there is a net deficit of £1,575. 2s. 11d after paying all interest on sinking fund and depreciation charges. From this must be deducted a credit balance of £50. 13s. 2d. carried forward from last year. The traffic receipts advanced from £9,934. 18s. 7d. to £11,752. 19s. 9d., an increase of 18 per cent. The total number of passengers carried showed an increase of 31 per cent. To meet the deficiency the electrical engineer proposes a readjustment of fares.

**Carthagena and Herrerias Tramways.**—Mr. E M. Underdown, K.C., presiding at the meeting of this company, said that they had been unable to declare a dividend last year, and he could not say that the business had increased to an extent that would enable them to do so this year; but they had an accumulation of money carried over, and that enabled them to divide 2 per cent., or 4s. per share. Their prospects were more favourable. They had a very fair increase of business up to the end of May, amounting to nearly £2,000, and that had been earned without any perceptible increase in working expenses. The report was adopted.

**Middlesex Light Railways.**—Sir Francis Cory Wright, Bart., chairman of the County Light Railways and Tramways, on June 7 opened a further section of the County Council's scheme of light railways and tramways, extending from the Archway Tavern, Islington, to Whetstone, where it will eventually join the light railway proposed to High Barnet. About 10 track miles is the length of the section, which has been equipped on the overhead system. The double-deck cars are similar in pattern to those already running on the other lines of the county. Mr. H. T. Wakelam, M.I.C.E, the county engineer, designed and supervised the work.

**London United Tramways.**—The London United Tramways offer £300,000 4 per cent. first mortgage debenture stock, forming part of the authorised issue of the 4 per cent. debenture stock of the company, at the price of £98 per cent., to existing stockholders of the company only. The money is sought for further capital outlay on the construction of tramways, and the amount is fixed in accordance with the trust deed, which provides that any issue beyond the original issue of £825,000 shall only be made to the extent of 50 per cent. of such outlay after an equal amount shall have been first provided by calling up capital or from other funds of the company.

**Ipswich.**—The report for the past year shows that the passengers numbered 5,693,680, the car miles run 692,310, and the receipts from passengers, parcels, etc., £23,327. The average speed obtained, including standing times at termini, was 5·79 miles per hour. The number of parcels dealt with has been 639, yielding £6. 0s. 9d., the expenses of this department being £29. 13s. The number of parcels is slowly increasing. The rolling-stock now consists of 36 double-deck cars, each seating 50 passengers. The working expenses total £18,868, which the revenue exceeds by £4,521, but interest requires £4,079, and for repayment of loan £1,264 is needed. This leaves an excess of expenditure over income for the year of £822. 6s. 9d., and there was also a deficit at March 31, 1904, of £1,919. The Corporation have adopted the report.

**Folkestone.**—A petition is to be presented to the Board of Trade by the Corporation for sanction to an extension of time for the construction of the tramways. The Corporation now has under consideration the offers of two companies to construct tramways from the harbour through Cheriton to Shorncliffe Camp and Hythe. The Traction and Powers Securities Company proposes to put down the overhead system, and the National Electric Construction Company specifies the Dolter surface-contact plan. Each company offers to pay the Town Council £15,000 towards the expense which it has incurred in widening Cheriton-road and £1,200 to reimburse the Corporation in regard to the cost incurred in securing a provisional order to construct its own tramways. Under that order there is an agreement with the Earl of Radnor not to adopt the trolley system, and his lordship has refused to waive his objection.

**London and District Motor Omnibus Co.**—At the meeting of this company, Mr. A. A. Campbell Swinton, who presided, said that a very careful investigation as to the best type of motor omnibuses had been made, and in this connection the Board had had to keep in view what could be obtainable within a reasonable time, and which was the most economical vehicle to be had. A first order had been given for a number of motor omnibuses, and the greater portion of them would be built in this country. In order to expedite delivery, certain portions of the machinery had to be made in Germany. It was hoped that some of the vehicles would be running early in August. All further orders would be entirely placed in this country. The Board had received information about the takings of various motor omnibuses now running to the effect that they were exceedingly satisfactory. If the company's omnibuses did equally well their success was assured.

**Dundee.**—One member of the Corporation, undaunted by the result of the last *plébiscite*, which was adverse to Sunday running, proposes that another shall be taken. The accounts of the Corporation tramway department for the past year are of a satisfactory character. The receipts on all the routes, notwithstanding dull trade, exceeded the estimate. Some 12 million passengers were carried, which represents an increase of fully half a million on the preceding 12 months. The total earnings amounted to about £45,000. Deducting the working expenses, there remains a gross profit of £16,900. From this balance provision has to be made for interest, sinking fund, etc., absorbing about £11,000, and the balance of some £5,500 is to be allocated to renewal fund, depreciation, and suspense account. There will remain a surplus of £100 to be carried forward. The committee express satisfaction at the state of the finances, and the manager has been instructed to print and circulate details of the accounts for the information of members.

**Sunderland.**—The annual report of the Corporation tramways has just been issued. The report states that the permanent way, rolling-stock, and overhead lines are in an efficient condition. The receipts for the year ending March 31, 1905, were £64 293. The cars ran 1,495,685 miles, and carried 15,364 463 passengers. The figures for the previous year were: receipts, £62,506; passengers, 14,848 958; and miles run, 1 433,463. The gross profits were £24,727, as against £26,748, being 8 6 per cent. on the average capital outlay for the year. The decrease in gross profit is accounted for by an increase in rates, due to an increased assessment, and to the fact that the tramways are assessable in full for general district rate purposes, whereas previously they were assessed upon one-fourth, as is the case with light railways. The tramway department contributed £1,125 more in the shape of rates this year than last. The report draws attention to the fact that the receipts for the east-end route averaged 6d. per car mile. As the expenses of the whole system, including capital, depreciation, and renewal charges average 1·34 per car, while the car mileage on this section was 118,810 miles for the year, it is evident that the loss amounted approximately to £2 149 But for these facts there would have been a net balance of profit, after paying interest, sinking fund, and depreciation, of £3,822, which would have been appropriated to the relief of the rates as in former years. The report also states that several more covered-in double-deck cars will be available for the winter.

**Whitsuntide Receipts.**—The Whitsuntide holidays appear to have been something of a boom to the tramways in the North, where the weather was finer than that experienced in the Metropolis. The total receipts for the week from the Wolverhampton Corporation trams were £1,321. 8s. 4d., while no fewer than 258 684 passengers were carried. This result is the highest yet attained. During the week 60,000 more passengers were carried than in any previous week, and not a single accident happened to mar the record. Halfpenny fares appear to have been highly popular. At Leeds the returns from Saturday to Tuesday show an increase upon last year's takings on the corresponding days to the extent of £731. 19s. 4½d., the receipts this year totalling £5,551. It is calculated that something like 1,200,000 passengers were carried during the four days. At Bradford the receipts for the Tuesday constituted a record for one day. The total amount was approximately £1,450, as against £1,345 last year, and £1,439 on May 4 of last year, on the occasion of the Royal visit, which was the previous highest total. The receipts on Monday were £1,311, against £1,307 on the corresponding day of last year. For the two days the total receipts this year were £2,761, against £2,652 for the corresponding days of last year. At Huddersfield the receipts for the four days amounted to £1,391, an increase of £159. At Halifax the receipts on the Tuesday amounted to £653, as against £555 on the corresponding day last year. The receipts for Tuesday broke the record established on Monday, when the takings were £642, the previous highest being £614 on Whit Monday, 1903. At Sheffield the Corporation beat their Whit Monday record, the takings amounting to £1,157, against £1,096 last year.

**Tramway Fatalities.**—An enquiry was opened on Monday at the Bristol General Hospital into the circumstances attending the death of Benjamin Trelawney Coates, who was crushed between an electric car in Victoria-street, near the Neptune Statue. The deceased was driving a van in Victoria-street, and it appears that he attempted to cross the road in front of a car approaching the city. He evidently did not notice another car which was going towards Brislington until it crashed into the vehicle he was driving, causing him to be thrown between the metals, the car passing over and severely crushing Coates. Efforts were made to extricate the body, but it was 20 minutes before they were successful. The man was hastily driven to the General Hospital in the marine ambulance wagon, but on that institution being reached it was found that life was extinct. The solicitor for the company remarked that his clients wished to express their deep regret for the sad accident, and to add that they would give every possible assistance they could in making the enquiry a complete one.—An enquiry was held at Liverpool concerning the death of James Hinds, who expired from injuries sustained through a fall from one of the Corporation cars. A witness stated that the deceased, who seemed to be a steady man, boarded the car with about a dozen other men. When the car started there were four men on the platform. After proceeding about 50 yards, the car, in going round a curve, swayed, and deceased fell backwards off the platform. The conductor said that when the car started from the stopping station deceased was standing on the platform near the door with a pipe in his hand. He seemed to be undecided whether to go upstairs or inside, and while the turn was being made he toppled over into the road without attempting to save himself. The jury returned a verdict of "accidental death."

**Rating of Trams.**—The town clerk of Wakefield has addressed a letter to the various local authorities through whose areas the lines of the Wakefield and District Light Railway run, inviting support in a proposal to contest the refusal of the company to pay in full the district rate levied by the Corporation on the ground that they are entitled to be rated at one-fourth only by virtue of Section 211 of the Public Health Act, 1875. The Corporation contend that the light railway is not a railway within the meaning of the section, but if it be

Digitized by Google

so, then the company are not occupiers of land used only as a railway (*vide* "Swansea Improvement and Tramway Company *v.* Swansea Urban Sanitary Authority, 1892," 1 Q.B., 351). The local authorities are invited to appoint representatives to attend a conference to discuss the matter at Wakefield Town Hall on the 23rd inst. At a meeting of the Swansea Corporation Finance Committee, the assistant solicitor read a letter from the Swansea Tramways Company in respect of the rating of the new sections of tramways constructed under the Light Railways Act, which provides that the basis of rating of light railways shall be to the extent of three-quarters of the general district rate. The Wakefield Corporation had written asking the Swansea Corporation to co-operate in fighting a test case under precisely similar circumstances to those that had arisen at Swansea, with a view to getting the question settled. The Chairman said the chairman and manager of the company had agreed to pay one-quarter of the general district rate pending the result of the test case, and undertaking to pay the full rate if the judgment went in favour of the Corporation. Mr. Tutton said it would be wise to join with Wakefield if a reasonable number of other towns joined in the common cause. The Chairman said they could adopt the principle, but not bind themselves until they were in receipt of further information, and this was agreed to.

**Edinburgh-Queensferry.**—At a meeting of the Lord Provost's Committee of the Edinburgh Town Council on Tuesday, the memorandum of agreement between the Corporation and the Edinburgh and Queensferry Tramway Company relative to the proposed tramway from Edinburgh to Queensferry was under consideration. It was agreed to recommend that permission should be refused to the company to take their tramway to Princes-street over the Dean Bridge, but a conditional approval was given to the proposal that the lines might go from the west end of Princes-street by Belford Bridge. The Town Council, however, it is understood, favour most the idea that the electric tramway should pass from the Queensferry-road down Comely Bank-road, and have the same terminus there as the Stockbridge cable car, by which passengers would be carried to and from the city. A question is under consideration whether the Town Council should not construct the section of electric car line from the Comely Bank terminus of the cable car to the city boundary at Blackhall, so as to save an outside company coming into the city at all. The memorandum of agreement, however, contemplates the company coming into the city. The fifth clause provides that the part of the undertaking within the city shall be executed by the promoters to the satisfaction of the Corporation or their engineer. The promoters are to keep in repair so much of the street as lies within their rails and 18in. on each side of them, and there is a clause protecting the drains, etc. The ninth clause gives the Corporation power to say what system of electrical traction is to be used; the tenth prohibits the company from erecting their power station within the city or of selling electric power or light within the city boundaries; and the eleventh clause contains powers of purchase by the Corporation of the tramways in whole or in part upon specified conditions. There are clauses also dealing with running powers, workmen's cars, etc., and the company are to be bound to carry passengers for three miles beyond the city boundary at 1d. a mile. A special meeting of the Town Council was fixed for yesterday to further consider the matter.

**Australia.**—We extract the following notes from the *New South Wales Budget*: Instructions have been received by Mr. L. Waxman, solicitor for Mr. A. E. Morgans, the promoter of the Essendon and Flemington (Victoria) electric tramway and electric lighting scheme, to place the necessary work in the hands of Messrs. Noyes Bros., of Queen-street, representing Messrs. J. G. White and Co., Limited, electrical engineers, London. Operations will be proceeded with immediately, and the power-house will be erected on a site purchased in Mount Alexander-road, on the property known as Glass's estate. The tramway will consist of two arms, diverging from the Flemington Bridge, one running past the Flemington racecourse to the Saltwater River, and the other along the Mount Alexander-road, past the Essendon Town Hall, to the junction of Bulla and Keilor roads. The cost of the whole work will be about £120,000. The machinery has been shipped, and the engineer in charge has left London for Australia. Mr. Bradford, electrical engineer, has furnished the Premier with his estimate of the proposed electric tramway from St. Kilda to Brighton, in length three miles. The estimate for the track is £18,965, and £4,750 for the cars—a total of £23,716, or £216 in excess of the amount authorised by Parliament. The Premier has given Mr. Bradford instructions to proceed. Speaking at the opening of the tramway from Hampton to Perseverance (Queensland), the Premier said that the Government were taking means to make land available, and one of the means of doing it was the construction of light lines of railway to districts where there were large areas of unalienated Crown lands. This was rather a new principle in railway construction. Hitherto it has been held that a railway must not be built until all the land was taken up and population had preceded it. There was no direct return secured from the land towards the cost of construction. It was undoubtedly true that the best of the lands in the coastal districts had passed into the hands of private owners, and if the Government built railways in a majority of cases it would be to lands with which the Crown had already parted, and from which they could get no direct return. He was trying the policy of building lines to districts where there were areas of Crown lands not available for settlement because it would not pay people to occupy them and transport the produce, say, 25 miles over black soil plains. The thing was to build the railway and arrange to get the price of the land and sufficient to pay for the railway. That was a sound policy. Even at the enhanced value the lands would be more valuable to the people taking them than if they selected otherwise.

**Grimsby.**—The following are particulars of the extensions agreed upon between the Corporation and the company, as described in a letter from the secretary of the company: (1) The company would be prepared to extend the present tramway line at the Park terminus for a distance of about 300 yards along Welholme-road West to a point near the Great Northern Railway level crossing. The line to be a single line with a passing place at Farebrother-street. (2) The company would be prepared to extend their present tramways in Hainton-street to Weelsby-lane, but would suggest that, in place of taking Hainton-avenue, the tramway should deviate into Welholme-road East and thence into Heneage-road. (3) The suggestion of a tramway extending from the Park terminus into Ainslie-street and Wintringham-road, and connecting up with the tramway in Hainton-street, could not be realised, as double-deck cars would not pass under the railway subway. (4) The company would be prepared at some future date to consider the desirabily of an extension in the direction of Stanley-street and Grant-Thorold Park, joining up with the Hainton-street tramways *via* Patrick-street East or other convenient thoroughfare. If the Sub-Highways Committee should regard this extension as one that should be considered at some period between the next three to five years, it appears to the directors that it would be unwise to construct the extension from Hainton-street into Heneage-road beyond, say, Patrick-street. If this were agreed, it would be feasible for the cars to run in a circle from the top of Freeman-street to Riby-square, *vid* Hainton-street, Heneage-road, Patrick-street, Durban-road, Stanley-street, and Cleethorpe-road. The company would be prepared to apply for powers and to construct the tramways under the following conditions: (1) No extra rent to be charged. (2) No increase in fares. (3) In the event of the Corporation exercising their right of purchase in 1921 of the existing tramways, the company shall sell and the Corporation shall purchase as a going concern, and according to the provisions of the Land Clauses Act, all extensions which may be constructed under the present agreement. After 21 years' tenure of such extension the Corporation may purchase pursuant to Section 43 of the Tramways Act. (4) The construction of the extensions to be according to the plans and specifications approved by the borough surveyor; the company will not, however, be required to pave the tracks of these extensions with granite setts in their entirety; 8in. setts shall be laid next the rail on each side, and the track between the setts shall be made up with tarred macadam. (5) The company will agree to the issue of transfer tickets from a point, say the Wheatsheaf, available for Hainton-street and Freeman-street. The Corporation have agreed to these terms, except that the Corporation require to exercise their right of purchase, under the Act of 1901, by valuation, and not as a going concern, that all the leases must expire in 1921, and that the whole of the track be paved with granite setts.

## LIGHTING AND GENERAL.

**Croydon.**—The electric light is to be installed in the borough hospital.

**Walsall.**—The total units generated in May were 118,313 and the output 114,456.

**Southall-Norwood.**—The Southall electric lighting order has received Royal assent.

**London and Rome.**—Telephonic communication has now been established between the post offices of London and Rome.

**Leigh.**—The Corporation have this year experienced a loss on their electricity works of £190, as against a profit of £336 last year.

**Hull.**—An enquiry was held yesterday into the application of the Corporation for a loan for further extensions at the electricity works.

**Warrington.**—An enquiry has been held into the application of the Town Council for sanction to borrow £4,150 for purposes of electric lighting.

**Kirkintilloch.**—An estimate has been prepared for carrying out an electric lighting scheme, and will come before a Town Council committee shortly.

**Bermondsey.**—The Council have decided to oppose the Administrative County of London and District Electric Power Company's Bill now before Parliament.

**Welshpool.**—The Council will consider next week the question of combining an electric generating station with the scheme for disposing of the refuse of the town.

**Goole.**—The Town Council have decided to put down an electric light and power station, and have appointed Mr. Walter Emmott, M.I.C.E., of Halifax, as their consulting engineer for the scheme.

**Calcutta Electric Supply Co.**—The number of units delivered to consumers during the four weeks ending May 26 were 369,487, compared with 304,350 in the corresponding four weeks of the preceding year.

**Bo'ness.**—There was a stormy meeting last night over a question of placing six arc lamps on the cross roads. Ex-Bailie Grant resigned the convenership of the Lighting Committee, which was, however, not accepted.

**Agency.**—The Union Cable Company, Limited, 23, College-hill, E.C., inform us that Messrs. James T. Donald and Co., Limited, 35, McAlpine-street, Glasgow, are now their sole representatives for Scotland for electric cables and wires.

**Sunderland.**—The Rural District Council have consented to an application of the County of Durham Electrical Power Distribution Company, Limited, to the Board of Trade for leave to carry overhead distributing mains under their order of 1904.

**Bath.**—The Baths Committee have instructed Mr. A. J. Taylor, architect, to obtain tenders for various works at the baths, estimated at £1,000, and including the provision of electric radiators to supersede gas stoves and other present means of heating.

Digitized by Google

**Explosion.**—A small explosion occurred just before eight o'clock on Saturday morning in one of the distributing boxes belonging to the Metropolitan Electric Supply Company. The brigade extinguished the fire with sand.

**Ashton.**—Tenders are to be obtained for a new boiler and the disposal of the old ones and for a large additional generator. Plans are to be prepared for the extensions to the engine-room and alterations in the boiler-house. A loan of £3,157 is required.

**City and Guilds of London Institute.**—Particulars of the courses of instruction at the Institute's Central Technical College, Exhibition-road, S.W., and at the City and Guilds Technical College, Finsbury (Leonard-street, E.C.), will be found in another column.

**Telegraph Messengers.**—Major-General L. G. Oliphant, commanding the Home District, on Friday inspected in Hyde Park about 1,000 London postal telegraph messengers. The lads were accompanied by their bands, and a march past, physical drill to music, and various exercises were gone through.

**Richmond.**—The Richmond Electric Lighting Company will oppose the Administrative County of London Electric Supply Bill. It appears that the Council are bound to petition against the Bill under the agreement with the company, and the matter has been left to the General Purposes Committee.

**Alloa.**—The British Electric Plant Company have offered to accept £10,000 to terminate the agreement with the Town Council. The Town Council, however, have decided to cut off the street arc lamps, believing that £168 saving might be effected by the substitution of incandescent lamps in the place of arc lamps.

**Wilmslow.**—Electricity is to be introduced for street-lighting purposes by the Alderley Edge and Wilmslow Electric Supply Company. About 15 miles of cables are being put down, and about 210 lamps will be erected, many of which will be of 70 c.p., but lamps of 140 c.p. will be provided for certain points.

**Worthing.**—The Corporation have decided to apply for sanction to borrow the sum of £3,300 for electric lighting purposes. Mr. Porter, the Corporation electrical engineer, estimates that the total outlay during the period 1905 09 required to cope with the normal increase of business in the present area of supply is £10,847.

**Lowestoft.**—During May 10 new consumers were connected, representing 807 8-c.p. lamps. There are now 619 consumers, representing 31,573 8 c.p. lamps. As a result of last year's work the district rate profited by £1,500—or 3d. in the £ towards the reduction of the rate—a balance of £1,390 being kept as working capital.

**City of London Electric Lighting Co.**—The directors have declared the following dividends on account of the distribution for the year 1905: 6s. per share on the preference shares, 5s. per share on the ordinary shares. The dividends will be subject to the deduction of income tax, and will be payable on and after July 15 next.

**King's Lynn.**—The annual accounts of the electricity department for the year ending March 31 show a profit of £386 as compared with a profit of £486 for the previous year. The income amounted to £5,909. 18s. 1d. and the expenditure to £5,543, the latter item including £2,948 paid for interest and the reduction of capital account.

**City of Wellington Electric Light and Power Co.**—The directors have declared a dividend on the ordinary shares of the company at the rate of 10 per cent. per annum for the half year ended Dec. 31, 1904, making 7½ per cent. for the year, and after placing £5 000 to a reserve and contingency account, £2,044 remains to be carried forward.

**Electrical Standardising, Testing, and Training Institution.**—Prof. C. A. Carus-Wilson, M.A., M.I.E.E., commenced a special course of lectures to the senior students of the above institution on June 15 upon "Direct-Current Motor Construction." The lectures will be delivered on every subsequent Monday and Thursday for the remainder of the term.

**Newfoundland.**—It is proposed to tax the Anglo-American Telegraph Company for five cables at 4,000dol. each, regarding the other four cables as extensions of the former. Another cable company is seeking landing privileges on the island, and the Canadian Marconi Company have established three wireless stations on the island, which are to be taxed at 4,000dol. each.

**Northampton Institute Engineering Courses.**—At the entrance examination for the day courses in engineering to be held next September, the governing body of the institute has decided to offer three scholarships for open competition. These scholarships will give exemption from fees, amounting to £52, during the whole of the four years' course in mechanical or electrical engineering.

**Brentford.**—The Board of Trade, after considering the representations made on behalf of the District Council and the two companies, who had applied for provisional orders, have decided to dispense with the consent of the District Council in regard to the application of the Brentford Electric Supply Company, and to grant the order. The application by the Metropolitan Electric Supply Company was refused.

**Stock Exchange.**—The Stock Exchange Committee have ordered the undermentioned securities to be quoted in the official list: County of London Electric Supply Company's £250,000 4½ per cent second debenture stock, in lieu of the provisional certificates now quoted, together with a further issue of £150,000 4½ per cent. second debenture stock; Wellington (City of) Electric Light and Power Company's £75 000 5 per cent. registered first debentures of £50 each, Nos. 1 to 1,500.

**Leeds.**—The returns of the Electricity Committee for May show the largest increase hitherto recorded in the lamps and motors connected to the mains. Expressing the additional connections in the equivalent of 35-watt lamps, the greatest figure in any previous month was 10,561 in October, 1903. The corresponding figure for last month was 10,955. The increase is mainly accounted for by orders for the supply of power, the motors added during the month having a total capacity of 252 h.p.

**Kirkcaldy.**—The annual report on the electric lighting and tramway schemes show that on the electric lighting there is a net deficiency of £403 after paying all interest on the sinking fund charges, and to this must be added a debit balance last year of £42. The net revenue from private lighting increased by £388 last year. It is proposed to hold an electric household apparatus exhibition to advertise the undertaking.

**Coventry.**—The Electric Light Committee have considered the question of making arrangements for the maintenance of electric lamps on consumers' premises by the Corporation, with a view to minimising complaints as to inferior light caused by worn-out lamps. It is now proposed to undertake the maintenance and renewal of these lamps at the following rate of charges: 25 lamps and under, 2s. 6d. per quarter; over 25 and under 50, 4s. 6d.; over 50 and under 75, 6s. 6d.; over 75 and under 100, 8s. 6d.; over 100, 8s. per 100.

**Lincoln.**—The accounts of the electricity works and tramways undertaking for last year show a net profit of £1,161, and a balance at credit of £254. The total capital expenditure was £51,333 and the debt on the undertaking was £44,904. The tramways undertaking showed a gross profit for the nine months of £967, and a net profit of £241. The traffic receipts were £2,759, as compared with £2 869 for the corresponding period of the previous year. The total capital expenditure on the undertaking had been £16,115 up to March 31.

**Handsworth.**—The public and private electric lighting scheme is rapidly approaching completion. The cables are laid in all the scheduled area, the columns are nearly all erected, and the lamps themselves will shortly be fixed. The chimney shaft at the generating station in Piers-road is not quite completed, but the engines and the switchboard are erected and being connected up. The charge for current will be 6d. per unit for the first 100 units per quarter, and 4d. after. Churches and chapels will be supplied at a uniform rate of 4d. per unit.

**Islington.**—The Borough Council have decided upon the extension of generating plant at the electric lighting station, as follows: one 1,500-kw. turbo-alternator, including exciter, condenser, pumps, etc., £9,000; foundations for above, £250; steam-pipes, hot-feed apparatus, etc., £1,500; one cooling tower capable of dealing with water for above, £3,750; motors, fans, piping, etc., £500; contingencies, £500—total, £15,500. It has also been decided to apply for power to borrow £632 for the erection of additional buildings at the rear of the disinfection station in Seven Sisters-road.

**Southport.**—The year's working of the Corporation's electricity department shows a net profit of £3,355. The total revenue amounted to £22,583 and the gross profit to £14,771. Interest and sinking fund absorbed £11,415. The amount already paid in reduction of debt amounts to £32,878. The surplus has been dealt with as follows: in aid of rates, £2 500; rates' expense account, £284; and balance and profit and loss account, £570. For the next financial year £2,500 has been promised in aid of the rates. A sub-committee has been appointed with power to approve a plan and accept a tender for galvanised store sheds at the Eastbank-street yard.

**New Issues.**—The Oriental Telephone and Electric Company, Limited, are issuing £100,000 of 4 per cent. redeemable debenture stock at the price of £92 per cent. for the purposes of providing the cost of converting the company's lines to metallic circuits, of extending and developing its telephone and electrical business, and of assisting the subsidiary companies so far as they may require financial assistance. The Electric Supply Company of Victoria, Limited, are issuing £160,000 of 5 per cent. first mortgage debenture stock for further expenditure on the electric lighting, power, and tramway concessions for the cities of Ballarat and Bendigo in the State of Victoria.

**Louth.**—The Town Council are raising £17 000 in respect of the installation of electric light within the borough. Messrs. Hancock and Dykes, the consulting engineers, propose in the first instance to put down two vertical oil-engines at a cost of £1,950 each, coupled to a 75-kw. dynamo, and a battery of accumulators. In those streets in which electric light mains are laid it is proposed to convert the present gas street lamps to electric lamps, fitted with arc and incandescent lamps for after-midnight service. The estimated cost of the works shows the necessary immediate outlay to amount to £12,230, while prospective expenses to be incurred during the first two years bring the estimated cost up to £16,980.

**Iceland Cable.**—Captain J. Boyle, the British Consul at Copenhagen, in his report to the Foreign Office for 1904, states that during September negotiations were concluded between the Danish Government and the Great Northern Telegraph Company for the establishment of telegraphic cable communication with Iceland. Under the terms of a 20 years' concession the company undertake to lay down and work a telegraph cable between the Shetland and Faröe Islands and Iceland. The cable end will be landed at Seydisfjord or Reydarfjord on the east coast of Iceland, and the company is to receive an annual subsidy of £3,000 from the Danish and £1,950 from the Icelandic Exchequer. It is stipulated that the cable shall be opened and ready for work by Oct. 1, 1906, at the latest.

**Electric and General Investment Co.**—The directors recommend the payment of the following dividends for the year ended May 31: On the ordinary shares, a dividend of 4s. per share, of which 1s. per share was paid on account in January last, leaving 3s. per share to be distributed. The trustees for the ordinary shares reserve fund propose to distribute out of the dividends received 1s. per share, making a total present distribution of 4s. per share, or £0 per cent., or a total distribution of 5s. per share, or 25 per cent., for the year. On the founders' shares, a dividend for the year of £20 per share is proposed, and the trustees for the founders' shares reserve fund propose to distribute out of the dividends received £10 per share, making a total present distribution for the year of £30 per share.

Digitized by Google

**Cardiff.**—The borough electrical engineer and manager (Mr. A. Ellis) in his last report states that there are now 1,149 consumers connected with the mains, with a total equivalent of 135 384 8-c.p. lamps. The total number of lamps at the corresponding period last year was 111,335, an increase of 21 per cent. in the total connections. The estimated revenue from street lighting was £630, that from private supply was £1,814, as against £1,653 for the corresponding month last year. A number of leading tradesmen having asked for a 10 per cent. cash discount in the price of current, Mr. Ellis, reporting upon this petition, said the department's income for the last year was £33,000. If they allowed a 10 per cent. discount they would lose £3,300 per annum, and while granting their consumers 10 per cent. they would only get 4 per cent. from the bank.

**Gillingham.**—The Council's decision to supply the Kent Electric Power Company, in consequence of the Chatham fire, with electrical energy for their customers for a minimum period of six months at 2½d. per Board of Trade unit, is subject to an agreement embodying, amongst others, clauses to the effect (1) that in the event of a breakdown occurring which makes it impossible to supply both the Kent Electric Power Company and the Gillingham area, it must be understood that the Council have power to disconnect the supply to the Kent Electric Power Company until the breakdown is rectified; (2) the Kent Electric Power Company to lay down the connecting main across the Great Lines at their own expense and risk, and provide a step-up transformer at the Council's generating station. A new boiler will have to purchased and fixed at the generating station capable of evaporating 5,000lb. of water per hour at an estimated cost of £1,000.

**Ipswich.**—The Electric Light and Tramways Committee's report for the year ended March 31, 1905, shows that the number of consumers was on March 31, 1904, 98, and at the end of the year 209, and there was an increase of 19,977 in the equivalent number of 8-c.p. lamps connected to the mains during the year. The units generated during the year amounted to 1,189,872, the units sold to 1,066,285, of which 797,370 were for traction and the remainder for lighting and power. There was 12·2 per cent. of units generated for lighting and power unaccounted for, and 76,039 units used on the works. The total length of lighting mains now laid is 22,806 yards, or 12·96 miles. The receipts were £8 938 which leaves a balance of £2 605 over the working expenses. Interest on loans amounted to £2,522, and repayment of loan (net) £1 761, leaving a total deficiency (including £1,350 from the rate in aid and £742 deficiency at March 31, 1904) of £2,420, the net deficiency for the year being £387.

**Stirling.**—Mr. A. C. Hanson, the burgh electrical engineer, in his annual report gives the number of units generated during the year ending May 15 as 260,755, as compared with 228,790 for the previous year. During the year 2,514 equivalent 8-c.p. lamps were connected to the mains, representing an increase in the possible demand of 81 kw. The total maximum demand was 207 kw. on Dec. 22, as compared with a maximum demand of 176 kw. the previous year. This demand represents 6,300 equivalent 8 c.p. lamps alight at one time. The average price obtained from the whole private supply was 4·131. per unit, as compared with 4·421. last year. The capital expense for interest for the year was £2,128. The revenue amounted to £4,137, compared with an estimated revenue of £4,130 and last year's revenue of £3,642. The running costs amounted to £1,740, as compared with an estimate of £1,775. The expenses of management, etc., amounted to £436. Owing to a sum of £177 having to be taken from the capital to the revenue account on the instructions of the Secretary for Scotland, being part of the cost of securing the provisional order, a sum of £305 will be required from the rates, as compared with the estimate of £110.

**Dundee.**—The Gas and Finance Committees have resolved to recommend that the price of current to ordinary consumers, otherwise than by agreement and otherwise than for motive power, per quarter should be as follows: for any amount up to 20 units per quarter, 6s. 8d.; and for each unit above 20 units, 4d.; and that all consumers who consumed above 10,000 units per annum be supplied at 3d per unit in excess of that figure, in all cases a discount of 5 per cent. being allowed if payment be made within 28 days. Public electric lamps are to be charged at the rate of £15 each per annum for those burning the whole night, and £7. 10s. for those burning a part of the night. The charge for motive power is to be on the maximum demand system, at a variable rate from a maximum of 2½d. per unit downward; and for heating, cooking, and radiators at 2d. per unit (each consumer to use or pay for current up to a minimum of 6s. 8d. per quarter) if taken through a separate meter, but if not taken through separate meter at the ordinary rate of 4d. per unit, subject to discount. The rate for the supply and distribution of current for tramways was fixed at 1½d. per unit. The commissioners will supply new consumers at the standard pressure of 200 volts, and by special agreement 400 volts at consumer's terminals.

**Darlington.**—The Northern Counties Electric Supply Company, Limited, have erected a new generation and refuse destructor works at New Shildon, near Darlington, and they were formally opened this week, although the light has been supplied to the district for six weeks. At the ceremony, the members of the local District Council, the Spennymoor Urban District Council, and a number of other interested people were conducted over the works while in operation by Messrs. Fairweather and Vesey-Brown, representing the company. The destructor, which will be a great boon to this thickly-populated colliery district, and will save fully £300 per annum, has four cells, and is of the Heenan patent type, working in connection with two Babcock and Wilcox water-tube boilers, with a heating surface of about 3,900 square feet. The intercommunicating grate system of furnaces is used, and they have a guaranteed combined capacity of from 40 to 45 tons of refuse per 24 hours. At the official test the furnaces burned at the rate of 64 tons, with an evaporation of over 1¾lb. of steam produced at 200lb. per square inch pressure, and an average temperature of 1,700 deg. F. was maintained throughout. At present three cells are sufficient to deal with the daily deliveries, amounting to about 30 tons, largely made up of crude sewage, coal, and shale. The whole supply of electric light, which is being largely adopted in the district, is developed from the cremation of the refuse. The Electricity Committee of the Corporation have decided to extend their cable to Albert-hill, an important industrial district of the borough, on account of the proprietors of the Darlington Wireworks having expressed their desire to manufacture with electric power instead of steam.

**Manchester.**—The annual statement for the year ended March 31 shows an income for the year of £302,200, including £182,560 for lighting and power and £117,590 for traction. The working expenditure was £174,320, and after interest on the mortgage debt and the sinking fund had been provided for there remained a net surplus of £4 544. The reserve fund at the beginning of the financial year stood at £32 561, but now only amounts to £20,387, the decrease being mainly due to expenditure in respect of vibration and explosion lawsuits. The capital outlay shows a total at March 31, 1905, of £2,199 689. Application has been made to the Local Government Board for further borrowing powers to the extent of £60,000 for additional machinery to be erected at several of the distributing substations. Provision has been made in the 1906 estimates for a reduction in the charges for current supplied for lighting purposes, and the Council will be asked to sanction a reduction to short-hour consumers from 5½d. to 4½d. per unit, to take effect from Sept. 29 next. An agreement has been entered into with the Gorton Urban District Council taking over their provisional order for the supply of electricity in their district. The total output of electricity from the works during the past 12 months amounted to 47,170,721 units, as compared with 38 610,922 units of the previous year, an increase of 22·17 per cent. The quantity measured and accounted for during the same time was 36,979,552 units, showing a difference of 10,191,169 units, or 21·60 per cent., being the quantity used in distribution or otherwise not accounted for. The total mileage of mains laid at March 31, 1905, equals 892 miles 165 yards. The Electricity Committee are prepared, for the purpose of illumination on the night of Thursday, July 13, to supply current from existing services at a charge of ½d. per 8 c.p. lamp per night from dusk to midnight.

**Administrative County of London and District Electric Power Bill.**—This Bill will come up for second reading in the House of Commons about Wednesday next, having been approved by Lord Camperdown's Committee. Notices of intended opposition have been given on behalf of the Corporation of London, the London County Council, the Corporations of East and West Ham, Southwark, Battersea, Lambeth, Wandsworth, Bermondsey, Islington, Stepney, Lewisham, Camberwell, Deptford, Poplar, Fulham, St. Pancras, Shoreditch, Woolwich, Croydon, Richmond, Kingston-on-Thames, Bromley, and Gravesend, the Urban District Councils of Beckenham, Bexley, Dartford, Barnes, and Wimbledon, the Rural District Councils of Bromley and Croydon, the Chelsea Electricity Supply and St. James's and Pall Mall Electric Light Companies, Richmond Electric Light and Power Company, Central Electric Supply Company, County of London Electric Supply Company, Charing Cross, West End, and City Electricity Supply Company, South Metropolitan Electric Tramways and Lighting Company, Empire Electric Light and Power Company, Metropolitan Electric Supply Company, Metropolitan Water Board, the Commissioners of Sewers, the Gaslight and Coke, South Metropolitan, Mitcham and Wimbledon, and Wandsworth and Putney Gas Companies, London United Tramways Company, Great Northern, Piccadilly and Brompton, Baker-street and Waterloo, and Charing Cross, Euston, and Hampstead Railway Companies, and Messrs. Brunner, Mond, and Co. The Bill of the North Metropolitan Electric Power Supply Company will be opposed in the Commons by the London County Council, the Charing Cross, West End, and City Electricity Supply Company, and the Urban District Councils of Wood Green and Walthamstow. Mr. J. Falconer has written to the London County Council on behalf of the promoters of the Administrative County of London and District Power Bill in regard to a letter sent by the Council to members of Parliament requesting them to oppose that Bill and that of the Metropolitan Electric Supply (Various Powers) Bill, pointing out that in their letter the only prices mentioned were 1d., 8d., and 7d. per unit, leaving it to be inferred that these prices, which only applied in isolated and special cases, represented the prices generally charged, whereas the returns furnished by the companies and local authorities themselves showed that in the case of both the average price paid by consumers for power was over 2d. per unit, or more than double the figures stated. The figure of 114,000,000 units per annum was mentioned as representing the business of the existing undertakings. This left it to be inferred that the whole of this would be affected by the Bill, whereas it was admitted that the new company would not compete for their existing business to any practical extent, except as regarded supply to manufacturers in the industrial area, or less than 6 per cent. of that figure. Similarly the statement suggested that the whole capital of the existing undertakings in London—namely, £17 983,000—would be affected by the Bill, whereas, as a matter of fact, but a small percentage of that amount has been expended in connection with the supply of power. He also complains that in the said letter no reference was made to the interest of the consumer in a supply of electricity at an average price of ¾d. per unit, and points to the advantages which would accrue to manufacturers being supplied at the low rate.

**Plymouth.**—The accounts of the fifth year's working of the Corporation's electricity undertaking shows that during the year ending March 31 114 additional consumers had been added, with an equivalent of 9,246 lamps. The total number of consumers is 667, the total connections of lamps, etc., on private consumers' premises being equal to 50,770 lamps of 8 c.p., against 553 consumers and 41,524 lamps in 1904. The use of electric motors was increasing, there being about 50 in use by private consumers. The total units sold during the year

Digitized by Google

was 1,699,460, being 190,367 units more than during the preceding year. The cost of production was less than during any preceding year. The works costs this year were 1·05d. per unit sold, against 1·13d. in 1903-4, and the total costs 1·41, against 1·49. The expenditure on coal had been reduced from ·71d. in 1903-4 to ·64d. per unit sold in the past year, a gain of 11 per cent. The machinery, plant, and buildings had been fully maintained out of revenue at a cost of £1,350. The sum of £3,130 had been paid off by way of rates since the commencement of the undertaking. Notwithstanding the reduction made in the charges to private consumers, the gross profits showed a substantial increase over the previous year, the figures being £10,325 for 1904-5 and £9,175 for 1903-4. The balance in the reserve fund now stands at £4,869.

**South Shields.**—An enquiry has been held into an application of the Corporation for sanction to borrow £15,625 for extensions at the electricity works at Holborn to meet the requirements of the electric tramway service. The town clerk, Mr. J. Moore Hayton, said the undertaking which was inaugurated in 1896, had now reached considerable dimensions, and had had a successful career. The capacity of the plant installed was 1,600 kw., and the maximum demand at any time last year was 953 kw., so that there was a large margin of plant available for the supply of current. The plant, however, being on the alternating system, was not altogether suitable for tramway purposes, or for the supply of power to works, therefore it was proposed to instal plant for traction and power purposes supplying a continuous current of 500 volts. This would take the form of two units of 550 kw. capacity each, with a reciprocating engine and dynamo. A boiler, additional pumps, switchboard, and some other items of machinery would be necessary for the purpose of completing the installation. The estimated cost of the work in the electrical engineer's department was £14,425, and there would be, in addition, a little architectural work to cost, it was estimated, £1,200, mainly for the foundations, the engine, dynamo, the construction of the switchboard platform, etc. The capital expenditure on the electricity undertaking had been £151,838; the loan outstanding amounted to £133,444, less sinking funds in hand £11,056, leaving a net indebtedness to the amount of £122,388. The reserve fund accumulated was £4,500, and the net profit last year was £2,055. Mr. James Albert Cawthra, borough electrical engineer, detailed the work which had been carried on, the progress which had been made since the commencement of the electricity undertaking, and the additions it was proposed to make.

**South Africa.**—Electric motors have now been installed for the working of the batteries of the Cason and Angelo mines, and the results achieved will be looked for with considerable interest in this country. Germane to the same subject is the projected installation of an electric hoist on the Village Main Reef mine, which, we understand, is the first to be adopted for deep-level mining. The problem of length of haul will be met by placing the winder at a vertical depth of 1,100ft., where it will haul on a 1,700ft. incline. The generating plant will be of 900 h.p., and the hoist 500 h.p. The A.E.G. Electrical Company of South Africa, Limited, is supplying the electrical portion of this equipment, Messrs. Fraser and Chalmers, Limited, the mechanical parts of the hoist, and Messrs. W. H. Allen, Son, and Co., Limited, the steam plant. The several electrical undertakings in course of construction in the Cape Colony and Natal continue to make steady progress, and add considerably to the budget of oversea orders being duly given out, while some new schemes have also been launched which will eventually afford their measure of business. At Port Elizabeth the tender of Messrs. Wills and Davey, for the erection of the generating station, has been accepted, and will involve the placing of orders for ironwork and builders' material. The Corporation of Cape Town have taken in hand the work of replacing many of the overhead lines by underground feeder cables, and with a large increase in the demand for light in the district near the Opera House, and for the service of the new City Hall, have been under the necessity of indenting for further electrical material, a portion of which has been placed with Messrs. Ingram and Kemp, Limited. No time has been lost by the King William's Town Town Council in enlarging its newly-acquired electric installation to meet the increased calls for light, and among the new plant already contracted for is a 100-kw. alternator, placed with the Electrical Construction Company, Limited, an "Economic" boiler, supplied by Messrs. Davey, Paxman, and Co., Limited, and four 20-kw. transformers of Messrs. Ferranti and Co.'s make. Orders for 50 electric meters have also been given out. Among the new electric schemes for which material will shortly be called for is that of Beaconsfield, in Cape Colony; Greytown, in Natal; and Bloemfontein, the concession for which is in the hands of Messrs. Hubert Davies and Spain, Johannesburg.—*South African World.*

**Bermondsey.**—At the Borough Council on Tuesday a long debate arose over a report from the Electric Lighting Committee respecting breakdowns which occurred on June 8 and June 10 in connection with the municipal electric light. Mr. Doran, the electrical engineer, said the breakdowns were due to the dampness of the places where the service had been laid in the past. The cable could have been laid in another manner. The drop in the whole system only lasted whilst another machine was being got in. At the same meeting the Electric Lighting Committee reported that since May 5 the number of equivalent 8-c.p. lamps applied for for private lighting was 130, making a total of 36,498 8-c.p. lamps applied for to date, or, including public lighting, a grand total of 39,484. The number of customers up to date was 216, and 6,840 8-c.p. lamps had been applied for in excess of the capacity of the present plant. The committee also reported that it had considered a statement, marked private and confidential, outlining the heads of the terms upon which the promoters of the Administrative County of London and District Power Bill were prepared to negotiate with the Borough Council with a view to the withdrawal by the Council of its opposition, and the supply by the company to the Council of electrical energy. Having very carefully considered the matter, the Council said they were not prepared to recommend the Council to withdraw its opposition to the Bill. The Council endorsed the opinion of the committee. The committee also reported having received from the Board of Trade an intimation with reference to the London Electric Supply Corporation's application for an additional system for the supply of energy for the purposes of its 1889, 1900 (Metropolitan), and 1897 (Westminster) orders, the Board of Trade had after full consideration given its approval. The Electric Light Committee reminded the Council that in March last it had written asking the Board of Trade before approving of the additional system to afford it an opportunity of appearing before them on the matter, as the additional system would enable the company to come into more direct competition with the Council's undertaking, and also calling the Board's attention to the fact that there was already another company in the borough besides the one mentioned. The chairman of the committee together with the town clerk and electrical engineer waited on the Board of Trade regarding the matter. The Council said they had directed that a reply be sent to the Board of Trade protesting against the granting of the approval, especially as another company is now seeking powers to come into the borough. This action the Council approved.

**Norwich.**—The report of the Electricity Committee for the year ended March 31 last shows a gross profit of £16,574, as against £15,147 for the previous year, and subject to the charge for interest on the loan debt and contributions to sinking fund for the year, there is a balance of £5,433, as against £4,432 for last year, which, with the balance brought forward for the three months to March 31, 1903, makes an accumulated total of £10,018 to be dealt with. The report states: "The committee in considering how this sum should be appropriated have been met first of all with the necessity for writing off the balance of outlay on certain small engines which were taken over when the undertaking was purchased, but which, owing to the development of the business, require to be replaced by engines of a larger type, not only on grounds of efficiency, but also of economy. The difference between the price at which these engines stood in the accounts of the company after allowing for depreciation already provided and their selling price is £3,765, a sum which must be met out of the above balance of £10,018. The committee have also very carefully considered the necessity for setting aside a substantial depreciation fund which will serve to provide not only for the obsoletion of machinery, but also for depreciation. They therefore propose carrying £6,000 as a first contribution to this fund, which will leave the sum of £253. 11s. 4d. in the net revenue account to be carried forward to next year. The total amount provided for sinking fund towards the extinguishment of the loan debt is now £6,465. This sum covers the requisite contributions to March 31, 1905, and is calculated on the terms of years allowed under the Norwich Corporation (Electricity, etc.) Act, 1902, for the repayment of the loan debt. The following is a comparison of the results of the last two years' working: Units sold, 1903-4, 1,819,708; 1904-5, 2,087,942; increase, 278,234. Receipts, 1903-4, £28,733; 1904-5, £30,259; increase, £1,526. Working expenses, 1903-4, £13,585; 1904-5, £13,684; increase, £99. Proportion of expenses to receipts, 1903-4, 47 per cent.; 1904-5, 45 per cent. Remembering that your committee with the sanction of the Council in November last decided to reduce the charge for electric current from 5d. to 4½d. per unit to take effect as and from Jan. 1 last, the increase compares well with previous years, for if there had been no reduction the increase in the receipts would have been about £2,300. This, it is satisfactory to note, has been obtained with additional expenditure of only £99. The economy that has been effected has been principally in the coal consumption, but it is also due partly to the change of pressure completed during the past year, which has very much reduced the loss in the mains, and also to the fact that we are able to make much more use of our large engines. The other expenses have not increased in the same proportion as the output, and are not likely to do so in the future. It is interesting to note that although the increase in output has been maintained the capital expenditure has not been so high as in previous years. At the end of 1902 the total amount expended by the Corporation on the undertaking including the purchase was £240,558, and during that year 1,481,000 units were sold; that is to say, £162 had been spent for each 1,000 units sold. Since the end of 1902 £21,296 more has been spent, but the output per annum has been increased from 1,481,000 to 2,093,000 units, or by 617,000 units. The expenditure for this increase is, therefore, only £35 per 1,000 units, and this will probably be about the cost for future development. The progress in new connections has been practically the same as previously, 273 having been added as compared with 279 the year before. The total number of consumers now is 3,283, with lamps equivalent to 102,000 8 c.p., and 250 motors, with an aggregate of 1,105 h.p. A special feature of the year has been the introduction of a system for the maintenance of lamps on consumers' premises. It was found that a great many people were not getting satisfactory results simply because the lamps were not renewed as often as they should be, and your committee, realising that their obligations did not end with the supply of current, but that every endeavour should be made to give the best possible results that could be obtained, decided to offer to keep any consumer's lamps in good order for such an amount as was estimated to be sufficient to cover the cost. This has met with great success, and during the year some 300 consumers have accepted the offer. When the benefits are more fully realised, there is little doubt but that the department will be asked to attend to the great majority of the consumers' lamps. As a recent instance of the growing appreciation of this, it may be mentioned that one of the most important local companies, after fully considering the whole question, have decided to take current from the Corporation for working some new machinery they are putting down to the extent of 120 h.p., rather than put down their own plant. Other large firms are considering the working of their machinery by electric motors, and your committee hope to be

Digitized by Google

able to report some substantial additions in this direction during the present year. In conclusion, they wish to impress upon the citizens that the prospect of further reductions and of future benefits depend on the way in which the business increases. They consider that there are great possibilities of further development with reduced cost of production, but these results cannot be obtained without a considerable increase in the output." The report came before the Council this week, and consideration was deferred.

## PROVISIONAL PATENTS, 1905.

JUNE 10.

**12150. Improvements in apparatus for compressing or setting the bonds of electric railways and tramways, and for other analogous purposes.** John Shaw, 18, St. Ann-street, Manchester.

**12170. Improvements in electrical cables.** Henry Edmunds and Philip Dawson, 47, Lincoln's-inn-fields, London.

**12171. Improvements in and connected with electrical cables or conductors.** Henry Edmunds and Philip Dawson, 47, Lincoln's-inn-fields, London.

**12182. Improvements in arc lamps.** Richard Philip Myers, 322, High Holborn, London.

**12193. Improvements in and relating to means for starting and controlling alternating-current motors.** William Edward Evans, 27, Chancery-lane, London. (The Allgemeine Elektricitäts-Ges., Germany.)

**12202. Improvements in electric bells.** Shanker Abaji Bhisey, 38, Chancery-lane, London.

JUNE 13.

**12205. Means for joining up two or more electric circuit wires or like conductors.** Verity's, Limited, and William George Pipkin, 11, Burlington chambers, New-street, Birmingham. (Complete specification.)

**12212. Improvements in trolley fittings for use in connection with overhead electric traction systems.** Frank Woodhead, 24, Temple-row, Birmingham.

**12218. A pricker or bit for perforating electric casings ready for insertion of screws.** John Dugdill, 305, Oldham-road, Failsworth, Manchester

**12221. Improvements in or relating to electrolytic apparatus.** George Grant Hepburn, 4, St. Ann's square, Manchester.

**12241. A swivelling mercury contact for use on electric tramcars and the like.** William Glennon, 22, Hulme-street, Elton, Bury, Lancs.

**12249. An improved process for depositing metals from solutions with a specially-constructed brush by electricity without the aid of baths.** George William Hartopp Simpson and Percy May, St. Amant, Park Fields, Putney, London.

**12253. Improved electric accumulator plates for the storage of electricity.** Frederick Thomas Kelley, 8, Elders-street, Scarborough, Yorks.

**12263. Electrolytic ship-bottom cleaner.** George Washington Frazier, 7, Staple-inn, Holborn, London. (Complete specification.)

**12284. Improvements in and relating to electric tremblers.** Jean Baptiste Minoggia and Léon Emile Mére, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, June 19, 1904, being date of application in France.) (Complete specification.)

**12291. Process for the electrolytic production of lustrous metallic coatings upon metals.** Alexander Classen, Birkbeck Bank-chambers, Southampton-buildings, Chancery-lane, London. (Complete specification.)

**12294. Improved trolley pole for conducting electric current to vehicles.** John Lindsay and Robert Lindsay, 53, Chancery-lane, London.

**12296. Improvements in devices for magnetically increasing the adhesion between truck wheels and the rails upon which they roll.** Robert Charles Lowry, 1, Queen Victoria-street, London. (Complete specification.)

**12307. Improvements in time-limit devices for electric switches or circuit breakers.** The British Thomson-Houston Company, Limited, Edmund Basil Wedmore, and James Whitcher, 83, Cannon-street, London.

**12315. Improvements in galvanic batteries.** Benjamin Jacob Blameuser, Elsie Corine Blameuser, Nicolas Kribs, and William Joseph Burle, 40, Chancery-lane, London. (Complete specification.)

JUNE 14.

**12341. Improvements in sanitary attachments for telephones.** Isaac Michael Slocum, 65, Chancery-lane, London. (Date applied for under Patents Act, 1901, June 22, 1904, being date of application in United States). (Complete specification.)

**12367. Improvements in electrical exosmosers.** Carl Adolph Sahlstrom, 6, Lord-street, Liverpool. (Date applied for under Patents Act, 1901, June 21, 1904, being date of application in United States.) (Complete specification.)

**12382. Improvements in automatic selecting apparatus for use in telegraphy and telephony.** Paul Arnheim, 322, High Holborn, London.

**12386. Improvements in supports for electric overhead conductors.** Edgar Douglas Machray, 18, Southampton-buildings, Chancery-lane, London. (Herbert John Machray, Constantinople.)

**12388. Improvements in alternating-current generators.** Giovanni Battista Marzi, 7, Southampton-buildings, Chancery-lane, London. (Date applied for under Patents Act, 1901, June 15, 1904, being date of application in Italy.) (Complete specification.)

JUNE 15.

**12399. Magneto-electric dumb bell.** James Moores, St. Lesmo, Hastings-avenue, Chorlton-cum-Hardy, Manchester.

**12406. Improvements in and connected with telephone mouthpieces.** Rudolf Knoll, 4, Corporation-street, Manchester. (Complete specification.)

**12418. Improvements in or relating to the distribution of energy to commutator electric motors from a three-phase alternating-current source.** Benjamin Garver Lamme, Westinghouse Patent Bureau, Westinghouse Building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, June 30, 1904, being date of application in United States.) (Complete specification.)

**12420. Combined electric railway cab signal and automatic block system.** Joseph Whitman Buell, 601, McGill-building, 903 to 914 G. Sts, N.W., Washington, D.C., United States. (Complete specification.)

**12424. Improvements in electric telegraphy.** Isidor Kitsee, 18, Fulham-place, Paddington, London. (Complete specification.)

**12431. Improvements in or relating to electrical instruments.** Michael Birt Field, 111, Hatton-garden, London.

**12432. Improvements in or relating to automatic cut-offs or interrupters for electric current.** Domingo Carvera Cañizares, 111, Hatton-garden, London. (Date applied for under Patents Act, 1901, June 30, 1904, being date of application in Spain.) (Complete specification.)

**12454. Improvements in the electro-deposition of copper and other metals.** Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

**12455. Improvements in removing metallic cylinders from mandrels on which they are electro-deposited.** Sherard Osborn Cowper-Coles, 4, South-street, Finsbury, London.

JUNE 16.

**12473. An improved junction box for electric cables.** Thomas Bertram Reader, 62, Belmont-road, Beckenham.

**12485. Improvements in magnetic compasses and the like.** Walter Taylor St. Aubin, 1, Langham-chambers, All Souls'-place, London.

**12496. Helix spark plug for the electric ignition of motors.** Emile Evrard, Birkbeck Bank-chambers, Holborn, London. (Date applied for under Patents Act, 1901, March 6, 1905, being date of application in Belgium.) (Complete specification.)

**12507. Improvements in and relating to prepayment mechanism for electric meters.** The British Thomson-Houston Company, Limited. Wiliam John Lloyd, and Kenneth Francis Kingwell, 83, Cannon-street, London.

**12536. Improvements relating to electric incandescent candle fittings.** Frederick Roberts Pope, 322, High Holborn, London.

**12543. Universal telephone call.** Madeleine Fouques, 40, Chancery-lane, London. (Complete specification.)

JUNE 17.

**12546. Improvements in apparatus for use with Nernst lamps and the like.** Robert William Paul, Newton-avenue Works, New Southgate, London.

**12559. Improvements in the construction of electrical resistances.** George Keith Buller Elphinstone, Century Works, Lewisham, London.

**12586. Improvements in or relating to electric telegraphy** Edmund Raymond-Barker, 111, Hatton-garden, London.

**12590. Improvements in electrical igniters for explosion motors.** Karl Mann, 65, Chancery-lane, London. (Date applied for under Patents Act, 1901, July 11, 1904, being date of application in Germany.) (Complete specification.)

**12591. Improvements in electrical accumulators.** Guglielmo Marconi, 24, Southampton-buildings, Chancery-lane, London.

**12593. Improvements in magnetically-operated switches.** George Henry Hill, 83, Cannon-street, London. Date applied for under Patents Act, 1901, June 18, 1904, being date of application in United States.) (Complete specification.)

**12594. Improvements in electric railway systems.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

**12595. Improvements in and relating to vapour electric apparatus or devices.** Sir Oliver Joseph Lodge, Alexander Muirhead, and Edward Ernest Robinson, 323, High Holborn, London.

**12598. Improvements in and relating to incandescent electric lamps.** Stephen Horvath and the "Utility" Company, Limited, 57, Chancery-lane, London.

Digitized by Google

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published July 6.*

1904.

**12949. Electric apparatus applicable for exercising and therapeutic purposes.** Burks. (Rohlfs, partly.)

**13016. Method of and apparatus for obtaining a constant potential current from a variable-speed dynamo.** Loppé and Compagnie Générale d'Electricité de Creil. (Date applied for under International Convention, Nov. 10, 1903.)

**13017. Method of and apparatus for obtaining a constant potential current from a variable-speed dynamo.** Loppé and Compagnie Générale d'Electricité de Creil. (Date applied for under International Convention, Feb. 20, 1904.)

**13253. Manufacture of filaments for incandescing electric arc lamps.** Crawford.

**13278. Electric transformers, reactances, and the like.** British Thomson-Houston Company, Limited. (General Electric Company.)

**13283. Means for supplying or cutting off current in connection with single or polyphase alternating-current electric motors.** Union Electricitäts Ges. (Date applied for under International Convention, June 30, 1903.)

**13564. Regulation of electric motors.** Johnson-Lundell Electric Traction Company, Limited. (Lang.)

**13585. Electric motors.** Latour. (Date applied for under International Convention, June 19, 1903.)

**14163. Movable overhead frogs or switches for electric railways and tramways.** Merz and Redman.

**15616. Single-phase alternate-current motors.** Crompton and Co., Limited, and Goldschmidt.

**15701. Instruments for determining the drop of potential in electric transmission systems.** Allgemeine Elektricitäts-Ges. (Date applied for under International Convention, July 14, 1903.)

**16408. Electric circuit controllers, especially applicable in connection with the governing of elastic fluid turbines.** British Thomson-Houston Company, Limited, Warwick Machinery Company, Limited, and Samuelson.

**16664. Starting resistances for electric motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**17478. Electric light fittings.** Marsden.

**17562. Printing telegraphs.** White.

**17621. Electric arc lamps.** Veritys, Limited, and Worsley.

**17738. Telephone switchboards.** Parsons.

**17764. Means of regulating electric circuits.** Hill.

**20788. Winding for monophase or polyphase alternating-current electric machines.** Elektricitäts Akt.-Ges. vorm. W. Lahmeyer und Co. (Date applied for under International Convention, Nov. 12, 1903.)

**22100. Certain parts of electrical circuit breakers and automatic switches.** Electric and Ordnance Accessories Company, Limited, and Hall.

**26293. Dynamo-electric generators.** Allgemeine Elektricitäts-Ges. (Date applied for under International Convention, Dec. 3, 1903.)

1905.

**618. Method of controlling the feeding mechanism of electric arc lamps of the open and enclosed types.** Fry.

**1665. Incandescent electric light bulbs.** Bury.

**1912. Electric railway system.** Kinsman.

**2628. Electric ignition arrangements for explosion motors.** Schoeller.

**4168. Telephone transmitters.** Bines.

**7495. Contact devices for electric switches.** Elektricitäts Akt.-Ges. vorm. W. Lahmeyer und Co. (Date applied for under International Convention, May 9, 1904.)

**8613. Apparatus for electrical drying of insulation of electric cables.** Nisbett.

**11360. Manufacture of copper sulphide for thermo-electric couples.** Cie. Thermo-Electrique (Système Hermite) Soc. Anon. (Date applied for under International Convention, April 27, 1905.)

## NOTES.

**Electric Tramway and Railway Exhibition.**—The third international exhibition will be opened at the Agricultural Hall, London, on Monday, July 3, at noon, by the Earl of Derby, and will continue until the 14th.

**International Association of Municipal Electricians.**—The convention of the International Association of Municipal Electricians will be held at Erie, Pa., on Aug. 23, 24, and 25, in lieu of the date previously announced. All indications point to this convention being one of the most successful the association has ever held. The location of the city, by the way, is a happy one, and at the time of the year when the convention will be held the weather conditions are said to be exceptionally good. The list of papers so far announced includes a number of important subjects. The secretary is Mr. Frank P. Foster, Corning, N.Y.

**Belt Creep.**—At the recent meeting at Scranton, Pa., of the American Society of Mechanical Engineers, Mr. W. B. Bird presented a paper, in which he described a number of experiments made on 4in. and 6in. single and double belts. The belts were run without load, and the sum of the tensions was made twice the desired tension, which was taken as 50lb. and 80lb. per inch of width of single and double belt respectively, on the tight side. The corresponding figures for the slack side were 20lb. and 32lb. The average of 10 tests showed a percentage of creep for the various belts as follows: 4in. single, 0·70; 6in. single, 0·67; 4in. double, 0·67; 6in. double, 0·66. The author analyses the test and draws the conclusion that for conditions which exist in good practice the creep should not exceed 1 per cent.

**The Administrative County of London Bill.**—There is likely to be a more or less exciting debate when this measure comes up for discussion in the House of Commons. The Standing Orders Committee have overruled the examiner's decision that, on account of a technicality, the Bill had not complied with standing orders, publication in the *Gazette* of some formal alteration being deemed by him insufficient. Meantime the promoters feel rather sore over the action of the London County Council in addressing various London M.P.'s, asking them to vote for the rejection of the Bill on second reading, instead of its being referred to committee, so that a usually formal proceeding may be transformed into a spirited one on the Bill being dealt with by the Commons, probably in the early part of next week.

**Electrocution.**—An inquest was held the other day concerning the case of Mr. Alfred Edwin Grey, late an electrician of South Lambeth-road, London, the verdict returned being accidental death. The deceased was engaged in wiring a shop for electric lighting. It appears that after the installation had been completed and the current switched on—the voltage being 220—he was using a pair of pliers to cut the wire which was hanging from the casing when he fell back and expired. Medical testimony went to show that death was attributable to asphyxia. Some evidence given by the deceased's partner, however, tends to exemplify that the effects of electricity are psychical as well as physical. A voltage of 220 would scarcely cause death under normal conditions, but the last-mentioned witness stated that the deceased was always apprehensive of a shock from a live wire.

**Mineral Production in 1904.**—The statistics for 1904 relating to mines and quarries in the United Kingdom show that the total output of minerals at the mines under the Coal Mines Act was 245,775,315 tons, of which 232,411,784 were coal, 3,043,045 fireclay, 7,557,733 ironstone, 2,333,062 oil shale, and 429,691 sundry minerals. Adding 16,488 tons from open quarries, the total output of coal was 232,428,272 tons, an increase of 2,093,803 tons on that of the previous year. In 1903 the average output of minerals at mines under the Coal Mines Act was 359 tons per person employed underground. Last year the corresponding output was 361, an increase of two tons per man. The total output of minerals at the mines under the Metalliferous Mines Act was 3,246,336 tons, of which 1,603,855 tons were iron ore. The total quantity of stone and other minerals obtained from the quarries under the Quarries Act was 45,701,818 tons, of which 3,597,764 tons were iron ore. Adding to the produce of mines and of quarries over 20ft. deep 1,014,930 tons obtained from shallow open workings, a total output of iron ore of 13,774,282 tons is shown.

**Wireless Telegraphy on Trains.**—Having given evidence of its utility both by land and sea, it seems that wireless telegraphy aspires to enter other fields of commercial usefulness. In our issue of the 16th inst. we briefly chronicled the fact that the Chicago and Alton Railway had prepared a section of its system for the use of a wireless telegraphic device, with the object of exchanging signals between trains so as to avoid accidents. Recently a train running on this line kept in touch with the dispatcher's office by this means. The trial was so successful that the railway officials announce their intention of installing the system on their fast trains, and using it not only as an additional safeguard, but for transmitting commercial messages to and from passengers on the train. This use of wireless telegraphy for this purpose was suggested some years ago. It was, in fact, tried on one of the Canadian roads experimentally with reported success, but its adoption by the Chicago and Alton Railway is apparently the first attempt to put it to regular use. The movement of the trains may add difficulty to the scheme, but the distance to be covered will not be great, and reliability of service will be the primary consideration.

**Edison on "Wireless."**—The New York correspondent of the *Daily Telegraph* had an interview last week with Edison, who is credited with the opinion that radium is likely to be as cheap as coal "one of these days," and as to its possibilities, they defied imagination. Asked what he considered the most wonderful thing in the scientific world now being developed, Edison replied: "Wireless telegraphy, beyond doubt." He stated that the British companies were absolutely correct in adopting Marconi's system, and the feat of the Atlantic liners in maintaining communication with the shore throughout their journey was very remarkable. He believed that wireless telegraphy was still in its infancy, and that Marconi would perfect it within a few years. In a short time he considered that there would be no more difficulty in using a wireless system between New York and London than in using the cable. It should be just as easy to send 20 messages at once over wireless as it is now to send one over by cable, and at a rate of 1,000 words a minute. At the same time, he did not think the cables would be superseded by the wireless system. Business, he considers, will only be increased for both wireless and cable companies, just as the telegraph and telephone now supplement each other.

**The Commercial Status of the Nernst Lamp.**—At the recent Denver meeting of the American Electric Light Association Mr. E. E. Roberts presented a paper dealing with the results of a series of life and photometric tests of Nernst lamps recently made by the manufacturers. The method of making the tests and the photometer used

Digitized by Google

were fully described. During the life tests the lamps were operated under what is considered good maintenance conditions, the globes and holders being cleaned every 200 hours. The decrease in mean hemispherical candle-power amounted in 1,000 hours to 22 per cent., the greater part of which took place in the first 300 hours. The initial consumption per mean spherical candle-power was 3·31 watts, and per mean hemispherical candle-power was 1·95 watts. At the end of 1,000 hours the values had increased to 3·78 and 2·27 respectively. It is stated that, while the Nernst lamp properly belongs to the class of incandescent lamps, from the maintenance standpoint it is more akin to the arc. From the reports of the 7,000 glower units in service in the Pittsburg district it is learned that the total maintenance cost per glower per month is 9·56 cents, and it is estimated that the cost for maintenance per kilowatt-hour of energy used is 5·2 cents. This figure agrees closely with the average cost reported by a number of companies who use the lamp on a large scale.

**Royal Meteorological Society.**—The final meeting of this society for the present session was held on the afternoon of the 21st inst., Mr. Richard Bentley, F.S.A., president, in the chair. Mr. G. C. Simpson read a paper on the "Normal Electrical Phenomena of the Atmosphere." In no branch of physics, he remarked, has the discovery of ions, electrons, and radioactivity produced a greater revolution than in that devoted to atmospheric electricity. The author defined the chief line along which during the last few years investigations have been made and the conclusions arrived at, and pointed out some of the problems awaiting solution. The amount of radioactive emanation in the lower regions of the atmosphere is increased by all those meteorological conditions which tend to keep the air stagnant over the earth's surface. The meteorological conditions which either cause or often accompany stagnant air are calm, low temperature and high relative humidity, while, on the contrary, high winds, high temperature, and low humidity generally accompany the mixing of large masses of air. This all agrees with the observed facts that the atmospheric radioactivity increases with falling temperature, rising humidity, and increasing wind strength. The author is of opinion that a solution of the problems of atmospheric electricity can only be expected from the results of extended measurements in the atmosphere itself, and from laboratory experiments directed towards the problem. A paper by Mr. G. P. Ferguson, entitled "Two New Meteorological Instruments," was also read, in which the author described two new meteorological instruments: the "automatic polar star light recorder," for recording the amount of cloudiness at night; and the "ombroscope," an instrument for determining the time and duration of rain. Both of those instruments are in use at the Blue Hill Observatory, Mass., U.S.A.

**Wireless Telegraphy in Lightships.**—It is reported that the Board of Trade and Trinity House have concluded a contract with Marconi's Wireless Telegraph Company, Limited, providing for the installation of the Marconi system in lightships. The arrangement is expected to materially facilitate communication with the shore and between different lightships for the ordinary purposes of the lightship service, and also to report ships in distress. It is now more than six years since the Marconi Company installed wireless telegraphic apparatus on the East Goodwin lightship, and the communication that has been established with a shore station has apparently demonstrated to the satisfaction of the Board of Trade and Trinity House that good telegraphic communication can be maintained by these means. Communication was maintained for several months, during the latter part of which period the station on the lightship was worked by the lighthouse crew. The installation was found of great service to the lightship for ordinary communication, and on one or two occasions were of special utility in reporting damage from storms and in securing prompt assistance. When, after several months, it was found that the Board of Trade and Trinity House were not in a position to make a contract for the continuance of the arrangement, the apparatus was removed, the Trinity House expressing their satisfaction at the service rendered. Representations have from time to time been made to the Government by persons interested in the protection of shipping upon the desirability of effecting telegraphic communication between the lightships and the shore. Cable communication has, however, been found somewhat expensive and uncertain, and until recently various difficulties have prevented the Board of Trade and the Trinity House from concluding an arrangement with the Marconi Company for a wireless service. Apparently, however, these difficulties have now been surmounted, and presumably there will be an opportunity of testing the efficacy of the system for this purpose on a larger scale.

**The Efficacy of Advertising.**—Amongst the subjects that engaged the attention of the American National Electric Light Association at their recent Denver meeting was that of "Advertising Methods," a paper under this title being read by Mr. Percy Ingalls. Mr. J. C. Hammond, of the Denver Gas and Electric Company, opened the discussion, and stated that his company had not fallen below an advertising return of 10 per cent. of prospects. In some classes of advertising it had averaged 12 per cent., and in one particular class 63 per cent. Mr. J. F. Gilchrist remarked that in the branch of residential lighting the sale of current-consuming devices, such as electric heaters, etc., had increased 250 per cent. since advertising had been started. Mr. C. W. Lee recommended advertisers not to put all their eggs into one basket, but to spread their outlay over several organs, issuing varied matter at intervals of two or three weeks. In reply to a question, he stated that his company expends about ½ per cent. of its gross earnings for advertising. Mr. L. E. Watson stated that on particular days, and especially on New Year's Day, he sends out a neat letter to the business people of the town, setting out some point in connection with electric lighting. Mr. R. E. Allen related that when he took charge of the plant he now manages he began advertising to the extent of a full page weekly in each of the electrical papers, with the result that in two months the gross output increased by 40 per cent. as compared with the corresponding month of the previous year, while the output during the present year has increased by 55 per cent. compared with a twelvemonth ago. Mr. T. C. Martin suggested that part of the money offered to the association for advertising purposes should be expended in getting up albums containing samples of advertising in the form of circulars, "dodgers," follow-up letters, etc., these being circulated from one member of the association to another, such albums to be prepared once or twice a year. Our American friends are keenly alive to the value of the ad., and their ledgers generally reflect a favourable result at the end of the year.

**Trams over the Bridges.**—As the result of the City Corporation's decision, briefly chronicled in our last week's issue, and a conference between the House of Commons Committee and counsel for the Corporation and the London County Council another stage has been surmounted in the scheme for carrying the Council's trams along the Embankment, and it really seems now that the line will become an

Digitized by Google

accomplished fact, and that at no distant date. In the face of the conversion of the City Corporation it will be rather surprising if the Commons, or even the Lords, go back upon the decision arrived at in committee. The chairman of the special committee, Sir George Faudel-Phillips, gave the Corporation, in lucid terms, the reason why they considered the resolution previously arrived at should be rescinded on conditions to be agreed with the Council. The representatives of the latter, in an interview with the committee had fully recognised the rights and privileges of the City, and were agreed upon the desirability of the Corporation undertaking the widening of Blackfriars Bridge, while they were also prepared to meet the financial aspect of the question in a liberal spirit. Personally, he believed that trams along the Embankment would prove a boon to thousands. An amendment was moved by Mr. H. D. Kimber, who, while willing to assent to the proposal on suitable terms, considered the Corporation, before committing itself to any particular scheme, ought to be afforded an "opportunity of considering its feasibility, and all details involved, so as to adequately safeguard the position of the City as a county of itself, and as the tramway authority for such county, and also to protect the interests of the Bridge House Estates Trust." He was apprehensive of precipitancy, and considered that the scheme had been insufficiently discussed! Sir David Evans's objection to the motion was that if the Corporation reversed their earlier decision, they would discount their prestige at St. Stephen's. Sir William Treloar's objection apparently consisted of a protest against municipal trading. Mr. W. Cooper considered that, as the fringe of the City, the Embankment was just the place for trams, and Mr. A. H. Barber, a member of the special committee, submitted that if the Corporation steadily obstructed the scheme they would be denounced as a hopelessly antiquated body. After this the amendment was put to the vote, and was negatived by a majority of 31. A proposition was then adopted confirming the recommendation of the committee in favour of trams, with the alternative that a new bridge exclusively for trams might be substituted for Blackfriars, a satisfactory arrangement to be previously arrived at with the County Council as to construction, as well as to cost, management, control, and maintenance. These terms were submitted to the House of Commons Committee on Monday, it being agreed that the County Council should not, without the consent of the Corporation, make a commencement with any part of the line until Blackfriars Bridge has been widened or a new one constructed. Seemingly, it only remains now for the Corporation and the Council to agree upon terms, and as the well-loaded coffers of the Bridge House Estates will be largely available for the work of widening the existing bridge or building a new one this should not prove a very difficult matter.

**The Telephone Transfer.**—The enquiry by a committee of the House of Commons into the merits of the provisional agreement between the National Telephone Company and the Postmaster-General was resumed last week, when Bailie Stevenson, of Glasgow Corporation, who had also been requested by other telephone-owning corporations to state the case for municipal telephony, proceeded to state it at considerable length. Coming to the immediate question of the agreement, he gave it as his opinion that the question of whether it was in the public interest must be answered in the negative, except under the following circumstances: (*a*) Unless the plant is purchased at a cost not greater than the expenditure which would be required to enable the Postmaster-General to put equally good plant in position by the end of 1911. The experience of the municipalities showed that, apart from London, all the plant required throughout the country could be installed in three or four years. There was, therefore, no immediate urgency for completing the agreement. If the company was unwilling to make the modifications necessary to prevent the price paid being excessive, the matter could well stand over for a year or two for further negotiations. (*b*) Unless the Postmaster-General could show that the result of the purchase would be a cheaper and more efficient service. The evidence given before the committee, however, led him to a contrary conclusion. Returning to the municipal aspect of the question, he considered that the development of telephony on a huge scale, and the varying conditions prevailing in different parts, would render it exceedingly difficult for the whole service to be adequately performed by one central authority, which was an argument against nationalisation. On Tuesday Alderman Carden, ex-chairman of the Telephone Committee of the Brighton Corporation, gave it as his opinion that local authorities would be able to manage local telephone services better than the Postmaster-General. Alderman Southern said the Manchester Corporation were of opinion that cities and towns which had not established a telephone service should not be placed at a disadvantage in the future as compared with places which had such a service. Though he could not point to anything in the agreement which prevented the establishment of new municipal services, he apprehended that a policy of discouragement would be pursued. He thought, with other witnesses, that local services should be managed by the local authorities. Mr. A. R. Bennett emphasised the grave significance of the schedule for minimum charges which the transfer agreement proposed to authorise. Under the minimum schedule the National Telephone Company would be legally entitled to lease telephones at a cost of only 20s. per annum. That amount would be altogether unremunerative. As corporations necessarily had to charge remunerative rates for telephones, the sanction given to that and other unremunerative rates in the schedule must prove destructive to the corporations businesses. Another charge sanctioned which was also unremunerative was the charge of £2. 2s. per annum rental and ½d. for each outward call for a direct exclusive line. The committee will sit again on July 3, when the evidence for the London County Council and the City Corporation will be heard.

**Income from Patents.**—The report of the committee appointed to investigate the question of income tax assessment has been issued, and one section at least will be read with interest by inventors. The committee have not apparently much sympathy for the spirit of genius, as the paragraph is prefaced by the statement that invention "is usually accidental in its manifestation," and when it leads to patent rights with a marketable value the sale of them has but little of the character of annual income. The profits from patents may be received in various ways, but the patentee who does not himself work his patent usually receives his remuneration in one of the two ways of "royalty" or "lump sum payment." Where a royalty is paid the income from it is assessed in the hands of the patentee, the user of the patent treating the payments made by him as trade outgoings. Where the user of a patent purchases it outright the transaction is treated as a capital transaction on both sides, and no assessment is made on the original patentee in respect of the lump sum received by him. At first sight it may appear that this results in relieving the original patentee of income tax on a profit or gain that would seem to be taxable. Such, however, is not really the case, seeing that as the purchaser

Digitized by Google

of the patent is purchasing an income on which he will have to bear the whole of the tax, he presumably takes that fact into consideration when fixing the amount of the purchase money, and gives so much less in consequence. The case is, in fact, analogous to the numerous other cases, such as sales of leasehold interests, of annuities, and so forth, in which a future income is discounted and assigned to a purchaser in exchange for a present capital sum. In theory, the committee say it might be economically possible to treat the sale outright of a patent right in the same exceptional way that the sale outright of a copyright is now treated for the purpose of assessment to income tax. But the present law does not admit of this course, and in practice it would be exceedingly difficult and complicated, and there would be great uncertainty about collecting the revenue on the several occasions on which a patent might pass from one holder to another. The committee, therefore, cannot recommend that any change should be made in the present method whereby the whole of the profits derived from the working of a patent are charged upon those profits at their first source—viz, as earned by the user of the patent, leaving the distribution of the burden of the tax, as between the vendor and the purchaser of a patent, to be regarded as one of the elements of the bargain between them. They do, however, recommend that the principle of taxation of income at its source should be applied to all forms of profit derived from the working of patents, and consequently that, even where a patent is worked under a license or royalty, the manufacturer using the patent should be directly assessed on the whole of his profits, including those derived from use of the patent, but with a title to deduct tax from his payments of royalty to the patentee. The report remarks that this method, besides being more consistent with the general principles of assessment under the Income Tax Acts, would secure collection of the tax on the profits derived from the working of patents in the United Kingdom but payable to patentees who reside abroad and have no agent resident in this country.

**Acyclic Dynamos.**—A patent has recently been granted in the United States to Mr. J. E. Noeggerath, of Schenectady, for an acyclic dynamo, which is stated to embody the latest phases of its development. Its simplicity of construction and the consequent absence of commutation troubles render the acyclic or homopolar dynamo especially suitable for operation at high speeds, while the machines may be designed to develop readily at high speeds the necessary counter E.M.F. for operating at ordinary voltages. Mr. Noeggerath's invention consists in so arranging the connections between the armature conductors and the stationary conductors of the machine that these connections themselves serve to magnetise the machine, and that by varying the effective length of these conductors the field strength may readily be varied. This variation may be obtained by simply shifting the position of the brushes relatively to the stationary conductors. In the first diagram, which shows a side elevation partly in cross-section of a unipolar machine arranged with adjustable brushes, A represents the armature and F a structure that corresponds to the field. An armature conductor, *a*, is preferably formed as a flat strip held in place by a cylindrical binding ring, *b*. The armature conductor, *a*, is connected at each end to collector rings, C C; B B representing brushes bearing on the collector rings and mounted on bars, D D, which are carried by the adjustable rings, E E. These rings are mounted in the manner ordinarily employed for brush-holder yokes, enabling the rings to be rotated so as to shift the position of the brushes. A return conductor or frame conductor, *f*, is employed, by means of which any two brushes at opposite ends of the machine may be connected so as to place two armature conductors in series. The frame conductors are formed in the same shape as the armature conductors, and as they are adjacent to the latter, and are carrying an equal amount of current in opposite direction, they serve to neutralise the armature reaction. It will be seen from the second diagram that each brush instead of being connected to the nearest frame conductor is connected by a flexible connection, *h*, to a frame conductor, *f*, which is slightly displaced from the brush. The several flexible connections, taken together, form one or more complete turns encircling an armature and carrying a

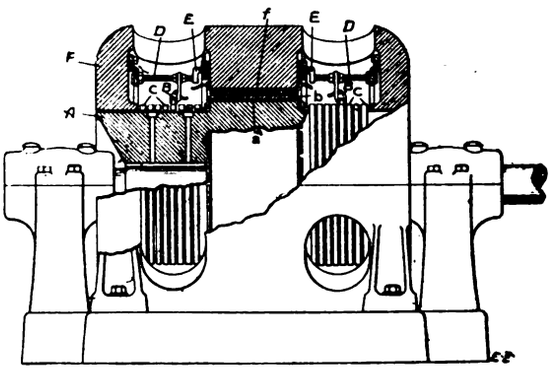

FIG. 1.

current equal to that in each armature conductor. Reference to the first diagram will show that if a coil were placed outside of and parallel to a collector ring, and energised by by a current, it would set up a flux, which would pass down from the central portion of the frame across the central air-gap of the machine into the armature, cutting the armature conductors, then outward to the end of the armature, and across the outer air-gap to the end of the frame, thus generating an E.M.F. in the revolving armature conductors. It will be evident from the second diagram

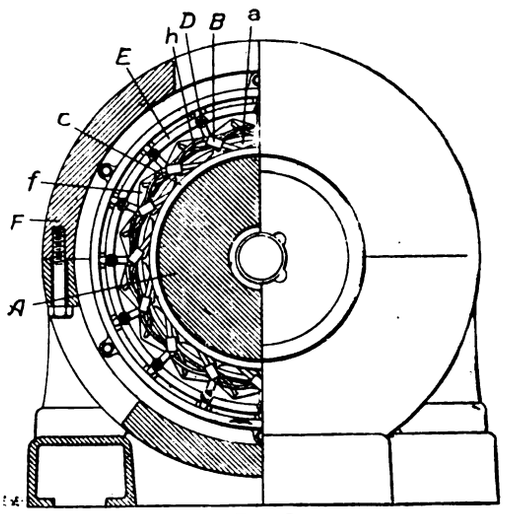

FIG. 2.

that the flexible end connections form such a magnetising coil, and as the end conductors carry the armature current the dynamo will act as a series-wound machine, and as a motor will exhibit the characteristics of a series motor. Furthermore, it will be seen that by shifting the brushes in one direction or the other the effective length of each flexible conductor, and consequently the effective turns of the field, will be varied. This furnishes a convenient means for controlling the speed of the motor or for reversing the direction of rotation. The excitation produced by the end connections can, if desired, be supplemented by a field coil, but for high speeds the end connections themselves will usually be found to provide sufficient excitation.

## INCORPORATED MUNICIPAL ELECTRICAL ASSOCIATION.

The tenth annual convention of this association was opened in Edinburgh on Tuesday last, when the LORD PROVOST (Sir Robert Cranston) welcomed the members. He wished them a pleasant and profitable time in the city of Edinburgh, which he claimed was unequalled for historic interest. They were in Edinburgh proud of their electrical department, which held no mean place amongst municipal undertakings. He extended a hearty welcome to them on their own account, as he was pleased to have Edinburgh chosen as the meeting place of such an association; he also welcomed them because they had selected as their president Mr. F. A. Newington, the city electrical engineer. He was pleased to see with them that day Bailie Mackenzie, who was the originator of the Edinburgh undertaking. After some amusing remarks as to the accuracy of electricity meters and the distribution of profit of the electrical undertaking, the Lord Provost concluded his speech by wishing the convention every success.

Councillor STEVENSON, the chairman of the Electric Lighting Committee, hoped that the Edinburgh visit would be a profitable one. They were fortunate in having as Lord Provost Sir Robert Cranston. He would be pleased to show them the electric lighting undertaking, which in Edinburgh had been a conspicuous success. It was inaugurated 10 years ago, and in the first year's working they secured 450 consumers and sold 880,000 units. Last year there were 8,000 consumers on the mains and they sold 11,000,000 units. They had laid up a reserve fund of £78,000, and had an annual income of £112,000. The policy of the committee was to reduce the charges as quickly as possible, and they now charged only 3½d. per unit for lighting. From the commencement of the undertaking there had been no difficulty in making a profit, but they had had a fight to keep this profit out of the hands of the city treasurer. He believed that after building up a reserve the profit should be used to reduce charges rather than go to reduce the general rates. He extended a cordial welcome to all present.

Mr. F. A. NEWINGTON then read his presidential address.

### Presidential Address, 1905.

BY FRANK A NEWINGTON, CHIEF ELECTRICAL ENGINEER, EDINBURGH.

I have to thank you for the great honour you have done me in electing me your president for this year. This is our tenth annual meeting, and it is interesting to note the increase in membership since the formation of the association. In the first year our members were: representatives of committees, 39; engineer members, 48; associates, 36; and now they are: committees, 148; engineer members, 159; associate members, 13; associates, 71. That is, our membership has increased nearly four times during this period.

Mr Arthur Wright, in his presidential address at the first annual meeting, expressed the opinion that there was a pressing need for an association of this kind, and the rapid rate at which we have grown proves that he was correct. It will, perhaps, not be waste of time if we look back at some of the points raised by our first president, and see what has been done during these 10 years. The period for repayment of loans has been very carefully considered, and this association has come to the conclusion that about 30 years is the average life of electrical plant There is, however, still no standard period for repayment. Quite recently the Local Government Board has granted loans on what appears to be far too short a term for repayment. This matter will be brought before you at the general business meeting on Friday, so that some concerted action may be taken.

The methods of dealing with the profits of electricity supply undertakings is still a difficult question. In the event of the general rates not being sufficient to meet the expenditure, it is a very easy way out of the difficulty to take a few thousand pounds of the surplus of the electricity undertaking, and so save an increase in the rates the following year, but this seems to be a short-sighted and dangerous policy, at any rate until the full statutory amount of 10 per cent. of the capital expended has been placed to the reserve fund. And, further, unless a similar sum is contributed by the gas undertaking it is unfair. It does not seem right for the users of electricity to be asked to assist the users of gas to pay their rates. This is really what it amounts to. If electricity was universally used, a contribution to the rates, although undesirable, would then be borne more evenly than under present conditions. Perhaps with a tramway undertaking it is rather different, as at present there is not, as a rule, any direct competition, but even here it seems that the poorer part of the population—that is, those who most use the tramways—are being asked to bear part of the taxation of the rich. The other side say that, as any loss would have to be borne by the rates, it is only right that the undertaking should pay something for this security. But is there much in this argument? As a rule, the undertaking pays its way after the first year or two. Although the majority of undertakings are building up their reserve fund as quickly as possible, still it seems that we are not any nearer to a fixed rule about this than we were 10 years ago.

Depreciation of plant is closely connected with the reserve fund. If the loans are paid off in 25 or 30 years, and the reserve fund is made up to the full amount, is it necessary to further depreciate the plant This largely depends upon the life of the plant, and if this will on the average last the period of the loan, there does not seem to be any need of a depreciation fund as far as the life of the plant is concerned. Municipal undertakings in this respect are working under different conditions to companies. Electricity supply companies have a definite number of years—42 in most cases—during which they are given statutory powers to supply electricity in a given area, but at the end of that period the local authorities can buy up the undertaking, not as a going concern, but simply at the then value of the plant—that is, the business connection which the company has built up during these years, or goodwill, is not worth anything. Now, consider a municipal undertaking. The capital has to be paid off in from 25 to 30 years as a rule. At the end of this period how do we stand Buildings will still be quite good; the copper in the mains will be of very considerable value even if the insulation is not, and if our machinery has been kept in good order by general maintenance and perhaps by calling on the reserve fund for special cases, our successors will be in the very comfortable position of having a good business bequeathed to them along with a very considerable amount of plant without having to pay anything for it. The loan having been paid off they will be free to borrow again to replace machinery if necessary. Moreover, if the local authority at any time during the period of the loan or after is desirous of selling the undertaking, judging from towns where the local authority has purchased from a company, they will be able to command a very considerable sum for goodwill. It seems, therefore, that the local authorities are very much better situated in this respect than are companies.

There is another side, however, to this question of depreciation which must be kept in view. It would be very unwise to say that the type of machinery in use to-day will also be installed 20 or 30 years hence. But unless some entirely new method of generating electricity is discovered, any improvements that can be made in either steam or gas engines would not warrant the displacement of the present very efficient steam-engine. With coal costing about ¼d. per unit (and this figure we are all gradually reaching) enormous economies would have to be obtained with any new method of generation before it would pay us to do away with our present machinery. But we must not forget that we may have to face some altogether new form of artificial illuminant, and, therefore, it would seem a sound business policy to form a depreciation fund over and above the reserve fund in order to meet an emergency of this kind. At the start of an electricity supply undertaking the output is frequently underestimated, and so small units of machinary are put down. After a few years these are found to be inconvenient to work, although still quite suitable in other respects. Second-hand plant of this kind seems to have an extremely small value—in fact,

Digitized by Google

very little more than the value of the material—unless a purchaser can be found who wants exactly this kind of machinery. Plant of this description, therefore, may depreciate in value very rapidly. This also should be provided for by means of a depreciation fund.

In connection with the finance of municipal electrical undertakings, it is exceedingly satisfactory to notice how many more towns are now making a profit, and in many instances large profits, as compared with a few years ago. In the table of costs in the *Electrical Times* of May 25, 1905, the number of municipal electric supply undertakings, not including tramways, making a profit is 115, the surplus being about £436,000. Those showing a loss are 67 in number, the amount being £69,480. Of these 67 towns, 42 have only completed their third year of working. The figures given in the table of costs for a corresponding date in 1902 are 46 towns with a surplus of about £89,000, and 53 towns with a loss of £86,500. Gas experts have succeeded in very much improving the incandescent gas mantle, so much so that it is now very suitable for the lighting of streets where a large amount of light is not necessary, and where, therefore, arc lamps would be too powerful. Just at present there does not seem to be any form of electric lamp that can quite compete with the incandescent gas mantle for this purpose. There are some new forms of electric lamps, more or less in the experimental stage at present, that appear to be very promising, as they are exceedingly economical. We may, therefore, very soon expect to have a lamp that can be used for side-street lighting at a less cost than the incandescent gas mantle. The paper on street-lighting that will be read this morning is of special interest to us just now on account of the recent improvements in the gas mantle.

During the last 10 or 12 years enormous improvements have been made in the manufacture of machinery for generating electricity, but, unfortunately, very little, if any, advance has been made in the wiring of houses or other buildings for electric light. This work, as a rule, does not come directly under our care, but it is a matter that may very seriously affect us. The poor quality of the material used and the unsatisfactory way in which the work is carried out, are certain to give trouble. So-called indiarubber insulation for electric conductors frequently contains from 50 per cent. to 60 per cent. of something that is not rubber at all. The elastic properties of this mixture soon disappear, and it becomes hard and brittle. If there is any moisture in the pipes the insulation fails, and then the house has to be rewired. What will be the result of this? Will the consumer be content to be frequently having some of his lamps out of order, and after a period of, say, 10 years find it necessary to rewire his house? Will he not rather be inclined to think that electric light wiring and fittings are too uncertain and expensive to keep up, and so go back to some other form of artificial illumination? The material now very generally used for insulation is not nearly so good, on account of the high price of rubber, as that employed 10 years ago. Contractors for electric installation work naturally buy the cheapest material they can, especially as competition in this class of work is very severe, but, as a rule, they have not any idea of what the insulation is composed of, nor have they the means of testing it. They simply trust to the makers of insulated cables to provide them with material that will pass the official test made by the supply authority. As iron pipes are now very generally used for protecting the wiring, a better insulation for the conductors is required than in the days when wood casing was practically the only material used. I do not suppose that the larger users of electric light would discontinue it on account of these troubles, as its convenience and other advantages will with them outweigh these, but to the consumers using only a few lights the expense of rewiring their houses might be a very serious matter. As these smaller consumers are probably more profitable to us than the larger, it will be to our advantage to do all we can to improve the existing unsatisfactory way in which this work is done. We do not want to increase the cost of installing electric light, as this would prevent the smaller householders from using it. If possible, we should try to make it less costly. For small houses where exposed wires would not be objectionable is there any need for iron pipes or other expensive protection for the wires? During the last year or two fire-proofed cables have been introduced. As a rule the fire-proofing is quite efficient, and as far as can be seen at present does not have any harmful effect on the rubber. A system in which fire-proofed cables are used, carried on suitable insulators fixed to the walls or ceilings, should be perfectly good. The insulation of the cables would require to be of high quality, and good workmanship would be necessary, but the cost should be considerably less than with the present system with poor quality material. The rewiring of this when necessary would also be an easy matter. On the Continent it is usual to see ordinary twin flexible wires fixed to the walls, often without insulators, and these do not seem to give trouble. The pressure there is lower than is generally used in this country, but with good material and workmanship this system should be quite suitable. The cost of installing electric light is a very serious consideration to the small householder. That this is realised is shown by local authorities themselves wiring houses on what may be called easy payment terms. Whether this is advisable or not is a question that I will not deal with now, but I think that everyone will agree that it is better for the undertakers not to do it if the consumer will. By reducing the cost of installation work this end may be attained.

The present position of supply authorities as regards the power to enforce wiring regulations is vague and unsatisfactory. On account of the use of inferior material and of bad workmanship fires have occurred through electricity. This, in time, may shake the confidence of the public in the safety of electric light. In the Electric Lighting Acts, and also in most provisional orders, there are clauses which may be taken to give the undertakers the necessary powers to enforce good work. But as these are not so definite as might be desired, your council are now considering this matter with the view of asking the Board of Trade to sanction wiring regulations which will, as far as possible, ensure the safety of the public from the risk of fire.

The president last year referred to the testing of consumers' lamps. This has been taken up very energetically by Mr. Wilkinson in Harrogate, who has made arrangements so that consumers or contractors can have their lamps tested at a nominal charge. Although testing the lamp when new will not prevent the consumer from using it after its useful life is past, it will at any rate insure that the lamps when new are efficient. This seems a simple way to prevent the consumer buying low-priced inefficient lamps, simply because they are cheap at first. I think the majority of users of electric light will be very glad to buy lamps that have been tested and certified by the corporation. This matter is now being carefully considered by a committee of this council, and suitable rules and conditions are being drawn up which will be issued very shortly.

One of the aims of a municipal electrical undertaking is to utilise the machinery during the daytime as much as possible, and, therefore, electricity for power or heating purposes is sold at a low rate. But there is a weak point in this arrangement. The motors are used during the time of maximum lighting load during the winter months, and, therefore, additional machinery must be provided for them. If we can arrange for the motors to be switched off during the two or three hours of maximum load for lighting in the four winter months, extra machinery will not be required, and so a very low rate can be charged. This system is just now being adopted in Endinburgh, and is also in force in a few other cities. On analysing the consumption of electricity by motors, it is generally found that the load factor is extremely low. The following figures show the average number of hours a day during which the total power installed is used for different classes of work in Edinburgh.

| | Total H P. installed. | Full load. Hours per day. |
|---|---|---|
| Elevators | 610 | ·9 |
| Butchers and bakers | 180 | 1·27 |
| Printing works | 1,327 | 1·52 |
| Breweries | 247 | 1·13 |
| Joiners and builders | 1,057 | 1·85 |
| Engineering works | 981 | 2·08 |
| Laundries | 40 | 2·87 |
| Aerated water works and bottling stores | 88 | 3·27 |

Digitized by Google

Unfortunately these figures refer to kilowatts installed, not to maximum kilowatts required, but they show that the whole plant would only be used for an exceedingly short time each day. From these figures it is quite certain that the total power used at any one time is not half the power installed, and so the hours per day can at least be doubled, but even then the load factor would not be good. As the cost of generating electricity will be in inverse proportion to the load factor of the motors, this should be considered when fixing the price of electricity for power purposes. The above figures are not of very much value, because they do not tell us how much of the motor load overlaps the lighting load. In connection with the large Power Bill now before Parliament a good deal has been said about the diversity factor, but is this not over-rated. As a rule, factories shut down at about the same hour, say, six o'clock in the evening, and probably the motors are in use more or less up to the time of stopping.

In conclusion, I would suggest that the members of this association would be collecting very valuable data if they could find out how the motors connected to their system are used during the hours of maximum lighting load in the winter months.

---

Alderman ELVY ROBB, of Tunbridge Wells, proposed that a vote of thanks be given to Mr. Newington for his interesting address, which touched on a wide range of subjects in a most temperate and useful manner. The subjects were of interest to all, and the president's treatment was eminently fair.

Prof. A. B. W. KENNEDY had pleasure in seconding the vote of thanks, and congratulated the president on the sound common sense displayed in the treatment of the thorny points in the address. He thought that those present would, on the whole, agree with the conclusions come to.

The President then called on Councillor Sinclair, of Swansea, to read his paper on

## Load Factor—Its Effect upon an Electricity Station.

BY COUNCILLOR ALEX SINCLAIR, CHAIRMAN OF THE ELECTRIC LIGHTING AND TRAMWAYS COMMITTEE, SWANSEA.

In compiling this paper the author keeps in view the great importance which the load factor of a station has upon its commercial success, not that it is at all necessary to labour this point as far as engineers are concerned, for he feels sure everyone fully realises the immense possibilities to their stations if a high factor can be ensured; his object, however, is not so much to impress engineers, but to attempt to bring before the notice of the chairmen and their committees the necessity of improving their position in this respect. Although lighting was in the first instance the reason for establishing an electricity under-

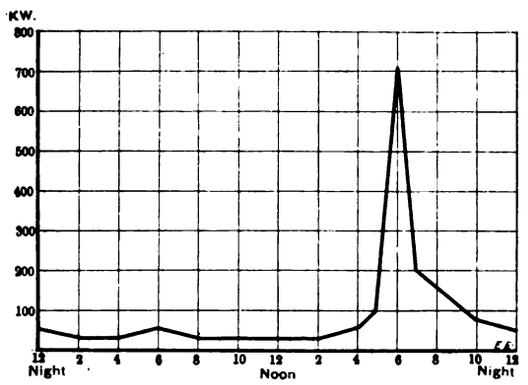

CHART NO. 1.

taking, it is generally conceded that this alone can only hope for a certain measure of success. Of course, very large stations with large outputs do not come within this category—and, successful as many have been, they cannot, on lighting alone, hope (no matter how they increase) to add much to their prosperity. By adding customers who will take energy either for power or other purposes during the hours of light load the load factor is improved, with a result that the cost of generation per unit becomes decreased. Among desirable customers to assist in attaining this end are public lighting, power and heat, and tramways, but there are also others of great importance, such as supply in bulk, small cottages, etc., but for the purpose of this paper it is the writer's intention to deal only with those enumerated. For simplicity he divides his remarks into two parts: the first dealing with the station itself, and the other with the commercial aspect.

A series of charts is submitted to illustrate graphically the effect attained by incorporating the classes of supply mentioned

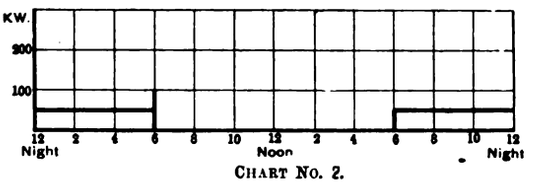

CHART NO. 2.

with the ordinary lighting. These charts are neither in any way typical of any station nor ideal, but simply form an illustration of what might be done in common practice in a town of 100,000 to 150,000 inhabitants and a station of 1,500 kw. to 2,000 kw. They do not interpret the load on any particular day of the year, but what might be termed the average loads of 365 days reduced to one, but with, in each case, the maximum kilowatts reached. Of course the usual irregularities of the

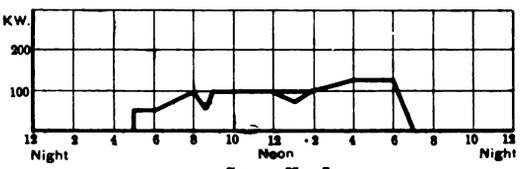

CHART NO. 3.

daily curves are left out, and the figures, like the charts, are merely illustrative. Chart No. 1 supposes an annual output of 613,200 units with a maximum load of 700 kw. for private lighting. The load factor on this supply would be

$$\frac{613{,}200 \times 100}{8{,}760 \times 700} = 10 \text{ per cent.}$$

It will be noticed that, notwithstanding this high maximum demand—the time of the demand is limited and the rest of the

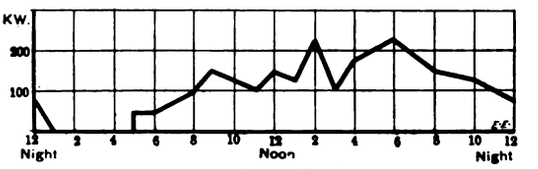

CHART NO. 4.

day the load is light—to supply a large number of customers with light during the early hours of darkness requires 10 times the machinery that would suffice to supply energy to the same amount during the 24 hours. Further, it will be seen that, adding to lighting customers only, will surely add to the height of the peak without materially filling in the rest of the diagram.

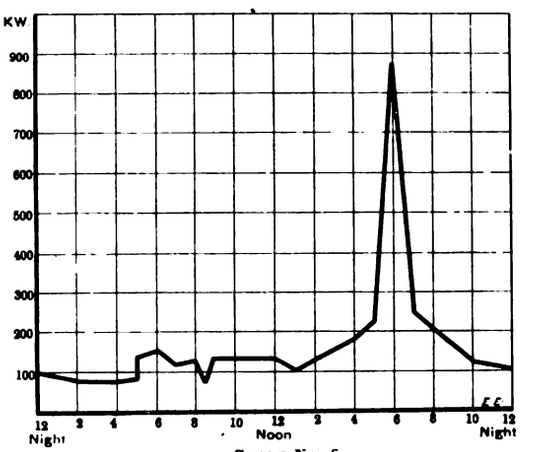

CHART NO. 5.

Chart No. 2 illustrates a public lighting supply giving an annual output of 219,000 units with a maximum demand of only 50 kw. This would give a load factor of

$$\frac{219{,}000 \times 100}{8{,}760 \times 50} = 50 \text{ per cent.}$$

It will be readily seen that with so small a plant capacity giving such a large output, the position of the station must improve. Charts 3 and 4 refer to power and traction, giving a supply of 459,000 units with a maximum of 125 kw. and 916,370 units with a maximum of 225 kw. respectively; their

Digitized by Google

load factors are 42 per cent. and 47 per cent. These further illustrate the improvement to a station already related in the remarks *re* public lighting. Chart No. 5 shows the combination of lighting (private and public) and power, whilst No. 6 depicts the same with traction added. In the first example, with 1,281,200 units and a maximum demand of 875 kw., the load factor is increased to 16·71 per cent., whilst in the other, having 2,207,570 units at 1,100 kw., the load factor becomes 23·14 per cent.

The question now arises as to what is the commercial value of the foregoing, but before doing so fully it will be necessary to show what is the likely result of improved load factor on the cost sheets of the station. For this purpose, after much study

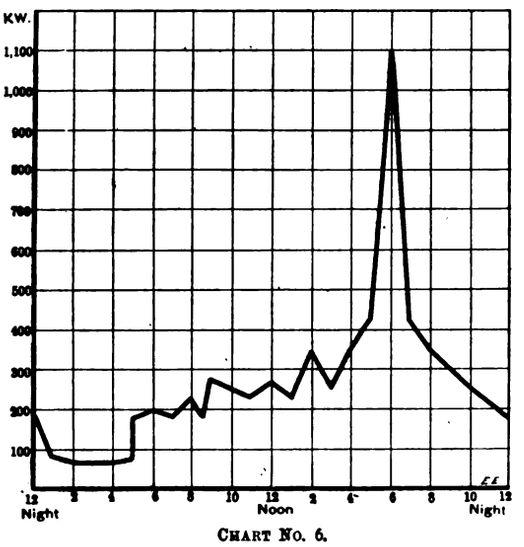

CHART No. 6.

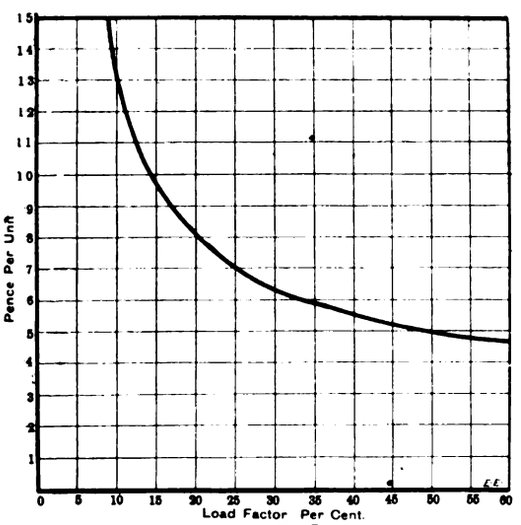
and considerable experience, the author has compiled a series of curves showing cost per unit under varying load factors; these must not be taken as indicative of either the relatively good or the relatively bad, or to the very large or very small stations, nor of any particular one, but may be applied to all, correcting for variations due to locality or other cause. Curve No. 7 is intended to illustrate the works cost under different load factors; the cost per unit in pence can from this curve be readily ascertained for any factor from 8 to 60 per cent.; it is made up of station charges for coal, wages, repairs, oil, stores, etc., but as the figures are reasonably within ordinary results, it is not necessary to comment thereon. Curve No. 8 is an effort to depict the total charges—*i.e.*, works cost plus management, rent, rates, taxes, insurance, etc., in pence



CURVE No. 7.

per unit for factors ranging from 8 to 60 per cent. In compiling Table A the author has not so much in mind the proof or otherwise of the correctness of his figures, nor to show how closely they approximate to average practice, but to impress more particularly the great improvement in cost due to increased load factor. In arriving at these figures he noticed considerable variations in the amounts charged by different stations for management, rent, etc., such variations differing from £610 in a 1,000-kw. to £2,000 in a 1,200-kw. station; these figures are taken at random from the *Electrical Times* to illustrate the great lack of uniformity in this direction; this variation is no doubt due to the policy of the particular place or district, but for the purpose of making strict comparisons greater uniformity might be arrived at; further, it is

Table "A" giving Cost with varying Capital Charges per Kilo-Watt of Maximum Demand.

| Load Factor. | Cost per Unit. | | | | | | | | |

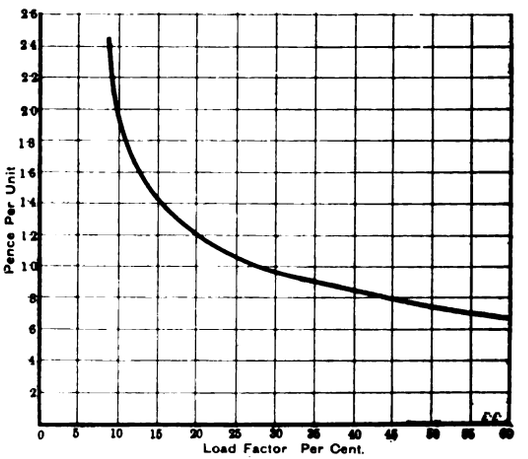
the author's opinion that these charges should be properly allocated so as to approximate to the position a similar undertaking would hold were it owned by a private company, and so prevent criticism often levelled at municipal accounts. In Curve 9 will be found the cost per unit in pence under different load factors for total costs plus interest and sinking fund; for the purpose of this curve an average capital expenditure of £120 per kilowatt of maximum demand has been taken and the calculation worked out on the basis of 5¼ per cent. for interest and sinking fund. For



CURVE No. 8.

simplicity the author has tabulated in Table A the results obtained in Curve 9, but with capital charges rated at from £80 to £140 per kilowatt of maximum demand. In allocating to each unit, irrespective of its use, its due share of capital charges, he will, no doubt, be subject to severe criticism, but he is of opinion, after serious consideration, that such is only fair and proper. True, such a proposition contains a weakness which may be illustrated by the absurd example of 24 persons taking each one unit per day, but consecutively hour by hour, through the same day. In the one case collectively their load factor would be 100 per cent., but individually it would be only 4·7 per cent., whilst the one person would be the same as the 24 collectively. The financial result, however, would probably be 24 units at, say, 6d. and 24 units at, say, ¾d. for prac-

tically one and the same thing. Such a condition of affairs can only be imagined, for in practice these things generally average up, and it is, indeed, the purpose of this paper to bring home the great advantage of accumulating customers for all times and purposes, so that the load factor may be improved. The figures above quoted, as already pointed out, are not symbolic of any particular station, but taken as a whole, they will be found to coincide fairly with modern practice, as is demonstrated in Table B.

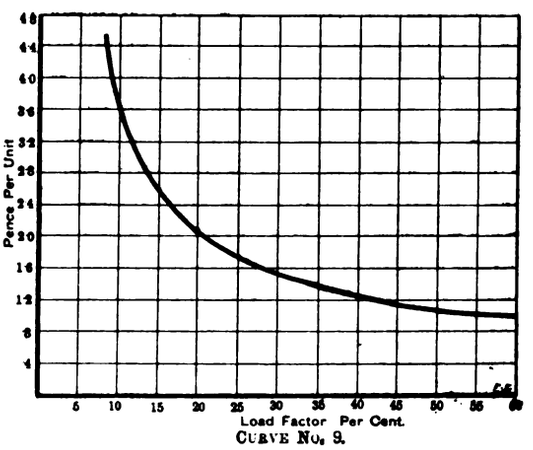
Now as to the commercial advantage likely to accrue from improved load factor, it is only necessary to take the earlier examples as shown in Charts 1, 2, 3, 4, 5, and 6 in combination with No. 9. It will be noticed that for private lighting alone each unit costs at 10 per cent. load factor, 3·595d.; public lighting alone with 50 per cent. load factor, 1·072d.; power alone with 42 per cent. load factor, 1·2d.; traction with load factor of 47 per cent., 1·1d.; whilst the four combined, with a load factor of 23·14 per cent., costs only 1·835d., or practically half the cost for private lighting alone. As to the reliability or otherwise of these figures, and assuming for the moment they represent the revenue per unit, they should give on the collective load factor a similar amount as on the individual load factor. For this purpose are again taken the figures of the earlier illustrations—viz. :

| | | | |
|---|---|---|---|
| Private lighting, | 613,200 units at | 3·595 | £9,185 |
| Public ,, | 219,000 ,, | 1·072 | 978 |
| Power | 415,000 ,, | 1·200 | 2,075 |
| Traction | 916,370 ,, | 1·100 | 4,200 |
| | | | £16,438 |

whilst collectively the result is

2,163,570 units at 1·835d. ..... £16,502

The author thinks it plain from his remarks that it is essential to the cheap generation of electricity to increase the load factor of a station by every possible means, and he has tried to prove that this can be done by pushing vigorously the different kinds of business enumerated. To sum up, he would advise, first, the increasing of the ordinary lighting load by systematic canvassing, thereby bringing before the notice of probable consumers in an attractive form, by booklet or otherwise, the great advantages of electric lighting over other forms of illumination ; lighting is mentioned because, although an increased lighting load does not materially decrease the cost per unit, still the larger the output the better it is for the general welfare of the undertaking. Secondly, public lighting should be extensively used, for by its use the financial position is so improved as to allow energy to be sold at cheaper prices ; Edinburgh and Glasgow may be cited as typical examples of the fruitfulness of this supply. He also is of opinion that this point does not always receive its due consideration by electric lighting committees, and where it is tried, more or less extensively, its progress is often throttled by the charge per unit being too high, thus affording adverse comparison with other forms of street illumination. It has been made clear in the course of this paper how cheaply energy can be generated when so valuable a load factor as that of street-lighting can be obtained, and the writer thinks that this matter should receive far more attention in the future than it has had in the past. Thirdly, and on this point he lays particular stress, that great hopes may be held out for the future of stations by dispensing power on a large scale to small users at cheap rates. There are many towns where there are small users of power, such as timber yards, printing establishments, machine shops, etc., at present using steam or gas driven plant, where electricity would prove more efficient and economical. Where powers are held for the hiring out of motors this class of consumer is making great headway, because many view with much apprehension the scrapping of their present plant and substituting electricity with what they think the possibility of failure, when they know that by hiring a motor their liability—should they wish it—ends with the year they are more prone to enter into a trial in what they consider to be more or less an experiment. The experience in this direction in Swansea has been to add very largely to the business, and to some extent to account for its successful running. In two years we have improved our load factor from 12 per cent. to nearly 18 per cent., and the author may here add that it is to this circumstance the title of his paper owes its origin. Lastly, with regard to traction, it is not many stations which are so fortunate as to have this valuable asset, but the experience of those having such a load is quite sufficient to demonstrate its help in producing excellent results. He



CURVE No. 9.

refrains from expressing an opinion as to the wisdom or otherwise in having two distinct stations, the one for traction and the other for lighting, etc., as he does not think it comes within the scope of this paper, but it is evident from what he has brought before you that the addition of a traction load to its other functions is of immense advantage to the undertaking.

There is another feature the author has not yet touched upon, but the close study of this question has fully confirmed his belief that electricity cannot be purveyed like milk or sugar at so much per quart or pound ; in other words, an uniform price per unit cannot be fixed, but must depend on the nature of the supply—*i.e.*, quantity and load factor. The maximum demand system meets the requirements of the case, but unfortunately its explanation is so complicated to the ordinary individual that he either cannot or will not try to understand it. The author would like to throw out a suggestion which may or may not bear fruit. If a system simple in itself could be arrived at whereby a customer's load factor could be readily and easily ascertained, his charge per unit could then be regulated by a discount on its rated price. By some such means the ordinary customer, usually a man of business, would be appealed to because he would readily accept the situation if he is aware that his account is subject to a discount on the quantity (as gauged by his load factor) of energy he uses, whereas when confronted with the complex explanations of the maximum demand, he is amazed, always confused, and, if his bill be high, never satisfied.

In conclusion, the author once more wishes to impress the fact that his remarks are intended to place before the chairmen of committees in a concise form the obvious advantages which are sure to follow an improved load factor. Although he has brought forward nothing new, nor, he hopes, anything of a very controversial character, he is of opinion that the criticisms which will follow in discussion will be generally helpful to the carrying on of municipal electric undertakings. Before concluding, he would like to record how highly he appreciates the valuable information contained in the supply costs and records

Digitized by Google

of the *Electrical Times*, and also his best thanks to those engineers who, at much trouble to themselves, accorded him great assistance.

Mr. J. F. C. SNELL, of Sunderland, opened the discussion on the paper, and commended the author for the concise way in which he had explained the advantages of improvement in load factor. It would help chairmen of committees to follow by means of the curves given the evolution of the load factor of a station supplying power, traction, and street-lighting from the curve for a station with private lighting only. He did not agree with the author on one or two points. Thus the power factor of public lighting he found to be from 20 to 24 per cent., instead of 50 per cent., as given in the paper. The author's power factor of 47 per cent. for a tramway load was abnormally high. He found 28 per cent. an outside figure. He would also question the accuracy of the £120 for the average cost per kilowatt of maximum demand, which he thought high. The average cost for plant installed was from £60 to £70 per kilowatt, and there was not a margin of 100 per cent. of spare plant. As regards the maximum demand system of charges, he did not think this would survive. With the extended use of electricity the importance of the diversity factor would not be so great, and he thought that flat rates for the various classes of consumers would be generally introduced instead. At Sunderland, where the price of gas was 1s. 5d. per 1,000, it was soon recognised that they must get other than lighting consumers on to the system if the undertaking was to extend. Their efforts to obtain large power consumers had been so successful that out of 11 shipyards and engine works within the area, eight were now being supplied, and two others had agreed to come on. They had sold 5,000,000 units last year, and expected to sell 7,000,000 next year. The consequent improvement in the power factor by the load from these large consumers had caused the coal consumption to drop from 8lb. to 9lb. per unit down to 4 8lb. At the present time the daily load factor was as high as 47 per cent., and they were able to reduce the lighting charges. He would point out the fact that the improvement in load factor caused by tramways was not permanent, as the tramway load did not increase in proportion to the lighting.

Bailie WILLOCK, of Glasgow, thought that, instead of abandoning the maximum demand system because the people could not understand it, they should educate the consumers to appreciate the system. The gas undertaking in Glasgow was extending its business on the same lines by offering special facilities to long-hour consumers. They had adopted a principle of favouring power consumers whose load did not overlap the lighting peak. With the exception of the hours from four to six during the three winter months supply for motors could be obtained at ¾d. per unit. He believed in having an active canvass made of the district in order to secure new consumers.

Mr. H. FARADAY PROCTOR complimented the author on the curves he had prepared to show the variation of costs with power factors. He asked for further information as to how these curves were obtained, so as to know if they were applicable to all undertakings. He agreed that the maximum demand system was not entirely satisfactory, as it regulated the charge to a consumer by his own demand irrespective of the total demand on the station, which really affected the cost of supply. As regards the intermittent supply in which the power could not be used during the lighting peak, he did not think this would find favour. In a factory the cost of power was small compared with the total cost, and it would not pay to shut down the factory during certain hours in order to save a small amount in the cost of power.

Mr. H. L. P. BOOT, of Tunbridge Wells, said that in spite of Mr. Snell's remarks they really charged on the maximum demand system in Sunderland, as they varied the cost of the unit according to the class of consumer and the number of hours he used the supply. He had found that the power factor of public lighting exceeded 20 per cent.

Councillor BUZZY, of Poplar, advocated the linking up of adjacent municipal electrical undertakings, so that current might be interchanged one with the other in the same way that the various water companies shared the demand for water when there was a likelihood of a water famine. He thought that this linking up of adjacent undertakings would improve the power factor, and enable the municipal undertakers to supply at lower rates. In view of the proposed competition from a big power company in London, this joint action should be promptly organised.

Councillor SINCLAIR, in reply, said that his paper was intended to be of the general character, and it was quite likely that Mr. Snell's figures were more accurate in detail. He did not think, however, that the average cost per kilowatt demanded of £120 was too high. He obtained this figure by dividing the total capital outlay for a large number of stations by the total maximum loads observed on the same. They did not want a flat rate, but rather a scale which varied the change with the load factor.

## Street-Lighting.

BY E E HOADLEY, CHIEF ELECTRICAL ENGINEER, MAIDSTONE.

The subject of street-lighting, although a well-worn one, and one about which several papers have previously been written, and read before this association, is, to the author's mind, a subject admitting of a great deal more discussion, and on which there is still a large amount of knowledge and experience to be gained, if anything like universally good and successful results are to be obtained. In this paper the author proposes to deal with the question from the point of view of a central-station engineer, and to confine himself more especially to those problems which occupy the attention of an engineer in a town of moderate size, say 50,000 people, leaving to others, more competent and with greater experience, the fight as to the best means of lighting the principal streets of the Metropolis and our other great towns. It is the hope of the author that these remarks will promote a healthy discussion and be found of interest to at least some of the members, and if the result is that a larger number of the streets in those towns having an electricity supply are in the future so lighted, this paper will not have been written in vain.

The three chief points to be borne in mind by an engineer who is trying to get this street-lighting business into his own hands are as follows: (1) that the light given shall be superior, or at least equal, to the existing lighting in the streets; (2) that the cost to the ratepayers shall be very little, if anything, in excess of that already paid; (3) that the business shall be done at a profit to the electricity works. To attain these three conditions simultaneously is by no means an easy matter in towns where, as in Maidstone, gas is exceedingly cheap and the gas company is pushful and enterprising; however, the problem is by no means insoluble.

Up till a few years ago, leaving the arc-lighted streets out of the question, it was a fight between the flat-flame gas-burner and the carbon-filament electric lamp, a fight in which the honours were pretty evenly divided, and provided suitable fittings and methods of deflection were used, the electric lamps had, if anything, the better of it. At this stage the incandescent gas mantle made its appearance, and having got over the troubles of infancy and grown strong enough to withstand the vibration caused by the street traffic and winds, became at once a serious and successful competitor of the carbon-filament electric lamp, and for some time bid fair to monopolise what is commonly known as side-street lighting. A good many men will differ from the author on this point, but a special study of side-street lighting and an experience extending over seven years has convinced him that he has failed to show the average man in the street that as good a light can be obtained from the carbon-filament lamp for the same price as from an incandescent gas mantle, and this in spite of all that illumination photometers will tell him. At this period of the fight the Nernst lamp made its appearance, and, after many initial trials and partial failures, has survived, and, while still imperfect, is, the author hopes to be able to show, able to compete successfully with the incandescent gas mantle for the lighting of our less important thoroughfares. Maidstone was, the author believes, practically the pioneer of street-lighting with Nernst lamps, and a good deal of trouble was taken in experimenting with the various types of lamps and fittings before anything like a standard was arrived at. As most of you know, the Nernst lamp, which is simply the principle of the gas mantle applied to electric lighting, is made up in several forms. Firstly, the lamp known as the "A" type, which is the one most generally used; this lamp has a vertical glower, or light-giving filament, and is made to take either half or one ampere at pressures varying from 100 to 250 volts. This half-ampere lamp at 230 volts, giving about 75 c.p., has so far proved by far the most satisfactory in use in Maidstone. Secondly, the "B" type lamp, which is a smaller form and fitting into an ordinary lamp-holder, and having a horizontal glower; this was the type the author originally hoped to use, as a lamp taking only quarter

Digitized by Google

of an ampere at 230 volts will give from 32 c.p. to 35 c.p., and seemed to be just the lamp required at the time; this, however, had to be given up for reasons set out hereafter. Then we come to the rather newer forms of the Nernst lamp, the "C" type or "Luna" lamp, having a horizontal glower fixed close up to a white porcelain backplate; and, last of all, the "D" type, which is a "B" type lamp enlarged and improved and giving about 75 c.p. with an energy consumption of about 110 watts.

Experiments in street-lighting and tests have been made in Maldstone with examples of all these various types of lamps, with the following results: The tests were made to determine, firstly, the average life of the burners; secondly, the effect on the life of variation in voltage and of vibration; and so far as the results of these tests prove, both with the "A" and "B" types, very little difference in the life was observed either with a voltage rise of nearly 4 per cent. or in lamps exposed to a considerable amount of vibration. The first test consisted in taking batches of six "B" type Nernst lamps, the first six having a 210-volt burner and a 20-volt resistance, the second six having a 215-volt burner and a 20-volt resistance, and the third six having a 220-volt burner and a 20-volt resistance. These were all connected up on a nominal 230-volt circuit and switched on; they were then switched off once each day and allowed to get cold and then switched on again, so as to approximate as closely as possible to the usual working conditions. The following results were then obtained:

*230-Volt Lamps.*

1. Failed at 555 hours.
2. Failed at 1,494 hours.
3, 4, 5, and 6. Still burning at the end of 1,800 hours.

Average burning life, 1,543 hours. Assuming the burners to be useless at 1,800 hours.

*235-Volt Lamps.*

1. Failed at 1,675 hours.
2. Failed at 598 hours.
3, 4, 5, and 6. Still burning at the end of 1,800 hours.

Average burning hours, 1,580 hours.

*240-Volt Lamps.*

1. Still burning at end of 1,800 hours.
2. Failed at 707 hours.
3. Failed at 824 hours.
4. Still burning at the end of 1,800 hours.
5. Failed at 476 hours.
6. Failed at 411 hours.

Average life, 1,004 hours.

The lamps have been taken as burnt out at the end of 1,800 hours, as although the lamps were still intact, the candle-power had very considerably decreased. In the second test, 12 "B" type lamps, having a 220-volt burner and a 20-volt resistance, were taken, and six of them suspended from a fixed board and six rigidly mounted on a board, which was exposed to a constant periodic vibration and at intervals to jars of a harder nature. The actual figures of this test are not available at the present time, but the general results were quite as good from those lamps exposed to the vibration as from the fixed ones. The third test consisted in putting some of the "B" type lamps up in the streets, and measuring the illumination at various distances from the post with a "Trotter" illumination photometer. The average results obtained with a well-designed reflector were as follows:

| 10ft. | 15ft. | 20ft. | 30ft. | 40ft. |
|---|---|---|---|---|
| 0·048 c.p.f. | ·03 c.p.f. | ·017 c.p.f. | ·008 c.p.f. | ·004 c.p.f. |

On the above results a great many of these quarter-ampere "B" type lamps were put up in Maldstone, and for a short time the results were satisfactory, the general illumination competing very fairly with that obtained from a single gas mantle in average condition. After a short time, however, it was found that the candle-power of these small lamps fell away very considerably in some cases, and in others hardly at all, with the result that as soon as the burner began to deteriorate it could not hold its own with the gas mantle, and people began to grumble. These lamps have now all been replaced by the half-ampere "A" type lamps.

Similar tests to those carried out on the small lamps were made on batches of the half-ampere ones, and the general results went to prove that the burners were very little affected by ordinary vibration likely to be met with in the streets, certainly not enough to justify the author in putting in spring suspensions for the lamps; but in the case of the half-ampere lamps it was found that better results were obtained by using a 220-volt burner and a 20-volt resistance on a 230-volt circuit, and this result has been confirmed by several engineers in other towns who have been large users of these lamps, and also by the manufacturers themselves.

The author has some 350 posts at the present time, most of them having a half-ampere lamp rigidly fixed and suspended from a swan-neck at the top of the existing gas column, the burner being about 11ft. from the ground, each lamp being housed in by the upper part of a special reflector which is used to get a better distribution of the light; clear glass globes are used, the general public preferring brilliancy to good distribution, although a good many prism globes were used at first. There are also some 30 posts fitted with the new "D" type lamp, but these have been in use for so short a time that the author cannot speak with any certainty as to their performance.

The "A" type lamp, however, has been in use at Maidstone for about three years, and during this time the life of each individual burner has been kept very accurately, and from the results obtained from a good many hundreds, it is found that the average life is 676 hours, and this has somewhat improved lately. Very few resistances fail, but there has been at various times a good deal of trouble with the cut-out coils in the lamps burning out. This was pointed out to the makers, and evidently more attention has been given to this point, as lately very little trouble in this direction has been experienced. It is the author's general experience that wet weather exercises a deleterious effect on the burners, which have to be replaced much oftener during a spell of wet weather than during an equal period of fine weather. The author would like to hear whether this has been found to be the case elsewhere, and whether anyone can offer a reliable explanation. The average illumination results obtained from a half-ampere "A" type burner with a well-designed reflector are as follows:

| 10ft. | 15ft. | 20ft. | 30ft. | 40ft. |
|---|---|---|---|---|
| ·14 c.p.f. | ·06 c.p.f. | ·03 c.p.f. | ·014 c.p.f. | ·007 c.p.f. |

and these figures compare very favourably with many results taken by the author from a single gas mantle in good average condition throughout the town.

Experiments were also made with the "Luna" type of lamp, but owing to the position of the burner the distribution of light is not, in the author's opinion, at all satisfactory or suitable for street-lighting; no arrangement of reflectors that he has up to the present been able to devise has got over the fact that the larger proportion of the light is thrown vertically downwards.

To sum up the author's experience with Nernst lamps in a few words, the greatest fault he has to find with them is their want of uniformity. This is most apparent in the life of the burners, as, although the average life obtained in Maldstone is 676 hours, yet they have had many burners in use for over 1,000 hours, and several between 2,000 and 3,000, equally they have had many which have failed before they have reached 100 hours burning. This want of uniformity is also noticeable in the way in which the candle-power falls off; some burners do not appreciably drop for quite a long life, while others lose a great deal of their light-giving properties in a very short time, and will then last in this condition for a long while.

These remarks finish all the author has to say on Nernst lamps themselves, and he would like to now consider the three problems which confront the station engineer before he can get the street-lighting into his own hands. Firstly, to give a light at least equal to that given by the ordinary gas mantle. A half-ampere "A" type lamp at 230 volts will give a degree of illumination superior to that given by a gas mantle, both when measured by an illumination photometer in the streets and, what is far more important, when judged by the eye of the general public. This point having been settled, there remains the two more important ones—namely, that the cost shall not be greatly in excess of the cost of gas lighting, and that the electricity supply works shall get a profit out of the business. Firstly, as to the cost of lighting. As a result of a great many enquiries the author finds that the annual cost per post for a gas lamp having a single mantle varies from £3 to £4 as a general rule, which price is inclusive of trimming and maintenance charges; he thinks £3. 10s. per annum an average figure. These gas lamps are generally placed at distances apart varying from 40 yards to 50 yards, thus the cost of lighting a mile of street will vary from £122. 10s. to £154 accordingly. An equally illuminated street can be got by means of half-ampere Nernst lamps placed at a distance of 55 yards, although in Maidstone, as the existing gas columns are used, they average 50 yards, and the author hopes to be able to show that a half-ampere lamp can be kept alight from dusk till dawn for £3. 10s. per annum. The lamp having a 220-volt burner and a 20-volt resistance on a 230-volt circuit requires 390 Board of Trade units during the year, and has actually cost 9s. for renewals of burners, resistances, etc., 10s. for lighting and extinguishing and cleaning; interest and sinking fund charges calculated at 6 per cent. on £6 absorb 7s. 6d., repairs and maintenance of fuses, etc., have actually cost 2s. 6d. per annum, thus leaving £2. 1s. for the 390 units of electricity consumed, or 1·3d. per unit.

Before proceeding further it may be of interest to explain how the lamps are looked after and the details of converting a gas-lighted post to a Nernst lamp. Maidstone has about 350 posts to be maintained, spread over practically the whole of the town, and each post is supplied from the ordinary distributing mains, and has its own switch. There is a staff of four lads who do the whole of the repairs and renewals of burners, etc., clean-

Digitized by Google

ing, lighting, and extinguishing; one lad acts as a sort of foreman, and his duties consist in lighting up one round of about 60 lamps each evening, and during the daytime seeing to all the necessary repairs and renewals. Two other lads switch on a round each, and take alternate weeks in being on scout duty during the evenings for the renewal of burners that fail after lighting-up time, and assisting in the daytime in the same work; these two also switch one-third each of the total number of lamps in the morning. The fourth lad switches on a round in the evening, thoroughly cleans 30 lamps, globes, and reflectors each day, and switches off one-third of the lamps in the morning. A few of the lamps round about the station are switched on by a joiner's mate, and are not included in the above. The lads walk for the rounds in the town and cycle over the longer ones. The switching on is done in from 50 to 55 minutes, and the switching off in just over the hour, which are the times specified by the Highways Committee. As stated above, the average cost of attendance comes out at 10s. per post per annum, and for this sum they are kept in first-class order.

Now, as to the exact method and cost of conversion of each post: As it was necessary to keep the capital cost down as low as possible, special permission was obtained from the Board of Trade for the use of a very small cable for the lamp service; after the gas supply is cut off a service is run in from the nearest distributing main, using a special small service box and a twin armoured cable of ·0042 cross-section, which cable is run right up to the top of the post without any joints whatever, where the ends are clamped to the terminals of the switchbox, which is an integral part of the swan-neck fitting. This latter is wired from the switch terminals to the lampholder with twin rubber-insulated lead-covered wire of No. 3/22 size. The top of the lampholder and both openings of the switchbox are then filled in solid with box compound, and this has resulted in a very great reduction in the number of faults other than those due to the Nernst lamp itself. The actual cost of conversion of a lamp, including the post purchased from the gas company for £1. 10s., the swan-neck and fitting £1. 19s., the Nernst lamp, globe, wiring, cable, excavation, making good, is about £6. These lamps, when converted and painted, and with a special fitting and reflector made to the author's own design, look exceedingly well in the streets.

Having shown that the light given by a half-ampere lamp is somewhat superior to that given by the ordinary single-mantle gas lamp using gas under the ordinary pressure, and that the cost to the ratepayers per post need not be more than that already paid for gaslighting, at which price energy is to be supplied at 1·3d. per unit, it remains for the author to give his reasons for stating that at this low price energy can be supplied at a small profit to the electricity department giving the supply. The author looks at the matter from the point of view that this street-lighting business is a very desirable one to obtain, for, first of all, it is a load that is absolutely constant for 10 hours out of the 24 averaged throughout the whole year; this means a 40 per cent. load factor on a perfectly steady load, which is a thing that is not picked up every day. Beyond this there is the fact that street-lighting, provided it is well done, is a good advertisement, and will lead to mains being laid in a great many streets where otherwise they would not be laid, at least until some time later. Having acknowledged these two facts, the question is whether by taking on this street-lighting at 1·3d. per unit we should gain or lose money. The author's calculations and experiments were made on a basis of 350 half-ampere lamps, or exactly 37 kw.; now the extra expense to the electricity works is made up of interest and sinking fund charges on the value of the 37 kw. of our undertaking, which in the case of Maidstone means £147. 12s. per annum, and the extra cost of generating the extra 135,050 units required per annum for these lamps.

Before deciding the matter the author made some very careful experiments, lasting over six weeks, to determine what was the actual cost of generating these extra units, bearing in mind the fact that stand-by and up-keep losses must occur whether they supplied the street-lighting or not; thus the author contends that for this purpose it is only necessary to take into consideration the cost of coal, oil, waste, stores, etc., and repairs. From his experiments this totalled up to ·6d. per unit generated, or allowing a 20 per cent. loss between the switchboard and the lamps it amounts to ·75d. per unit; this with the capital charges makes up 1d. per unit, leaving a profit even after allowing for office expenses, etc., which are exceedingly small as there is only one account to be made out and no trouble at all in collecting it. The author is aware that in looking at the matter from this point of view he will be considered wrong by a great many people, but he cannot help thinking that this street-lighting business is of such a nature as to warrant it being considered from this standpoint, and it is, in his opinion, worth while looking at it from the point of view that "Shall we, as the supply authority, actually gain or lose money by taking it on."

In conclusion, the author would like to say a word or two about the future of side-street lighting. With the Nernst lamp, the mercury vapour lamp, the osmium lamp, and, later still, the tantalum lamp, he has no fear but that central-station engineers will be able to keep the business in their own hands. It behoves them all in these days of strenuous competition to do all that they possibly can to promote economy at both ends of the line—that is, in the cost of the production of energy and the efficiency of the light-giver—by giving careful thought and trials to these new appliances as they come along, and not always waiting for the results of someone else's experiments. The introduction of these newer lamps seems to the author to be of the highest importance, as it means the same amount of light as with the carbon-filament lamps for less than half the same expenditure of energy, and it is at this end of the line, he feels sure, that the greatest advances will be made, advances which will have much more effect on the final result than at the power station end, as he would be a bold prophet who would state that within the next few years a reduction of 50 per cent. will be made in the cost of production of the unit. Personally, the author considers the Nernst lamp, although still far from perfect, to have been the saviour of the side-street lighting business for the electrical world. The chief improvements he would suggest in its manufacture are: that the burner should be made a more mechanical job, and that the actual filament when broken should be capable of easy replacement by the user at a cost of a few pence, instead of, as at the present time, the whole burner, including the heating coil and its support and connections, being thrown away, at a cost of nearly 2s. So far as his experience with the "D" type lamp goes, the author is inclined to think that this will be the most useful type for street-lighting, as up to the present, beyond burners going, he has not had a single failure due to resistance or cut-out troubles or from bad insulation in the lamp, and it is much more easily dismantled and put together than the larger and earlier "A" type, and is only half the price. The author cannot say anything about the other new lamps, as he has not yet been able to test them under street-lighting conditions. The mercury vapour lamp seems to have the germs of a very useful article in it, but, so far, the lamp he has had has not got out of the test-room. The ideal lamp for the lighting of the less important streets will, I think, be found eventually in a small-flame arc lamp taking about 100 watts, and having a magazine feed so that it will burn some 50 or more hours without attention. The manufacturers who first produce a reliable lamp of this description, or something of equal efficiency, will reap a rich harvest.

The author hopes that these few remarks he has been enabled to put before the association will lead to a good and profitable discussion, as there are many points on which he and others are anxious to gain information.

Mr. G. WILKINSON, of Harrogate, opened the discussion on Mr. Hoadley's paper, and said that the subject was a most interesting one to all at the present time. He was pleased to note that at Maidstone one-half of the lamps in the streets were electric. He thought that the success of the Nernst lamp was handicapped by the fact that their manufacture was a monopoly, and that the German firm who made them would not listen to the demand of engineers for improved details. He asked if Mr. Hoadley had included in his figures for the average light of Nernst lamps those which lasted 2,000 hours and over. He had found that after 1,000 hours the light given had fallen so low that the lamp should not be used. His average life for Nernst lamps was 580 hours. He thought it was a mistake to have an individual connection from the low-pressure main to each street lamp, as 80 per cent. of the faults on the low-pressure side of one system he knew of were due to connections for street-lighting. He advocated instead a completely separate system of mains from the station for the supply of the street-lighting. The lamps could then be switched on or off from the station, which resulted in a considerable saving in labour and power. Thus in the three nights before and after a full moon he had found it possible to save 7½ per cent. of the total energy required for street-lighting by judicious switching on and off. As regards the use of small flame arc lamps, he had experimented with one taking three amperes which was not so efficient as the Nernst lamp; the figures he found were 1·8 watts per candle for the arc lamp as against 1·2 for the Nernst.

Councillor STEVENSON, of Edinburgh, said that they had been experimenting on side-street lighting with Nernst lamps in Edinburgh. He believed in supplying street-lighting at cost price, as it was not right that one corporation department should make a profit out of another. They had used two quarter-ampere Nernst lamps in the same

Digitized by Google

globe and switched one lamp off at midnight. Mr. Newington's estimate of cost for the supply of current to these lamps, their upkeep, and cleaning was £2. 0s. 5d. per year. The interest and sinking fund charges would be 4s. 8d., making a total cost of £2. 5s. 1d. The actual cost of installing the new lamps and lanterns on the top of the present pillars would be £1. 17s. 6d. each They were now supplying 1,000 10-ampere arc lamps at a cost of £10. 15s. per annum. They had given an offer recently to light 200 more of these arc lamps for £9. 10s. per annum, one half of the lamps being switched off at midnight. The competition of the gas undertaking was very keen, as they actually quoted 2s. per thousand for gas supply to incandescent lamps in the street, as against 2s 5d. for gas for the flat-flamed burner. He calculated that even then the electric light was able to hold its own.

Mr. T. P. WILMSHURST, of Derby, commented on the fact that the flame arc lamps were not long burning; thus, while they could get open-type lamps to burn 60 hours, 18 hours was the longest life he knew of for the carbons of a flame lamp. He also complained that these carbons were dear. He thought that the success of Mr. Hoadley was due to the good price he obtained of £3. 10s. per lamp in competition with the 4ft. incandescent gas lamp. In Derby the gas lamps were supplied for £1. 10s. per annum, which included everything except lighting and trimming. He thought the firm supplying the Nernst lamps were to blame for making extravagant claims as to what they would do. The lamps were badly made, and gave considerable trouble in various details. The heater was often placed so far away from the rod that the lamp would not light up. He had also noticed that as the life of the lamp increased, the time taken for the lamp to light after being switched on also increased. He did not agree with the use of spare plant for street-lighting.

Alderman S. SMITH, of Liverpool, was a strong advocate for gas lighting, and commented on the success of the gas lighting in Liverpool streets. He also questioned the estimate which Councillor Stevenson had given, as he had found considerable difference between estimates and performances.

Mr. HADYN T. HARRISON said they wanted one definite means of comparing street-lighting. Mr. Hoadley referred to two—*i.e.*, the man in the street and accurate measurements of candle-power. He thought they should stick to one or the other, as it was no good making accurate measurements of the light obtained if the judgment of the man in the street was afterwards to be taken. He noticed that the figures for candle-power feet from the gas lighting at Maidstone were not given in the paper, but he had seen them, and they were very favourable to the electric light. He deprecated the undue claims made for the candle-powers of rival illuminants. With incandescent gas burners he rarely found one-third of the candle-power stated. Electrical engineers were also to blame, as the 500-watt arc lamps would never give 2,000 c.p. in the street with the globes on. He recently had to test some large gas lamps supposed to give 800 c.p., and found that 300 c.p. was the light obtained. Again, a number of 40-c.p. Nernst lamps did not give more than 20 c.p.

Mr. S. E FEDDEN, of Sheffield, said they had no electric street-lighting in his town. He had tried the Nernst lamp of both the B and D type, and did not consider them a success. He thought people judged street-lighting by the glare in their eyes. Streets in Sheffield which seemed to be brilliantly lighted had a very poor light distribution, which did not enable print to be read in the middle of the road. He had recently tried to introduce flame lamps for street-lighting, but although they were cheaper than incandescent gas, light for light, they had not been successful. He had hopes that the tantalum lamp would help them in the competition, and he was using two of these lamps in series on the 220-volt circuits.

Alderman J. P. SMITH believed in the electricity department being actively managed by the engineer as a separate concern quite independent of the other undertakings of the municipality. It could be left for the committee or the council to check any undue competition between departments. He thought that the electric lighting of the Edinburgh streets would compare most favourably with the gas lighting at Liverpool, both as regards cost and the light obtained.

Mr. Hoadley reserved his reply, which will appear in due course in the *Transactions*.

During the afternoon visits were paid to the generating stations at Dewar-place and McDonald-road.

In the evening the Lord Provost, Magistrates, and Council of Edinburgh received the members and their ladies at the City Chambers.

## THE ELECTRICAL CONTRACTORS' ASSOCIATION.

The annual banquet of the Electrical Contractors' Association was duly held on Tuesday evening last at the Holborn Restaurant. As to the size of the gathering, it need but be said that the accommodation afforded by the King's Hall was almost fully taxed, thus indicating a flourishing state of the association. Mr. W. R. Rawlings presided.

The keynote of the after-dinner speeches was struck by Mr. E. L. BERRY, on whom it devolved to propose the toast of "The Councils and Municipalities." He gave credit for the many excellent services rendered by those bodies, praising, in particular, the sound work carried out in the provinces, but fell foul of their trading propensities, holding that municipal authorities had quite enough to do with legitimate undertakings without going out of their way to spoil contracting work. He referred to the case of Shoreditch, where failure had attended the attempts of the Council to establish a municipal wiring department.

Mr. G. L. GOMME (clerk of the London County Council), in reply, argued that extension of work by the municipalities was good for trade, and if trade were hurt in one direction there would be a corresponding development of industry in another. The work of the great authority which he served was not necessarily in conflict with trade interests. In Germany municipal work was supported by people in similar positions to which they held.

Mr. H. BUSBY BIRD (Mayor of Shoreditch), who also replied, frankly admitted that the electric wiring experiment referred to by Mr. Berry had been a practical failure. He had his own place wired by the department, and thanked the Lord he was alive to tell the tale. Now every facility was given to local contractors for the work, and the Council did not intend in future to meddle with wiring or fitting work, because they had had some.

The toast of "The Electrical Contractors' Association" was proposed by Mr. B. H. ROLFE, who pointed out the great benefit which had resulted to the trade as a whole from the activity of the association.

The PRESIDENT, in responding, said the funds of the association were used to promote the advancement of the electrical contractor, to protect him, and to bring about better trading between the contractor and manufacturers from whom he purchased goods. There were some men they did not admit into their association—for instance, the man who asked for a rule to measure megohms, and how many of the latter went to a foot; or the man who ran three wires to each point, because the installation was to be connected up to a three-wire system of distribution; or, again, the man who complained of the fuse wire which was always melting.

The "Casino Orchestra" performed during the banquet, and some excellent songs were interspersed with the speeches afterwards, while brilliance was imparted to the scene by orange rays from the "Excello" arc lamps, which have been substituted by the Union Electric Company, Limited, for arcs of older type previously in use. Nor was their radiance obscured by the tobacco fog which gathered.

## PERSONAL.

The Partick Town Council have increased the salary of Mr. J. Bryce, burgh engineer, from £450 to £500 per annum, and that of Mr. H. B. Maxwell, burgh electrical engineer, from £250 to £300 per annum.

Mr. Herbert Vickers, assistant tramways engineer to the Wolverhampton Corporation, was married last week to Miss Bertha Thornley, second daughter of the late Mr. James Thornley, of Bolton.

### RESPONSIBILITY AND REMUNERATION.

Summer meetings are in fashion. All classes of municipal officers have been hob-nobbing together, reading papers, passing opinions, visiting works, and generally getting rid of the high-pressure verbosity that has accumulated during the past twelve months. There is a topic simmering throughout the municipal world which to us seems wrongly considered. Agitation on all sides is being carried on for superannuation. In our view superannuation is a mistake, except in particular cases and under certain circumstances. What is required is a proper, perhaps a generous, salary for responsibility. A man should be paid, not partly paid, and should be trusted to make his own provision for old age. There is no shadow of a doubt from economical considerations that the paying of a pension means underpayment during years of work, and the using of the balance between what is and what ought to be paid as insurance premiums. While we are writing, municipal electrical engineers are in conference. They are meeting for the purposes above mentioned, and we take the opportunity of referring to their position as regards remuneration. On the whole, they are underpaid. It will be said that there exist a few prizes. That may be so, but does anyone doubt but if some of the men engaged in the work put the same brains and energy into business concerns the ultimate reward would be far and away superior to anything they are likely to get in the profession in which they are working. They are not likely as municipal electrical engineers to accumulate large fortunes—indeed, it is only the exceptionally placed among them who can contemplate with equanimity the expenditure necessary to keep them abreast of progress. Many are tempted to grow careless, to depend upon satirical and cynical notes or a lot of statistics for their information instead of reading and digesting the original papers. The curse of true knowledge is dependence upon a lot of abstracts good enough in their way, but which ought to be used for nothing more than an aid to memory. As we say, much of this casual glancing at the records of professional progress is due to inadequate pay. It is not the state of things calculated to ensure the best results. In these days of progress education should be continuous and thorough. New developments are of frequent occurrence in all branches of engineering, and unless the engineer entrusted with responsibility can keep abreast of the times it is unreasonable to expect he will be able to do the best for himself or for those who employ him. Every facility for acquiring the fuller knowledge should, therefore, be given him. It is in some quarters fashionable to scoff at the length and prosiness of German literature; while, on the other hand, we are continually dinned with the view that Germans and Americans are better equipped with knowledge and better trained in its use than their British competitors. Has it ever occurred to speakers and writers that many of the things they suggest are somewhat incompatible, and especially when we are told what we don't know and don't do. Might it not be possible that we do know and don't do just because we do know, and that the lack of action is due to the further knowledge that we can do better by following our own devices. Of course, it is impossible in this world to make responsibility and remuneration always exactly proportional. The responsibility of a man in charge of a small station with a moderate capital is often far greater in mental and bodily wear and tear than the responsibility of a man in charge of a large station with a commensurately large capital, yet the latter, in the natural order of things, gets the higher salary. The former partly lives on hope—hope

Digitized by Google

to get to the higher-paid position. The desire for a pension seems to indicate incapacity to provide for the future—but here is the fun of the fair. The man is pronounced capable of bearing a greater responsibility, so that the implied inability to undertake a responsibility affecting himself is ludicrous.

## THE VERBAND DEUTSCHER ELEKTROTECHNIKER.

### Thirteenth Annual Meeting—Dortmund and Essen.

[FROM OUR SPECIAL CORRESPONDENT]

(*Continued from page 877.*)

Reverting to the first day's business proceedings in Dortmund, brief reference may be made to the reports of the various committees. It appeared from the report of the Safety Rules Committee that they had entrusted a sub-committee with the revision of the regulations for mines, and another sub-committee with the drafting of revised rules for theatre installations.

With regard to the Committee on Hysteresis, it seemed that the question of testing had again occupied their principal attention, with the result that all three methods hitherto perfected—namely, those of Epstein, Möllinger, and Richter respectively—are to be allowed. But to facilitate checking the rated loss, it is to be stated with which of these methods the check test shall be made. Moreover, this loss is to be that which obtains when the E.M.F. curve of the testing current is sinusoidal. As regards ageing, the committee had defined its coefficient as the percentage increase of loss after 600 hours' heating to 100deg. For the rest, they had refrained from dealing experimentally with the question of ageing, since the Reichsanstalt had offered to make the necessary investigations, and, indeed, to undertake a systematic research into the whole question of relationship between the magnetic properties and chemical composition of iron. The committee therefore regarded their mission as fulfilled, and asked to be dissolved, a request which was acceded to by the meeting.

It may be mentioned here that the council of the Verband have voted £250 towards the cost of the proposed research by the Reichsanstalt, which it is estimated will occupy from four to five years to complete. The reports by the other committees were for the most part merely a forecast of recommendations which will be submitted in elaborated form to the next annual meeting of the Verband for final approval.

The first paper was read by Dr. Norden, and reintroduced the question of "standards for arc lamps," the importance of which is urged by the Vereinigung der Elektricitätswerke, from whom he had received his brief. In the course of his somewhat lengthy contribution Dr. Norden pointed out the increasing need in practice for accurate data relative to the candle-power of arc lamps. For interior lighting, so long as the arc lamp had to compete only with the electric glow lamp its superiority in regard to economy and illuminating power was unchallenged, but since the introduction of the Nernst lamp and other current-saving lamps, it paid to consider which would best meet the requirements of the particular case in view. The same applied to outside lighting. A street, dock, or railway station lighting installation had nowadays to submit to comparison with one or other of the many modern systems of gas-lighting, almost before completion Then the classification of arc lamps according to their respective suitabilities for given requirements must be considered. If manufacturers of arc lamps could agree among themselves to adopt a uniform terminal voltage and size of carbon in regard to lamps of similar types for each ampere capacity, it would then devolve upon carbon manufacturers to give the necessary guarantees of candle-power, since there would be no longer any difference in the details of construction which could affect the illuminating power of the lamps. Unfortunately, however, there was little prospect of such an agreement being arrived at, not only because of the difficulty of converting so many minds to one view, but also by reason of the increasing demands on the lamps due to progress in the art of lighting, which would entail a constant revision of such standards. But assuming the guarantees continued to be given by the lamp manufacturers as heretofore, it was no less desirable that these guarantees should be made as intelligible as possible, and that competing firms should adopt a common basis upon which to establish them. Both manufacturer and consumer would benefit thereby.

The author went on to show that the lack of uniformity in current practice made reliable comparisons of the data furnished by different firms almost impossible. It was desirable that all calculations as to candle-power, watts consumed per candle-power, etc., should be based on common standards, also that standard apparatus and

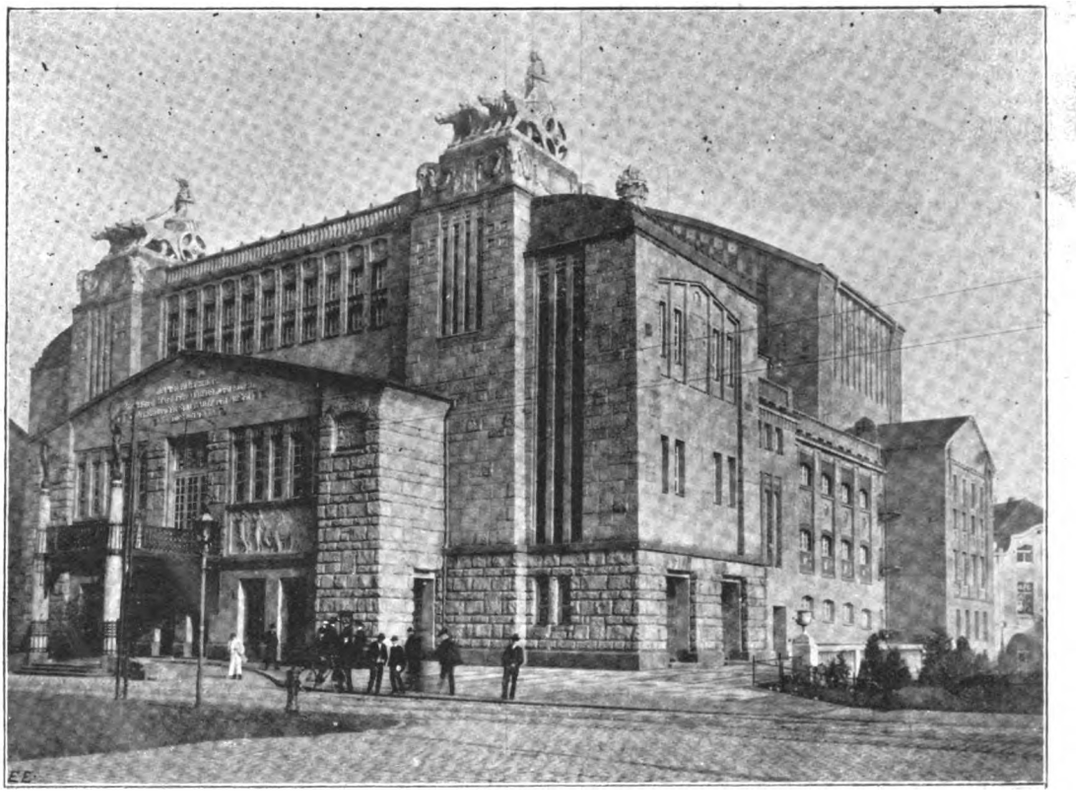

FIG. 2.—Stadttheater, Dortmund—Exterior View.

Digitized by Google

methods of measurement should be employed. True, the problem of photometrically comparing different coloured lights remained unsolved, but the increasing use of flame arcs had rendered the matter urgent, and it would be well to obtain the assistance of the Reichsanstalt in establishing a standard method.

In concluding his remarks the author expressed a doubt as to the attitude which manufacturers would adopt towards the suggested standards, although it was clear they would serve to suppress a competition which was opposed alike to the true interests of the trade and consumers.

The outcome of this paper and the subsequent discussion thereon was the appointment by the meeting of a committee to deal with the question of standardising the candle-power of electric lamps generally. This committee will be assisted by the Vereinigung der Elektricitätswerke so far as arc lamps are concerned.

The accompanying illustrations (Figs. 2, 3, and 4) are from photographs of the Dortmund Stadttheater, wherein a special performance was given for the benefit of the Verband on the second evening of their meeting. It will be seen that the theatre is a handsome one and quite new

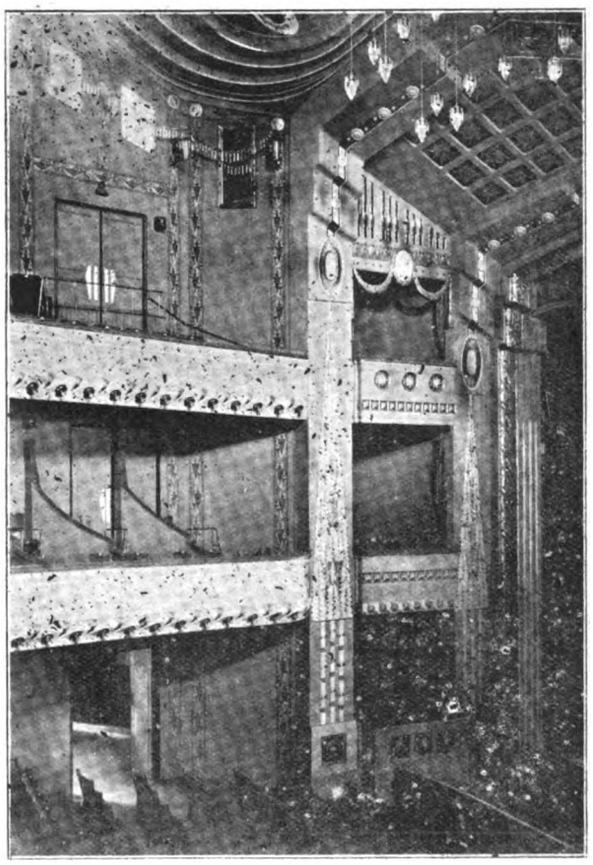

FIG. 3.—Stadttheater, Dortmund—Interior View, showing Pendant Lighting.

The single-lamp pendants (see Fig. 3) constitute an interesting feature of the lighting installation, being simple and quite in keeping with the new art style of general decoration. The entertainment provided was most enjoyable, and time was allowed between the two plays presented to hunt up old friends. It was during this interval that I heard of the honorary degree conferred upon friend Kapp, and had a chat about the latest thing in dynamos for train-lighting with Mr. Rosenberg, the inventor. This dynamo, it will be remembered, was fully described in the *Electrical Engineer* for April 28 last, pp. 600-602. It has attracted considerable attention throughout Germany—I might say the world—and arrangements have been made, I understood, for its manufacture in this country by Messrs. Mather and Platt, of Salford, Manchester. Among others, of whom their numerous English friends will be doubtless glad to hear, I also met Mr. Naglo, formerly with Messrs. Siemens Bros., at Woolwich, and the genial Heinrich who represents Weston instruments in Berlin. Notable absentees were Drs. Slaby and Aron, Prof. Georges, and Mr. Julius H. West, their places being filled by lesser lights.

*(To be continued.)*

## TRIPLE-EXPANSION ENGINE FOR MELBOURNE CORPORATION.

It is a matter of special interest to us to have to record the exportation of a large electrical plant to one of our colonies. The plant in question consists of a large 1,160-i.h.p. triple-expansion engine to run at 275 revolutions per minute, built by Messrs. W. H. Allen, Son, and Co., Limited, of Queen's Engineering Works, Bedford, coupled direct to a 750-kw. continuous-current dynamo built by Messrs. Crompton and Co., Limited, of Arc Works, Chelmsford. This set (of which we give an illustration) has been built to the order of the Corporation of Melbourne, Victoria, to form the main part of the generating equipment of their lighting installation.

The engine is of Messrs. Allen's standard three-cylinder, double-acting, triple-expansion, vertical enclosed type, the cylinders driving three cranks, set at angles of 120deg. It has been designed throughout with a view to obtaining

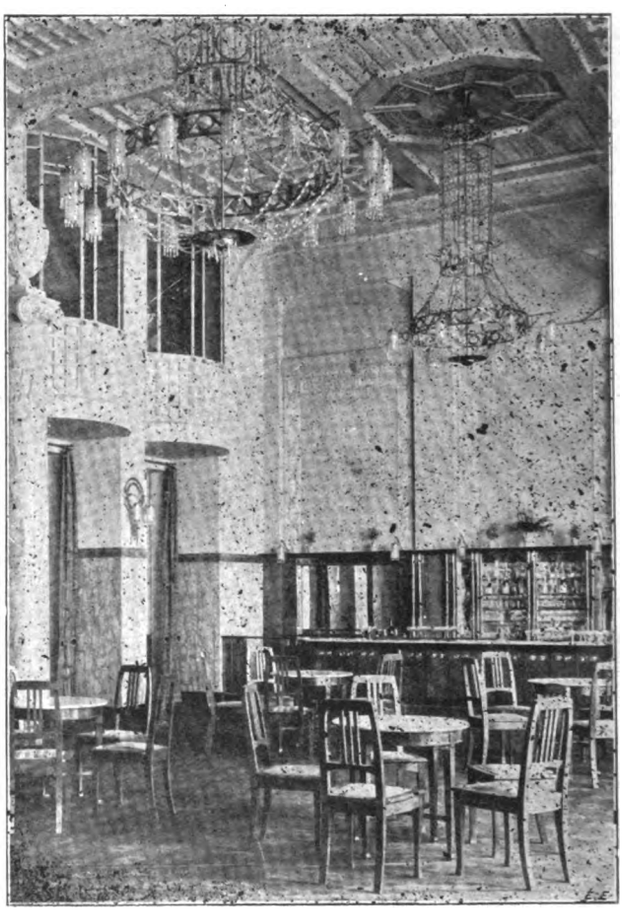

FIG. 4.—Stadttheater, Dortmund—another Interior View.

economical results over widely varying conditions of load when working with steam at 160lb. per square inch at the stop-valve with 150deg of superheat, and exhausting either into the atmosphere or into a condenser, capable of maintaining a maximum absolute pressure of 4in. of mercury; the full load when running non-condensing to be maintained by automatically by-passing high-pressure steam to the intermediate cylinder. The dimensions of the cylinders and the successive points of cut-off are so arranged as to produce as nearly as possible an equal distribution of power between the three cylinders, thereby ensuring an exceedingly even turning moment throughout the revolution of the engine. The weights of the reciprocating parts on each crank are also equalised in order to produce a good balance. With a view to still further reducing the vibration when running, cast-iron balance weights have been securely fixed to each of the cranks and arranged at such an angle with the crank as to reduce as far as possible the unbalanced couples due to the inertia of the valve gear, as well as those of the main reciprocating parts. The success of this system of balancing was a noticeable fact during the trials, the vibration being prac-

Digitized by Google

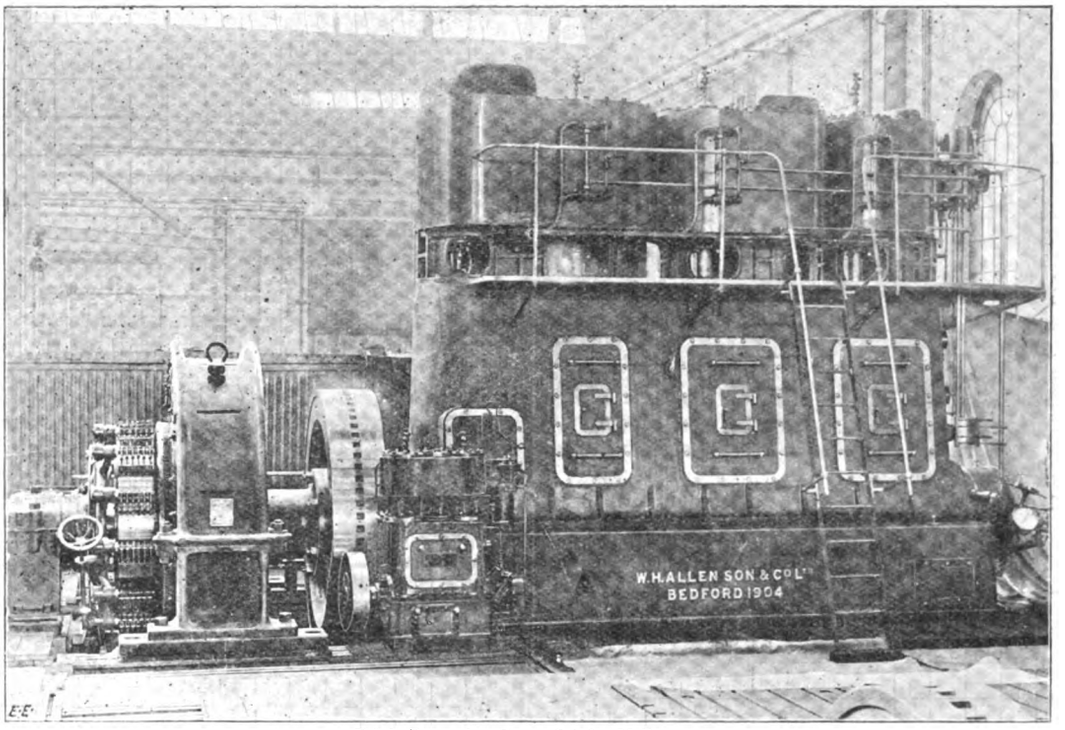
tically eliminated. The three cylinders are respectively 18in., 27in., and 44in. diameter, and have a stroke of 16in., and are made of a special mixture of hard, close, and tough-grained cast iron having a tensile strength of from 12 to 15 tons per square inch. They are also provided with the usual accessories in the way of drains and relief valves and provision for indicating. The intermediate and low-pressure pistons are of cast steel, and are fitted with Rowan's packing rings, and the high pressure piston is of cast iron of the solid block type, and is fitted with a solid packing ring of rectangular section, all three pistons being of equal weight for balancing purposes. The valves are all of the solid piston type, and take steam on the inside edges, thereby diminishing the pressure on the glands as compared with valves having steam on the outer edges.

The whole of the working parts of the engine are enclosed in a neatly designed and substantial cast-iron trunk, the walls of which carry the slides for the main cross-heads. Easy access to the interior of the trunk is provided for by three large doors arranged along the front of the engine, each door being furnished with a smaller hinged panel in its centre which permits of inspection of the working parts. The back of the trunk of the engine is also provided with smaller removable panels in order to facilitate inspection and adjustment of the main bearings. Each cylinder is cast in one with a flanged distance piece, by means of which it is securely bolted to the top of the trunk which has just been described, the cylinders being completely isolated from each other, this design having been adopted by the makers for all their standard types of engines, excepting the smaller two-cylinder types, as it ensures that there shall be no distortion of the frame of the engine under any conditions of varying temperature, with the result that the working parts are always correctly in line, and work freely. The whole of the trunk and cylinders complete are mounted upon a massive cast-iron bed-plate, which forms a reservoir into which the oil drains and from which the oil is supplied at a pressure of about 15lb. per square inch to all the working parts by means of a small valveless force pump driven from one of the eccentrics of the engine.

The crankshaft, piston rods, valve rods, connecting rods, and eccentric rods are all of Siemens-Martin open-hearth steel having an ultimate tensile strength of 28 to 32 tons per square inch, and giving under test an elongation of 28 per cent. in a length of 2in. The eccentrics are all of solid forged steel, the high-pressure valve eccentric being securely keyed on to the shaft, the remaining two eccentrics being forged solid in one piece with the shaft. The apertures through which the piston and valve rods enter the engine trunk are fitted with a bush of special construction without packing of any kind, which effectually prevents water from the cylinders from entering the crank chamber, and oil from the crank chamber from passing upwards to the cylinders. The main stuffing boxes are all fitted with metallic packings, that on the high-pressure rods being of the Spherical Metallic Packing Company's manufacture, and that on the intermediate and low-pressure rods being of a special fibrous material of Messrs. Allen's own manufacture. The whole of the bearings throughout, with the exception of the cross-head bearings, which are of gun-metal, are lined with white metal, and receive oil under pressure from the force pump described above.

The governor is of the company's standard crankshaft type, and can be regulated by hand whilst the engine is running to give a speed variation of at least 5 per cent. above and below the normal, and operates a compound double-beat throttle valve of special design placed between the main stop-valve and the engine, and so arranged that at overload steam is by-passed direct to the intermediate-pressure cylinder. On trial the governor showed a maximum momentary speed variation of 4·4 per cent., the steady variation from no load to full load being 2½ per cent. The flywheel is of the solid disc pattern, and is forced on to the end of the crankshaft and securely keyed. The dynamo side of the flywheel is accurately faced up to form the coupling for the armature. The cylinders, steam stop-valve, governor valve, and steam separator are all properly lagged with asbestos non-conducting composition, and are neatly covered with blue planished sheet steel, the whole presenting an exceedingly neat appearance.

All the hand levers, including those of the main stop-valve, drain cocks, by-pass valve, and speed regulation, are all operated from the floor level at the high-pressure end of the engine. In close proximity to these are the sight-feed oil impermeator, tachometer, and pressure gauges—an exceedingly convenient arrangement which permits of the entire regulation of the engine from one point.



Triple-Expansion Steam Set for Melbourne.

## THE ALTERNATING-CURRENT SERIES MOTOR.*

BY F. CREEDY, STUDENT.

*(Concluded from page 881.)*

The results of the three last-mentioned tests are shown in Figs. 20, 21, 22, 23, and 24.

In Fig. 21, Curve I. represents output plotted against

* Paper read before the Institution of Electrical Engineers.

Digitized by Google

speed (here the output includes friction losses). In Curve II. the iron losses due to rotation have been added. In Curve III. the field losses proper have been added also. Curve IV. includes the losses in the coil short-circuited under the brush. Curve V. includes the $I^2R$ losses in the armature. Curve VI. includes the compensating coil losses. Curve VII. represents the input.

In Figs. 22 and 23 the losses are added to the output in the same order, except that Curve III. represents the field losses, *including* those in the coils short-circuited under the brush. Thus the curves are numbered differently, there being only six curves instead of seven. In Fig. 22 it may be seen that the $I^2R$ loss in the armature is the greatest (the motor being perhaps overloaded). This amounts at the working speed (2,000 revolutions per minute) to about 15·5 per cent. The field losses are nearly as great,

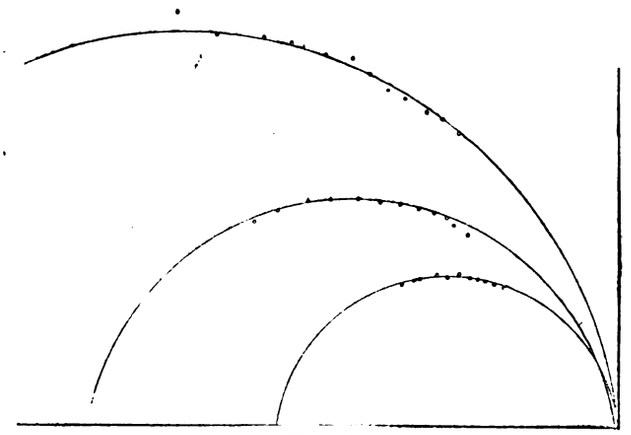


FIG. 20.

being 11·2 per cent. The losses in the compensating coil are 5·1 per cent., and the iron losses due to rotation 1·8 per cent. The losses in the coils short-circuited under the brush are quite insignificant. If we now turn to Fig. 23, giving the analysis of losses when we have 104 turns on the field, we see that the field losses are by far the largest, forming 17·9 per cent. of the input. The copper losses only form 7 1 per cent., the compensating coil losses 3 per cent., and the iron losses due to rotation 6 1 per cent. Fig. 22, giving the analysis of losses

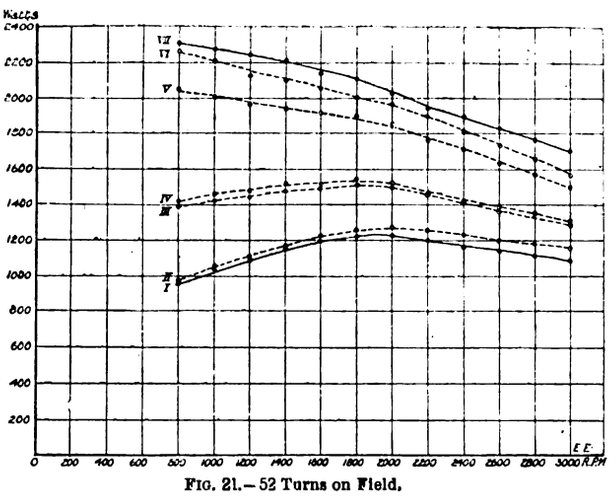

FIG. 21.—52 Turns on Field.

when we have 84 turns, forms an intermediate case. A comparison of these three figures is very instructive. It shows that the principal reason why the efficiency becomes constant at so low a value as 65 per cent., and cannot be raised by increasing the number of field turns, is because of the large iron losses. These are probably largely due to the fact that the machine has flat cast-iron end plates bolted direct on to the stampings, the field coils enclosing both stampings and end plates. This undesirable feature I was unable to alter. Fig. 21 in particular shows that the resistance of the machine is far too high. The resistance of the armature over the brushes is, in fact, 0 43 ohm. The other losses are not, I think, excessive, except perhaps the hysteresis due to rotation, which, in Fig. 22 especially, seems very high. In connection with this, it seems rather remarkable that in Fig. 21, when there were only 52 turns on the field, and consequently the flux was stronger than in the other two cases, the hysteresis, etc., due to rotation, is the smallest. It will also be noticed that the output + losses is considerably less than the input, and this suggests that the hysteresis due to rotation has been under-estimated. In Fig. 20 are given the three circles corresponding to the tests in Figs 21, 22, and 23. It should

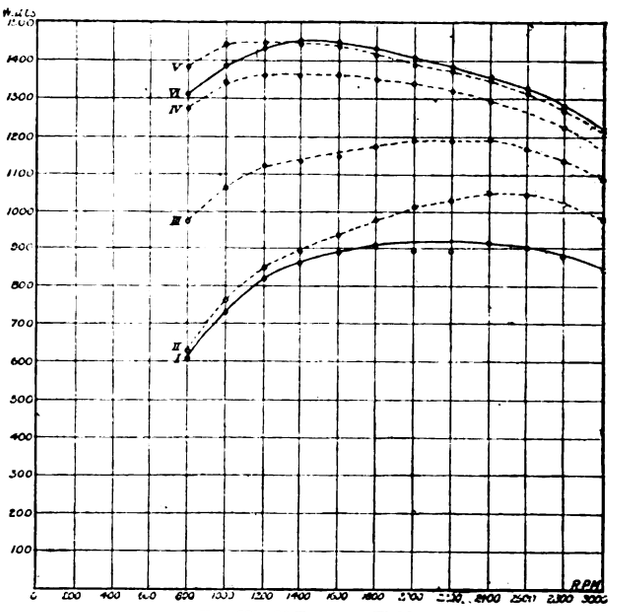

FIG. 22.—84 Turns on Field.

be mentioned, in this connection, that, since the compensating coil was put in, the centres of many of the circles observed have lain below the line of zero power factor. A possible explanation of this seems to be the following Unless the plane of the compensating coil is exactly perpendicular to the brush line (and this can only occur for one particular brush position), an E.M.F. will be produced by the rotation of the armature in the flue due to the compensating coil. This E.M.F. changes its direction as we move the brushes past the position of perpendicularity to the plane of the compensating coil. If it is in phase, instead

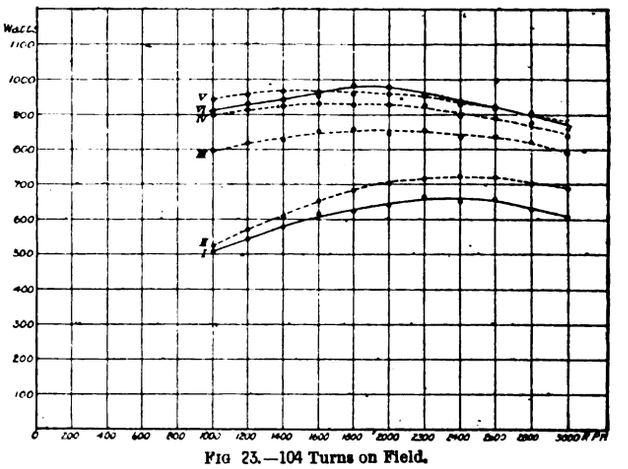

FIG 23.—104 Turns on Field.

of opposite in phase, to the current in the latter, it will tend to reduce the angle $\theta$ (Fig. 2), and may even make it negative, thus depressing the centre of the circle below the line of zero power factor.

In Fig. 24 are shown curves of output, power factor, and efficiency, plotted against speed. These were taken at 90 volts, 25 frequency, and with 52 turns on the field. They represent on the whole about the best performance of which the motor under test is capable. The output is excellent if we consider that the motor is about the size of an ordinary 1-h.p. direct-current machine. It weighs, in running condition, 169lb. At 100 volts the output would, of course, have been greater, certainly not less than 2 h.p. at 2,000 revolutions per minute. It was, however, found impossible

Digitized by Google

to keep the voltage of the generator up to 100 with the heavy currents taken. The power factor, too, is very fair, but the efficiency is decidedly low. At 2,000 revolutions per minute we have output = 1,230 watts; power factor = 0 83; efficiency = 59 per cent. If we compare this with the specification given above, we see that, allowing for the effect of the compensating coil, they agree very fairly. The output is very much greater, as one would expect, since it is proportional to the square of the current passing through the motor, the power factor is better, which is also what one would expect, and the efficiency is lower, which is accounted for by the compensating coil losses and the iron losses due to rotation, which were not taken into account in the calculations. Thus we may be fairly sure that a motor designed by the methods described above will

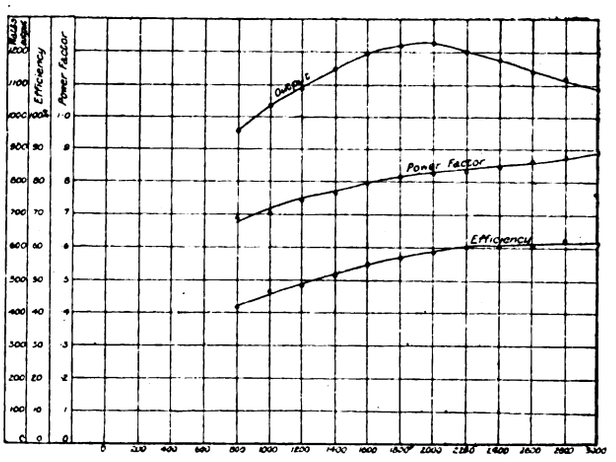

FIG. 24

fulfil its specification. The faults of the motor experimented on, and their remedy, are rendered quite clear by the above analyses of losses.

It is clear that in order to obtain a higher efficiency, a higher counter E.M.F.—that is, more turns on the armature—are needed. In order to decrease the armature $I^2R$ losses, a larger gauge wire is required. Thus the armature must be made considerably larger than in present direct-current practice. On account of the very small space occupied by the field winding a much more compact design

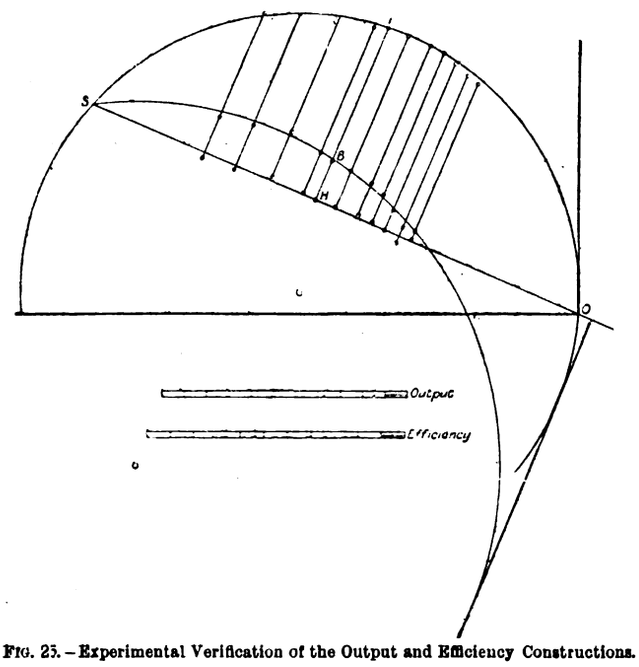

FIG. 25.—Experimental Verification of the Output and Efficiency Constructions.

of field magnet is possible, thus decreasing both the weight, the reluctance, and the iron losses. The iron, as mentioned above, should be distributed symmetrically about the axis of the main magnetic flux. A motor built in this manner would have good efficiency and high power factor, while the output per pound would probably be even higher than in the motor tested, which at full load gave nine watts per pound, 100 volts being applied. The reason why such good "weight efficiencies" are obtained with so small a motor is on account of the large number of armature turns employed. Though this method of design is adopted for quite other reasons, it is precisely the one recommended by Mr. Hobart in his book "Electric Motors," and elsewhere, as giving good "weight efficiency" in direct-current motors. In fact, when this experimental motor was tested with direct current, it gave about 3 h.p. at 1,400 revolutions per minute, with an efficiency of about 70 per cent, 100 volts being applied. The low efficiency is explained by the high $I^2R$ losses, as we have seen above. In this case we got 12·5 watts per pound, very nearly.

It has been shown experimentally above that in the alternating-current series motor the current moves on a circle as we vary the speed, and that the speed may be found by the construction given in Fig. 2. It is also clear that the torque is proportional to the square of the current. These two constructions being assumed, the constructions for output, efficiency, etc., follow mathematically, no further reference to the series motor being necessary. It was thought of interest, however, though not strictly necessary, to attempt a direct experimental verification of the two latter constructions, more especially as a verification of the efficiency construction would enable us to test whether the theoretical result that the efficiency is 100 per cent. at infinite speed, supplies us with a satisfactory efficiency scale. Fig. 25 gives us an experimental verification of the output and efficiency constructions given in Fig. 2.

A perpendicular I H was dropped from a point I on the current circle on to the standstill current, its length measured, the output corresponding to this point noted, and from these two observations the scale to which I H represents the output was found. Setting off the outputs corresponding to the other points on the current circle along lines through these points and perpendicular to O S, we get a series of points which, as Fig. 25 shows, lie very closely along O S, thereby verifying the output construction. The efficiency circle was next drawn, according to the rule given above, the length of I B and the (observed) efficiency corresponding to the point I noted, and from these the efficiency scale determined. Setting out the efficiencies corresponding to the other points on the current circle, from these points, in the same way as the outputs, a series of points is obtained, which, as may be seen, lie very closely along the efficiency circle. This verifies the efficiency construction. Comparing the efficiency scale as determined experimentally above with that deduced from the assumption that the efficiency is 100 per cent. at infinite speed, it was found, as had been suspected, that they did not agree, the latter scale giving efficiencies which were a good deal too high. Thus in practice it will be necessary to determine the efficiency scale experimentally.

Thus it will probably prove impossible to obtain a satisfactory test on the series motor by means of one or two observations taken at standstill, as may be done in the case of the induction motor. A brake test will always be necessary. It may be pointed out here that the Hopkinson test is perfectly applicable to the series motor, the power required by such a motor being supplied by another, exactly similar, coupled to it and acting as a brake. The wattless current taken by the machine, however, cannot be so supplied, and thus the generator must supply both the losses and the wattless currents required by both machines.

Throughout the series of experiments described above it has been found impossible to obtain satisfactory experimental values of the standstill current, on account of the fact that the contact resistance of the brushes is much higher at standstill than when running. This effect will probably occur in all commutator motors, though it may be less marked in large machines. It produces a slight decrease of the current and a considerable increase in its power factor on account of the enormous commutator losses. It was frequently found that the power factor of the motor when running at a slow speed, say 80 revolutions per minute, was *lower* than that at standstill, on account of the above effect. It was found impossible to keep the motor stationary for long with current flowing through it, as the brushes rapidly got red-hot.

I have usually been obliged to deduce the standstill

Digitized by Google

current from the observations of current, etc., when the motor was running, by means of the speed construction. In verifying the speed construction itself, the following method was adopted: According to theory, as may easily be seen, if O S (Fig. 2) does not correspond to zero speed, but to some other speed, say $a$ revolutions per minute, then S P will be proportional, not to the actual speed, $s$, but to $s-a$. Thus, if we plot S P against the measured speed, we ought to obtain a straight line, whatever the position of O S. This was found to be the case, and this fact forms the real verification of the speed construction. For one, and only one, position of O S, the curve between S P and the measured speed was found to pass through the origin. This was taken as the correct position, and is used in the curves given in Fig. 7 above.

In conclusion, my thanks are due to Messrs. Nightingale, Chaffer, Nealor, Hodgkinson, King, and Herbert for their assistance in the experiments described in this appendix. I have also to thank Mr. Nightingale for his assistance in preparing some of the figures.

## JUNIOR INSTITUTION OF ENGINEERS.

On Tuesday a reception was held at the Royal United Service Institution, Whitehall, in celebration of the institution's "coming of age." The president (W. H. Lindley, M.I.C.E., F.G.S.) and the chairman (Samuel Cutler, Jun.M.I.Mech.E.) received the guests at the top of the main staircase, after which the secretary (Mr. Walter Dunn) was presented with a magnificent silver loving cup. The ceremony took place in the theatre of the institution, and the president, supported by Messrs. Cutler, Tennant, Marshall, and Taylor, referred in the highest terms of eulogy to the eminent services rendered to the institution by Mr. Dunn, and also by Mrs. Dunn, during the whole of its existence. In the museum opportunity was afforded to inspect the Nelson Centenary Exhibition, as well as the permanent collection of models, specimens, etc., relating to the navy, army, and auxiliary forces. An excellent programme of music was discoursed by the band of the 21st (Empress of India's) Lancers (by permission of Lieut.-Colonel J. Fowle and officers), under the conductorship of Mr. Edmund Hinton; and vocal selections, which were much appreciated, were rendered by Miss Carrie Tubb, Miss Ada Gaskill, Mr. Frederick W. Lake, and Mr. Edwin Evans, Mr. Richard Cooper, A.R.C.O., being the accompanist. Several models and a collection of photographs, etc., kindly lent by the president in illustration of his address on municipal engineering on the Continent, delivered at the commencement of the session, were also exhibited. During the course of the evening lecturettes were delivered in the theatre on "The Invention and Manufacture of Steel Pens," by James P. Maginnis, Esq., A.M.I.C.E., and on "Britain's First Line of Defence," by W. J. Harding, Esq., M.I.C.E. The latter was illustrated by slides lent by A. F. Yarrow, Esq., M.I.C.E.

## FORTHCOMING EVENTS.

**Junior Institution of Engineers**—Summer meeting commences June 30. For particulars see issue of June 16.

**Incorporated Municipal Electrical Association.**—Convention at Edinburgh. On July 1 a visit will be paid to the Aberdeen Electricity Works.

**Third International Electric Tramway and Railway Exhibition.**—Opening at the Agricultural Hall on July 3 by the Earl of Derby, at noon.

**Municipal Tramways Association.**—Conference at the Agricultural Hall on July 4, followed by a smoking concert at 8 p.m. On July 5 the conference will be continued, and at 8 p.m. there will be a conversazione. On July 6 there will be an excursion to Reading and Henley at 11 a.m.

**University of Liverpool.**—Opening of new electrotechnics laboratory by Sir J. Swan, July 8.

**Permanent-Way Institution.**—Summer convention begins on July 21, continuing till July 27, in the course of which a visit will be paid to Holland.

**University College, London, Union Society.**—Foundation oration, "The Academic Side of Technical Training," to be delivered by Dr. A. B. W. Kennedy on June 29, at 5.30 p.m.

**Commerce with Abyssinia.**—We hear from Messrs. W. P. Thompson and Co., patent agents, Liverpool, that the Abyssinian Government has agreed to allow the merchants of Khartoum to form a trading station at Itang and another at Gambela, both of which are situated on the River Baro. A regular steamship service is about to be organised. For some time to come this trade is likely to be conducted through Egyptian channels. This permission to establish trading houses has only just been granted, and it behoves English manufacturers to be first in the field, not forgetting to protect their trade marks in Egypt or the Soudan.

## PHYSICAL SOCIETY.

At a meeting of this society on June 16, Prof. J. H. Poynting, F.R.S., president, in the chair,

A paper "*On the Ratio between the Mean Spherical and the Mean Horizontal Candle Power of Incandescent Lamps*" was read by Prof. FLEMING. This paper contains a theoretical deduction from first principles of experimental results given by Mr. G. B. Dyke, B.Sc., in a paper read before the Physical Society on Nov. 11, 1904, respecting the ratio of the M.S.C.P. of incandescent electric lamps to the M.H.C.P. taken when the lamp was rotating round a vertical axis. In the case of nine different types of electric incandescent lamps, this ratio was found to be a number near 0·78. The author shows, by discussing the simple case of linear filament, that the ratio of the M.S.C.P. to the horizontal candle-power for this last case must be represented by the value $\pi/4=0\cdot785$, and, hence, that the constant ratio found experimentally by Mr. Dyke necessarily follows as a simple consequence of the fact that the light sent out in any direction from each unit of length of an incandescent filament varies as the cosine of the angle of inclination of the ray to the normal to the filament. In the paper it is shown also how a simple correcting factor may be obtained for reducing the actual horizontal candle-power of a linear filament of finite length to the candle-power in the same direction which would be found if the elements of the filament were concentrated on the axis of the photometer and all normal to it. If $\phi$ is the angle subtended by any linear filament at the photometer disc, then the expression $\frac{1}{2}\{\cos^2\phi+\phi\cot\phi\}$ is the correcting factor which must be applied to correct the candle-power of the filament in the sense indicated above. From this expression is derived a general expression for the ratio of the mean spherical to the mean horizontal candle-power of a filament of finite length when the measurements are made at such a distance that the length of the filament subtends a sensible angle at the photometer. The result of experiments are also described, justifying the assumption of the above cosine law of radiation.

Mr. G. B. DYKE briefly described the experiments which had been performed to justify the law.

Mr. L. GASTER thought that the subject discussed by Prof. Fleming deserved considerable attention at the hands of lamp manufacturers. Owing to the improvements made in recent years in the manufacture of incandescent lamps it is advisable, in comparing their relative merits, to consider the mean spherical candle-power given out, and to determine the total flux of light per watt consumed, thereby conveying an accurate meaning as to the efficiency of the lamp as an energy-transforming device.

Dr. CHREE pointed out that the quantity $\frac{1}{2}(\cos^2\phi+\phi\cot\phi)$ was based on a calculation which supposed the photometer disc exactly opposite an *end* of the filament and required modification when this was not the case. When $D/l$ was so large that $\phi$ was small, higher powers of $\phi$ being neglected, the quantity reduced to $1-\frac{2}{3}\phi^2$; but if the photometer disc were opposite the *centre* of the filament $\phi$ had to be replaced by $\phi/2$, and the departure of the quantity from unity was reduced to a quarter. He remarked that the quantity $\frac{1}{2}(\cos^2\phi+\phi\cot\phi)$ had to be applied as a *divisor* to the observed illumination to deduce what the result would be under the ideal conditions when $D/l$ was so large that $\phi$ was negligible; and he was doubtful whether the language employed, especially the description of the quantity as a "correcting factor," was sufficiently free from ambiguity.

Prof. J. A. FLEMING said he had tried to impress upon lamp users the advantage of expressing candle-power in terms of the total flux of light per watt consumed. Now that a simple relation had been established between M.S.C.P. and M.H.C.P., there was no excuse for expressing the candle-power of a lamp as *its maximum* horizontal candle-power.

Dr. H. A. WILSON read a paper on "*The Electrical Conductivity of Flames.*" The paper contains an account of a series of experiments on the conductivity of a coal-gas flame for electricity between platinum electrodes immersed in the flame. The variation of the current with the distance between the electrodes and the fall of potential along the flame are investigated by using a special burner producing a long narrow flame. The burner consists of a fused quartz tube with a series of small holes parallel to its diameter. The electrodes are two parallel discs of platinum, one fixed at one end of the flame, and the other capable of movement horizontally in the flame, so that it can be placed at any desired distance from the fixed electrode. The current through the flame was measured by a moving-coil galvanometer, and the potential difference between the electrodes by an electrostatic voltmeter. The quartz-tube burner being a good insulator enables a current to be passed from one end of the flame to the other without fear of any of it going through the tube instead of through the flame. It thus enables the effect of putting salts into different parts of the flame to be easily studied.

Dr J. A. FLEMING said that the paper was of practical interest, and described some experiments he had made to utilise the properties of flames rendered conducting by potassium salts in the construction of a sensitive telegraphic relay.

Mr. W. DUDDELL drew attention to the similarity of the phenomena described to those exhibited by electric arcs. He asked the author if he had considered the possibility of using a conducting flame as a high-voltage rectifier. Also, had the author tried sodium salts and what were their effects compared with those of potassium.

Dr. W. WATSON asked if the drop of potential at the negative electrode depended upon the temperature of the electrodes.

Dr. H. A. WILSON, in reply to Mr. Duddell, said that the salts of cæsium, rubidium, potassium, sodium, and lithium imparted conductivity to flames in the order named. This order was also the order of the atomic weights. He had found that a flame could be used as a rectifier when using alternations about 100~ per second, but was not

Digitized by Google

sure whether it would rectify rapidly alternating currents. In reply to Dr. Watson, he said that the temperature of the electrodes exercised a great influence. An increase in the temperature of the electrode diminished the drop of potential at the electrode.

A paper on "*Contact with Dielectrics*" was read by Mr. ROLLO APPLEYARD. The object of the paper is to examine (1) whether tinfoil electrodes, pressed against a sheet of dielectric by indiarubber discs, enable accurate determinations of dielectric resistance to be made; (2) the effect upon dielectric resistance of change of load on such tinfoil electrodes in the case of presspahn; (3) the effect upon dielectric resistance of increase or decrease of voltage in the case presspahn between tinfoil electrodes; (4) the rate and direction of the change of deflection in direct-deflection tests on presspahn, and to determine in how far these changes result from surface conditions and in how far from internal stresses; (5) the effect of reversals of voltage upon dielectric resistance; (6) the effect of prolonged "electrification"; (7) to indicate the probable limits of accuracy with mercury electrodes; (8) to point out that Price's guard wire can be used in sheet tests to eliminate leakage over the sheet surface as well as over the instruments. Among the conclusions arrived at are the following: (*a*) Except in the case of homogeneous dielectrics, it is misleading to deduce specific values referred to unit cube of the material from the results of tests on sheets. (*b*) With tinfoil electrodes, the apparent resistance of presspahn diminishes as the load increases, and it attains a fairly constant value at a load of 400 grm. per cm.$^2$ (*c*) If, with tinfoil electrodes, the load is gradually diminished after a load of 543 grm. per cm.$^2$, the resistance gradually rises, but the rise is less rapid than the diminution in the former case (*b*). (*d*) When the full load with tinfoil electrodes is again restored the resistance falls to its minimum value. (*e*) For small loads, with tinfoil electrodes, the second-minute deflection is in general greater than the first-minute deflection. As the load increases, a point is reached at which these deflections become approximately equal. For loads greater than about 360 grm. per cm.$^2$, the first-minute deflection is in general greater than the second-minute deflection. (*f*) Increase of voltage, with tinfoil electrodes, especially with small loads, behaves like increase of load, apparently increasing the contact area and diminishing the observed dielectric resistance. Load, voltage, and the normal effect of "absorption" thus combine to determine the ratio of the first-minute deflection to the second-minute deflection. (*g*) When mercury electrodes are used, the dielectric resistance as measured at different voltages is sensibly the same, even for abrupt and great changes of voltage. (*h*) When mercury electrodes are used the second-minute deflection is in general never greater than the first-minute deflection. The inference is that when, with tinfoil electrodes, the converse is the case, it arises from imperfect contact, and not from the material itself. (*i*) When mercury electrodes are used the dielectric resistance as measured with a voltage applied in a given direction is sensibly the same as that measured with the voltage reversed, and this equality appears to become greater after a few reversals. (*j*) There is a critical load at which tinfoil electrodes yield fairly accurate results. With greater loads there is danger of crushing the material. With a less load the contact is faulty.

Mr. DAVID OWEN, in reference to the variation of apparent resistance with the volts applied in the case of the experiments made by the author where tinfoil electrodes were used, pointed out that an effect of the same kind takes place in the case of the leakage resistance of condensers of paraffined paper and tinfoil. If the insulation resistance be measured by observing the rate of leak of the condenser, the curve of volts and time drops more slowly than according to the exponential law. The same result is obtained if the current maintained by the application of a steady voltage across the condenser terminals is measured by a galvanometer in series. For such a condenser a recent test gave an apparent resistance of 100 megohms for a P.D. of four volts, but this value steadily dropped with rise of voltage, and was 41 megohms for 20 volts. Though the voltage here used was much less than those applied by the author, the effect in question is the same in kind and in degree.

Mr. A. CAMPBELL said Mr. Appleyard's paper was an interesting contribution to our knowledge of a difficult but practically important subject. He had established the advantages of mercury electrodes. Mr. Campbell remarked that he had used tinfoil and indiarubber electrodes for the last 15 years, and mentioned that before they were adopted at the National Physical Laboratory for Mr. Rayner's and other work they were put through a series of tests with varying weights, and from the observations a working pressure was chosen which gave tolerably accurate results. He had also tried guard wires with several kinds of sheets, and found that the surface leakage was negligible. In Mr. Rayner's experiments at high temperatures, the changes due to a fall of temperature of a few degrees were so enormous that any inaccuracy due to the clamps was of trifling importance. Mr. Campbell mentioned that when measuring the capacities of thin sheets, tinfoil electrodes gave results which in some cases varied with the applied pressure. For example, with dry paper as dielectric, increase of pressure gave considerable increase of capacity, and since in this case the contact does not matter, the effect must have been due to approach of the electrodes. If the paper be blackleaded the change of pressure has less effect. He therefore suggested that in cases where mercury was inconvenient the use of blacklead might be of advantage.

Dr. H. A. WILSON expressed the opinion that when using mercury electrodes the diminution in resistance might be due to compression of the dielectric caused by the pressure of the mercury, rather than to better contact between the mercury and the dielectric.

Mr. W. A. PRICE said that the question of insulation tests was an important and far-reaching one. Dr. Wilson had suggested that the pressure of the mercury might cause a change of form, but he did not think that pressures so small would produce any appreciable change. The author had shown that provided you obtained good contact between the electrodes and the dielectric, you could obtain constant values for the insulation resistance.

Prof. W. CASSIE suggested that the pressure might be applied to the tinfoil electrodes by placing a sheet of indiarubber over each of them, or by putting the plate of dielectric with its tinfoil electrodes in a flat indiarubber bag and pumping out the air under the indiarubber. Thus the pressure of the atmosphere would produce more uniform and effective contact of the tinfoil with the dielectric. The pressure obtainable in this way might have any desired value up to about a kilogramme per square centimetre.

Mr. R. APPLEYARD, in reply to Mr. Campbell's suggestion with regard to the use of blacklead, pointed out that it was necessary to guard against moisture. Spurious effects might be introduced by electrolytic action.

# LEGAL INTELLIGENCE.

## ACCIDENT.

At the Essex Assizes, before Mr. Justice Bucknill, an action was brought by Mr. Grant, hotel proprietor, to recover damages from Messrs. J. G. White and Co. for personal injuries sustained by plaintiff through alleged negligence on the part of the defendants in not properly protecting an excavation. Defendants denied negligence.

Plaintiff was driving in a dog cart in June of last year about 11 p.m. He had two lights on his cart, and was travelling at seven or eight miles an hour. When he reached Barrack-street he saw a red light in the middle of the road, and, continuing to drive on, on his near or proper side, the rear wheel of his cart tilted up over a heap of granite setts, with the result that the off wheel dropped into an excavation which was made in connection with the construction of the tramways. Plaintiff was thrown out, rendered unconscious, and so severely injured as to necessitate considerable medical attendance and care. It was stated on behalf of the plaintiff that the construction of the tramlines had led to the traffic being diverted to one side of the tramlines, leaving about 10ft. available for traffic. The plaintiff, who had not driven that way previously while the excavations were being carried on, did not notice that the traffic had been so diverted, as there was nothing to indicate it.

Counsel for the defendants argued that the lights put up by them should have been a sufficient warning.

HIS LORDSHIP, without calling upon counsel to reply for the plaintiff, decided that the defendants had been guilty of negligence. He found that there was no light in the middle of the road in such a position as to indicate to the plaintiff that it was dangerous for him to proceed down the road. The proper and usual course for defendants to have carried out would have been to have had a hanging lamp from a scaffold pole. He did not find that there was any contributory negligence on the part of the plaintiff. Judgment would be for the plaintiff with £200 damages and costs.

## MOTOR REPAIRS.

In the Lord Mayor's Court, before Mr. F. S. Jackson and a jury, the case of the Refuse Destructor Company, Limited (in liquidation) *v.* Toshinsky and Ruchkovitz was disposed of. The plaintiff company claimed £10. 10*s.* in respect of certain repairs to an electric motor machine, at the request of the defendants. The plaintiffs supplied the defendants with a 20 h.p. electric motor. The defendants requested the plaintiffs to see to the motor because it had got out of order. The plaintiffs sent their engineer, one Mr. Wiltshire, who found upon going to the sawmills that the motor had been subjected to negligent treatment. The repairs now sued for were in respect of a sum of 10*s.* for heated bearings, which were put right, and the sum of £10 for repairing a burnt-out armature. When the motor was fitted up by the plaintiffs the defendants were informed that it would be necessary to brush the machine from time to time, and not to allow hardwood dust and oil to accumulate. The motor, being used in a sawmills, could not be kept absolutely free from dust, but the defendants allowed an accumulation of wood-dust and oil to occur, and the result was to cause a "bridging" of parts of the motor that were insulated. This, acting as a conductor, broke down the insulation and caused the damage to the armature. The question for the jury was whether the damage to the armature was caused by defective workmanship or negligent treatment.

For the defence, Mr. EWARD KEIL, engineer, said that when first employed the motor was connected to a countershaft. The distance between the countershaft and the motor was about 9ft., and it was impossible to get the motor to work properly, and they could never get a 20-h.p. drive out of it. The effect of so short a drive was that the belting was required to be so tight that the bearings became heated immediately. He had altered the length of drive and connected the motor to the main shaft, and it was now working admirably.

Judgment for plaintiffs for amount claimed.

# COMPANIES' MEETINGS AND REPORTS.

## J. G. WHITE AND CO.

The sixth ordinary general meeting of this Company was held on Friday last under the presidency of Lord Arthur Butler.

The CHAIRMAN, in moving the adoption of the report, stated that the present position of the business was very satisfactory, as the Company had in hand work of very considerable magnitude—in fact, con-

Digitized by Google

siderably more than it had ever before at any one time. The contract work actually in hand exceeds £1,750,000, some considerable portion of which is being carried out in foreign countries, where, it is anticipated, the profits will be considerably larger than on tramway contracts carried out in Great Britain. A number of contracts have been secured for the complete construction of tramways, which indicates that the scope of the business is widening. In addition, arrangements have been made for securing business in Brazil.

Mr. J. B. WHITE seconded the motion, which was carried unanimously.

The CHAIRMAN next moved: "That a dividend, free of tax, at the rate of 6 per cent. per annum, on the cumulative preference shares for the year to Feb. 28, 1905, be declared."

This was seconded by Mr. J. B. WHITE, and agreed to.

The CHAIRMAN also proposed: "That a dividend, free of tax, at the rate of 6 per cent. per annum, on the ordinary shares for the year to Feb. 28, 1905, be declared."

Mr. J. B. WHITE seconded the motion, which was unanimously agreed to.

The retiring directors, Mr. W. C. Burton and Lord Arthur Butler, were unanimously re-elected, on the motion of Mr. J. B. WHITE, seconded by Mr. A. N. CONNETT; and Messrs. Monkhouse, Stoneham, and Co. were reappointed auditors, on the motion of Mr. WOOLLETT, seconded by Mr. BURTON.

A vote of thanks to the chairman concluded the proceedings.

## EDMUNDSON'S ELECTRICITY CORPORATION.

The report for the year ended March 31 last, to be presented at the meeting on the 6th prox., states that, including £13,923 brought forward from last year, the net profit, after payment of debenture interest, amounts to £68,915. The directors recommend a final dividend on the ordinary shares at the rate of 9 per cent. per annum, making 7 per cent. for the year, and a dividend at the rate of 7 per cent. on the 10,000 ordinary shares issued in November, 1904, to be added to reserve fund £6,635, leaving to be carried forward £15,007. The trading profit for the first time shows a small decrease, but, on the other hand, the income derived from investments has considerably improved. It is on a continuance of this improvement that the progress of the Corporation will in future mainly depend. During the year 10,000 preference shares, 10,000 ordinary shares, and £37,804 debenture stock have been issued. The premiums received in respect of these issues, less expenses, amount to £13,364, and have been added to the reserve fund, which, with the contribution proposed to be made from revenue account, will be thereby increased to £90,000. The growth of the electric lighting and power stations in which the Corporation is interested continues to be satisfactory, the lamp connections having increased from 568,549 to 761,453 during the year. The central station at Newbury was completed and opened in January. Good progress has been made in connection with the central stations at Inverness and Ramsgate, both of which will be opened during the next few months. These will complete the whole of the central stations which the Company at present proposes to erect.

## UNITED RIVER PLATE TELEPHONE.

The directors, in their report, say that the gross receipts in sterling for the year in the River Plate were £151,084, as against £134,824 for last year. Deducting debenture interest, dividend on preference shares, and interim dividend on ordinary shares, and adding interest on investments and transfer fees there remains a profit of £41,662, to which must be added £3,428 brought forward from the previous year, leaving an available balance of £45,091. Owing to the renewal and improvement of some of the most important trunk lines and the general rise in wages consequent on the enhanced cost of living in Argentina, there has been an exceptional increase in the River Plate expenses. After putting aside £10,000 for renewal of plant and transferring the sum of £15,000 to the reserve fund, the directors recommend that a final dividend of 5 per cent. be paid upon the ordinary share capital of the Company, making, with the interim dividend paid Dec. 31 last, a return of 8 per cent. for the year, free of income tax, and that the balance of £2 591 be carried forward. The business of the Company continues steadily to increase, and, as anticipated, further capital is required. It is therefore intended to make an issue of £50,000 in ordinary shares, which will be offered to the ordinary shareholders at par.

## NEW COMPANIES REGISTERED.

**Electrical Distribution of Yorkshire, Limited.** — Capital, £10,000. Objects: To carry on in the West Riding of Yorkshire or elsewhere the business of suppliers of electricity and gas for light, heat, motive power or otherwise, electricians, electrical, chemical engineers, etc.

### Lien Discharged.

**British Tramways and General Construction Company, Limited, London, E.C.** — Discharge registered June 20 of lien registered April 22, 1904, for £120,000.

## APPOINTMENTS VACANT.

**Shift-Engineer Foreman.** Applications to Box S 92, *Electrical Engineer* Office. See advertisement in last issue.

**Electrical Engineer**, Handsworth Urban District Council. Salary, £350 per annum. Applications by June 30.

**Principal** of the Paddington Technical Institute, Saltram-crescent, W. Commencing salary, £500 a year. Applications to the London County Council by July 3. See advertisement in last issue.

**Electrical Draughtsman**, Metropolitan Asylums Board, London, E.C. Salary, £125 per annum. Applications to Mr. T. Duncombe Mann, clerk, by 10 a.m. on July 3.

**Tramway Manager**, Leyton Urban District Council. Salary, £300 per annum. Applications by 12 noon on July 1.

**Shift Engineer**, Bursalem electricity works. Applications by July 6. See advertisement.

**Various.**—Head of electrical engineering department; salary, £200 per annum. Head of civil and mechanical engineering department; salary, £200 per annum. Assistant for building construction, etc.; salary, £130 per annum. Halifax Education Committee. Applications by July 11. See advertisement.

## CONTRACTS FOR ELECTRICAL SUPPLIES.

**Fregenal (Spain).**—The Municipality require tenders for public electric lighting. Tenders by July 3.

**Mazarron (Spain).**—The Municipality require tenders for public electric lighting. Tenders by July 5.

**Liria (Spain).**—The Municipality require tenders for public and private electric lighting. No date fixed.

**La Rambla (Province of Cordoba, Spain).**—The Municipality require tenders for public electric lighting. Tenders by July 1.

**Cataquoxes (Spain).**—The Municipal Electric Light and Power Company require tenders for electric plant. Tenders by July 1.

**Gillingham.**—Tenders are invited for one water-tube boiler and superheater, for the Electricity Committee. Tenders by July 3.

**Leigh (Lancs.).**—Tenders are invited for the supply of one water-tube boiler for the electricity department. Tenders by July 1.

**Fulham.**—The Council invite tenders for extension of cables, feeders, etc. Tenders by noon on July 12. See advertisement in last issue.

**Ilford.**—The Urban District Council invite tenders for the supply of ·4in. and ·25in. concentric cable. Tenders by 4 p.m. on July 11. See advertisement.

**London.**—The London County Council invite tenders for two low-tension feeder switchboards. Tenders by 10 a.m. on July 11. See advertisement in last issue.

**Bradford.**—The Education Committee invite tenders for the lighting of block A of the Grange-road new Council schools by electricity. Tenders by 10 a.m. on July 3.

**Bradford.**—The Corporation invite tenders for electric lighting installation in connection with the alterations at the central public library, Darley-street. Tenders by 12 noon on July 3.

**Dewsbury.**—Tenders are invited for the wiring and fittings required for lighting the warehouse in Wellington-road belonging to the Dewsbury Pioneers' Industrial Society, Limited. Tenders by July 5.

**Burton-upon-Trent.**—The Corporation invite tenders for the electrical equipment on the overhead system of about 1¾ miles of tramway (Contract No. 10). Tenders by noon on July 7. See advertisement in last issue.

**Loughborough.**—Tenders are invited for the supply of materials and stores for the year ending July 31, 1906, for the electricity works. Tenders to the Borough Electrical Engineer by July 18. See advertisement.

**Brighton.**—The Town Council invite tenders for supply, erection and maintenance of a 260-cell storage battery, having a capacity of 1,000 ampere-hours, at their power station, Southwick. Tenders by 10 a.m. on July 3.

**Alicante (Spain).**—The Harbour Board (Junta des Obras del Puerto) require tenders for two electric cranes, capable of lifting 10,000 kc. and 1,500 ko. respectively. Tenders by Sept. 15. Estimate, 107,010·10 pesetas.

**Stalybridge.**—The Stalybridge, Hyde, Mossley, and Dukinfield Tramway and Electricity Board require tenders for the supply, delivery, and erection at the Stalybridge sub-station of a 400-kw. motor-generator, together with the necessary switchgear for same.

**Neath.**—The Rural District Council invite tenders for the supply, etc., of electric light and power mains, sub-stations, switchboards, feeding pillars, switch pillars, excavations, and other works in connection within their area. Tenders by July 17. See advertisement.

## RESULTS OF TENDERS.

**Port Elizabeth.**—The tender of Messrs. Wills and Davey has been accepted, at £8,985, for the electricity works.

**Bristol.**—The Docks Committee have accepted the tender of Messrs. Stothert and Pitt, Bath, for the construction, delivery, erecting in place, fitting, testing, and maintenance for 12 months after completion, of four two-ton movable electric jib cranes, and one three-ton movable electric jib crane to be erected on the adjoining wharf at Canons Marsh.

**Colliery Contracts.**—Messrs. Bruce Peebles and Co., 25, Victoria-street, report the following recent contracts for colliery plant: Lambton

Digitized by Google

Collieries, Durham, 2 800 h.p. in hauling, pumping, and ventilating motors; average size, 150 h.p. Risca Collieries, South Wales, 1,800 h.p. in pumping and hauling; average size, 180 h.p. Darbishires Quarries, North Wales, 1,500 h.p. motors varying from 50 to 150 h.p. Bow Hill Collieries, 500 h.p. in pumping and hauling. The total horse-power aggregates over 6,000, and the value of the orders aggregates over £40,000.

**Hammersmith.**—The Borough Council have received the following tenders for the cable required for connecting up the new generating plant to the main switchboards:

| | | | |
|---|---|---|---|
| Henley's Telegraph Works Company | £294 | 0 | 0 |
| Western Electric Company (accepted) | 294 | 18 | 9 |
| St. Helens Cable Company | 300 | 0 | 0 |
| Siemens Bros. and Co. | 317 | 5 | 0 |
| British Insulated and Helsby Cables, Limited | 338 | 0 | 0 |
| Glover and Co. | 357 | 3 | 9 |

**St. Pancras.**—The Borough Council have received the following tenders for the supply of arc lamp carbons for 12 months:

| | | | |
|---|---|---|---|
| Campagnie Française | £385 | 5 | 8 |
| G. Braulik | 463 | 13 | 2 |
| Siemens Bros. and Co. | 466 | 0 | 11 |
| De Grelle and Houdret | 471 | 19 | 1 |
| Sloan Electrical Company (accepted) | 476 | 19 | 0 |
| Mayer and Co. | 464 | 5 | 5 |
| D. McNaughton (Henrion carbons) | 494 | 17 | 4 |
| Brush Electrical Company | 500 | 9 | 6 |
| Crompton and Co. | 492 | 18 | 3 |
| General Electric Company | 510 | 15 | 2 |
| Johnson and Phillips | 505 | 5 | 4 |
| Electrical Company | 544 | 0 | 8 |
| British Thomson-Houston Company | 544 | 17 | 0 |
| Veritys, Limited | 543 | 11 | 7 |
| International Electric Company | 585 | 14 | 5 |
| Henckel and Jordan | 709 | 16 | 1 |
| Rumney and Rumney | 1,629 | 13 | 9 |

# BUSINESS NOTES.

## TRACTION.

**Cardiff.**—The accounts for the year, over which there has been a good deal of speculation, are expected to be presented to the Finance Committee this week.

**South Shields.**—The Local Government Board has completed its enquiry into the application of the Corporation for sanction to a loan of £15,625 for additional tramway plant.

**Heywood.**—Sanction has been received to the borrowing by the Corporation of £37,200 for electrifying the tramways within the borough and the extension of the electricity works.

**Belfast.**—At a meeting of the inhabitants a resolution was passed expressing "dissent and strong disapproval" of the suggested 1d. stages, which, in regard to the Falls-road district, were characterised as "unjust and unfair."

**Erith.**—At the meeting of the Urban District Council, the Electric Lighting and Tramways Committee reported that they hoped at the next meeting to be able to state when the whole of the tramway works are likely to be completed.

**Leith.**—The Town Council have had an "instruction" car placed at the tramways depôt in order that the drivers of the present horse cars may gain a practical knowledge of the working of electric cars before the new system of tramways is installed.

**Private Bills in Parliament.**—In the House of Lords the following Bills have been read a third time: Central Electric Supply, County of London Electric Supply Company, London United Tramways (Extension of Time). In the Commons the following Bills have been read a third time: London County Council (Money), and Metropolitan Electric Tramways.

**Huddersfield.**—Some rather severe strictures were passed on the motormen at the meeting of the Corporation in connection with the recent accidents. In their defence a councillor stated that in the case of the Newsome-road accident the brakes were tested, and on the first test were found to be all right, but tested again they failed. The brake was again tried, and it then acted all right.

**Warrington.**—Colonel von Donop last week inspected on behalf of the Board of Trade the new Stockton Heath tramway extension. At present the cars only run to Stafford-road, whereas the centre of the village is Victoria-square, 250 yards away. The great difficulty in making the extension has been the swingbridge over the Ship Canal, but the engineers have successfully surmounted this. At the trial spin there was some delay owing to some dirt having affected the switch under the bridge, but the run over the bridge to the square was then accomplished without mishap. The extension has cost about £11,000.

**Oxford.**—We recorded last week that at a public meeting a resolution was carried in favour of deferring the acquisition of the company's undertaking until further information had been obtained in regard to methods of conveyance generally. A special meeting of the Corporation was held last week to consider the question of purchase in the light of this resolution, when, after considerable discussion, it was decided to acquire the company's undertaking, and the follow supplementary proposition was agreed to: "That the seal of the Corporation be affixed to an agreement to carry into effect the resolutions already adopted by the Council, and that it be referred to a special committee to settle the terms of the agreement, and to take all such necessary steps as may arise out of the transaction."

**The Underground.**—Electric trains, four to the hour, will commence running to-morrow between Ealing and Whitechapel. Simultaneously the Inner Circle service of the Metropolitan Railway will come into electrical operation. As announced earlier in the year, the preparations were entirely completed for this change, but owing to the delay in the delivery of the sister companies' rolling-stock the transformation has been delayed. It is expected that the District Railway circle service will be worked by electricity in its entirety shortly after the beginning of next month, but a definite announcement will be made in a few days.

**St. Helens Tramway Strike.**—Replying to a question at the meeting of the Liverpool Corporation, Sir Charles Petrie explained that they had no arrangement whatever with the St. Helens Tramways Company. The arrangement was with the South Lancashire Company, and not the St. Helens Company, as to the working of that portion of the line between Knotty Ash and Prescot. There was a strike in connection with the St. Helens Company, but the Liverpool Corporation had nothing to do with that, and took no sides in the matter. They simply undertook to work this particular length of line between Knotty Ash and Prescot for the benefit of the passengers, and had not interfered in any way. The matter was now at an end, as the South Lancashire Tramways Company had recommenced to work the line.

**Rating of Tramways.**—At the invitation of the town clerk of Wakefield a conference of representatives from the local authorities through whose areas the lines of the Wakefield and District Light Railway run, was held at the town hall last week. The town clerk asked for support in a proposal to contest the refusal of the company to pay in full the district rate levied by the Corporation, on the ground that they are entitled to be rated at one-fourth only. The Corporation, on the other hand, contend that the light railway is not a railway within the meaning of Section 211 of the Public Health Act, 1875, and that the company are not occupiers of land used only as a railway. The delegates were unanimously of opinion that the Wakefield Corporation should be supported in its action, and they promised to report to their respective authorities.

**Glasgow.**—The following figures in regard to the Corporation tramway accounts for the past year are supplementary to those we gave last week: Expenditure—traffic, £217,873; general, £75,119; repairs, £68,640; power, £25,535—total, £387,167. Adding amount set aside for renewal and depreciation (£153,334) the total is £540,501. Deducting this amount from the gross revenue there remains a balance of £227,403. From this the following items have also to be deducted: lease of Govan lines, £5,080; lease of Paisley District Tramways, £915; interest, £49,906; sinking fund, £46,920; income tax, £5,434; parliamentary expenses, £891; common good, £25,000—total, £134,146. This leaves a net surplus of £93 257, of which the committee propose to appropriate £68,500 for special depreciation, and to carry the balance to reserve fund.

**Bournemouth.**—Extension to Christchurch is being pushed forward as expeditiously as possible by Messrs. J. G. White and Co., the contractors, who have about 100 men busily engaged in preparing the track. The continuance of the fine weather will facilitate the work, and no delay is expected, as all the materials have been delivered and the contracts settled. The first section of the line will, it is confidently hoped, be open for use on August Bank Holiday. This will give a ride from Pokesdown to Tuckton Bridge. Onwards the work is of much greater magnitude, for it involves the reconstruction of Tuckton Bridge. The second section will probably be finished in October, and by November the contractors hope to have completed the undertaking. The construction of the line will necessitate other work, and the telephone and telegraph wires, instead of running overhead, will be carried underground.

**London United Tramways Co.**—The Highways Committee of the Kingston Town Council have resolved that the company shall be required to lay their tramways in the streets where tramways are now being laid at such levels as shall be consistent with the wood paving hereafter of such streets throughout their entire width. The Council have received from the company plans for the widening of the bridge in St. James's-road, for the widening in Clarence-street from Church-street to Fife-road, for the widening in Clarence-street from Fife-road to the King's Arms public-house, for the widening at the junction of Penrhyn-road and St. James's-road, and in respect of crossing places and levels at Surbiton-road. A reply has been received from the company stating that the matter of the construction of the length of tramway along Richmond-road from King's-road to the borough boundary would be considered by the directors.

**Brighton.**—Although there is a deficit on the past year's working of £320, the system showed a marked improvement over last year, when the deficit amounted to £4,778. The chief figures for the year ending March 31 last are: income, £250,339. 11s. 7d.; expenditure, £38,495. 13s. 9d.; leaving a gross balance of £11,843. 17s. 10d. Out of this interest charges absorb £8,084, and sinking fund charges £4,080. 16s. 10d., leaving a deficiency of £321. 11s. 11d. The principal items of expenditure for 1905 and 1904 respectively are; traffic expenses, £15,956. 15s. 3d. (£17,153. 12s. 9d.); power expenses, £11 350. 8s. 5d. (£11,093. 13s. 6d.); repairs and renewals, £6,476. 7s. 9d. (£8 487. 2s.); management and general expenses, £3,813. 19s 8d. (£3 260. 7s. 11d.); rents, rates, and taxes, £898, 2s. 8d. (£223. 13s. 4d.). The population served by the tramways is 126,250, and the car miles run during the past year total 1,152,828, the track mileage being 9 miles 3 furlongs 200 yards, of which 7 miles 5 furlongs 137 yards are double track, and 1 mile 6 furlongs 63 yards single track. The units of energy consumed were 1,816,067, the number per car mile being 1·57. During the past year the capital expenditure amounted to £30,402. 7s. 10d., the total expenditure to date being £274,070.

**Kirkcaldy-to-Leven.**—At the monthly meeting of the Kirkcaldy District Committee of the County Council the clerk reported that he had received the opinion of Mr. Campbell, K.C., in connection with a proposal by Mr. Sellon, engineer of the Wemyss tramways, that at certain points where the tramways came on to the road the rails should be laid at the side of the road, the tramway track being about 6in. above the surface of the road. In a lengthy opinion counsel pointed out that the gross margin at the side of the road was under the control of the District Committee, but he thought it very doubtful if that fact made them occupiers of the land abutting on the road or adjoining the road within the meaning of Section 4 or Section 22. He further stated that the duty of the District Committee was to maintain the road in the interests of the public, and not to sanction encroachments on the carriageway or margin. If they agreed to Mr. Wemyss's proposals, they would be liable for any damages to members of the public resulting from the alterations which they had authorised. A letter was read from Mr. Sellon, in which he said he differed entirely from Mr. Campbell's opinion, and he had not the slightest doubt he could get it reversed 20 times over by counsel who knew anything at all about parliamentary work. They were aware, no doubt, that he did not require the consent of the County Council in this case, neither did he require the matter to be referred to eminent counsel, and he accordingly advised them formally that in three weeks he would order the rails for the purpose of constructing the tramway section necessary for the construction of the line down the centre of the Randolph-road, leaving it entirely for the County Council to consider within that time whether they would not prefer to suggest to him some course beneficial alike to all parties without the interference of outside parties. After some discussion, it was agreed to reply to Mr. Sellon that while the District Committee had been all along willing to meet Mr. Wemyss's views in connection with the tramways, they could not do otherwise than be guided by the opinion of counsel.

**Edinburgh-Queensferry.**—A special meeting in committee of the Edinburgh Town Council was held last week for the purpose of considering a report by the Lord Provost's Committee submitting draft agreement between the promoters of the Queensferry tramways and the Corporation. We gave the main points of the agreement last week. The town clerk, in explaining the agreement, pointed out that the effect of the Corporation's refusal, if they did refuse, to give consent in any form to this tramway proposal, although they had nothing to do with the consent of other people, would be to kill the proposal for the present. The Dean Bridge route was the one the company would want if they could get it, but that obviously raised the question of the widening of the Dean Bridge, and that would entail a great deal more money than the company could afford to pay. The committee had only refrained from saying no to the Bedford Bridge route, which obviously was only an alternative to the Dean Bridge route, in order to allow the Town Council time to say either yes or no to that route. The other line was to connect Comely Bank with Blackhall. The company would do it, and Comely Bank would then become another Pilrig. The committee recommended giving consent to the company to come in from Blackhall to Comely Bank, but reserved to the Town Council to consider, as they would have to do, whether they would themselves go to Blackhall or convert the route up to Frederick-street into electric traction. What the document did was to give the Corporation absolute power to take at reasonable terms the part within the city, and power to acquire on reasonable terms outside lines. Some discussion took place on the question of the conditions of purchase. The Corporation may, on six months' notice, require the company to sell the tramways at a price equivalent to the then structural value as determined by an arbitrator, but not exceeding the cost price minus 2½ per cent. written off for depreciation, and with a certain bonus added if purchased at various periods prior to the expiry of 21 years. Payment for wayleave, ½d. fares, season tickets, advertisements, a time limit, and other matters were all discussed, and then the draft agreement was approved. Meeting again as the Town Council, the agreement was confirmed after a lengthy discussion.

**Manchester.**—The Tramways Committee at their meeting on Tuesday had before them the report and abstract of accounts for the year ended March 31 last. The report states that at the date of the last report the routes open for traffic aggregated 137 miles 1 602 yards of single track. During the year just ended the following extensions have been made and opened for traffic: Middleton-road, 3 miles 718 yards; circular route extension, Hulme Hall-lane to Belle Vue-street, 4 miles 1,543 yards—total, 8 miles 501 yards. The aggregate length of single track open for traffic at March 31, 1905, was therefore 146 miles 343 yards. The revenue account shows total receipts of £631,955. 12s. 4d., against £611,881. 3s. 8d. for the preceding year. The working expenses were £411,497. 3s. 11d., against £391 853. 13s. 11d. The gross profit, with bank interest, totals £222,227. 17s. 6d. After allowing for interest (£52,120), redemption of debt (£35,379), and other charges, there remains a surplus of £101,277. 13s. 10d. Out of this the following sums have been voted: renewals and depreciation account, £70,907; contribution in aid of the rates, £46,000; street improvements round infirmary (interest, etc.), £4,043. 3s. 8d.—leaving a net profit of £120,950. 3s. 8d. The contribution in aid of the rates was increased by £5,000 being tranferred from a reserve fund accumulated in former years, making the total contribution in aid of the rates during the year the sum of £51,000. The total of the borrowing powers is £1,925,000. Powers have been exercised up to £1,515,168, and the gross capital expenditure is £1,587 930. During the year the number of passengers carried was 126 900,875, an increase of over 6,000,000 on the previous year, when the figures were 120,772,368. The car mileage shows an increase of considerably over 1,000,000 miles, the figures being 14,123,124 during last year and 13,617,448 during 1903-4. The percentage of passengers' fares show that 71·94 paid 1d. for the journey, 11·01 paid 1½d., 7·10 2d., and 5·40 ½d. Of the total number of passengers carried 91,281,804 paid 1d. fares. The electrical energy used during the year amounted to 18,854 240 units, against 16,815,764 in the previous year. The average traffic revenue per car mile was 10·68d., against 10·52d., and the average traffic revenue per mile of single track was £4,299, as against £4,468 in 1903 4. The average working expenses per car mile, including power cost, was 6·99d., against 6·78d. The renewals and depreciation fund now amounts to £185,085, against £119,844 in the previous year. The committee had before them a report by the general manager, Mr. M'Elroy, in reference to the application of the motormen, conductors, timekeepers, and inspectors employed on the tramways for an increase at the rate of time and a half for Sunday duty, Good Friday, and Christmas Day. The committee decided that they were unable to comply with the men's request. The report of the general manager states that the concessions already granted to the staff in the Corporation service, as compared with what was received by the men who worked under the old tramway company, amounted to an annual cost on the department of £50,000. If the further concession were granted it would mean an increase of £6,000 to this amount.

## LIGHTING AND GENERAL.

**Stafford.**—There has been an increase of 37 per cent. in the output of the electricity department during the last month.

**Elgin.**—The Duke of Richmond and Gordon proposes to lay cables for the supply of electricity to the village of Fochabers.

**Removal.**—The National Electric Construction Company, Limited, have removed to larger premises at Queen Anne's-chambers, Westminster, S.W.

**Eastern Extension Australasia and China Telegraph Co.**—The directors have declared an interim dividend for the quarter ended March 31 last of 2s. 6d. per share.

**Southwark.**—Councillor Attenborough proposes to move a resolution in favour of selling the electric light undertaking as a going concern "in view of the heavy burden it throws upon the rates."

**Hamilton.**—The Burgh of Hamilton Electricity Supply, for which Edmundson's Electricity Corporation are contractors, have held an exhibition of electrical appliances, extending over four days, in the hall of the Commercial Hotel, Hamilton.

**Wireless Communication with Lightships.**—The Board of Trade and the Trinity House have concluded a contract with Marconi's Wireless Telegraph Company, Limited, providing for the equipment of lightships with Marconi wireless telegraph installations.

**Buxton.**—The accounts of the electricity department for the year ending March, 1905, show a total revenue of £4 212 compared with £3,884 for the previous year, being an increase of £328. The total expenses were £2,727 compared with £2,443 for the previous year, being an increase of £184.

**Edmundson's Electricity Co.**—The directors recommend a final dividend on the ordinary shares of 9 per cent. per annum for the half-year ended March 31, making, with the interim dividend already paid, a dividend of 7 per cent. for the year. They also recommend a dividend at the rate of 7 per cent. per annum on the 10,000 new ordinary shares issued in November, 1904.

**Swansea.**—The *South Wales News* reports that while Mr. Alexander, electrical wire inspector under the Swansea Corporation, was engaged on a raised trolley repairing a wire at the hospital junction, one of the wires was carried away and struck Mr. Alexander, who was thrown to the ground, a fall of 20ft. He was picked up in a semi-conscious condition and conveyed to the hospital, where it was found he had sustained a severe wound on the forehead.

**Technical Education.**—A large variety of practical instances of the work executed by students of technical classes in Great Britain, Ireland, and the Colonies, and by candidates of the City and Guilds of London Institute's annual examination, 1905, is being shown at the North Gallery of the Imperial Institute. The show was opened on Wednesday by Lord Spencer, and will remain open until July 8. With the exhibits we will deal in a future issue.

**Stock Exchange.**—The Stock Exchange Committee have ordered the undermentioned securities to be quoted in the official list: Calcutta Tramways Company, Limited, 32,610 shares of £5 each (£1 paid), Nos. 105,001 to 137,610. Applications have been made to the committee to appoint a special settling day in and to grant a quotation to County of Durham Electrical Power Distribution Company, Limited, 50,000 ordinary shares of £5 each and 50,000 preference shares of £5 each (special application); Hastings and District Electric Tramways Company, Limited, £125,000 4½ per cent. debenture stock.

**Rochdale.**—The accounts of the electricity department for the year ended March 31 give a total revenue of £9,797 and a total expenditure of £4 975, which left £4,822 to be carried over to their revenue account. There was a balance of £622 from last year, and after paying £1,835 interest, £1,200 repayment of capital, £592 sinking fund, a balance of £1,818 remains to be carried forward. The units generated during the year amounted to 1,440,429, of which 1 160 593 were sold to private consumers by meter, 138,087 were used on the works, making a total of 1,298,680 accounted for. The total maximum supply amounted to 908·5 delivered.

**New Issue.**—In order to provide for the completion of the purchase of the undertaking of the Crystal Palace District Electric Supply Company, Limited, and to meet the continuous increase in the company's business, the South Metropolitan Electric Light and Power Company, Limited, are issuing a further £51,708 4½ per cent. first mortgage debenture stock at £105, and a further 16,300 ordinary shares of £1 each, and 32,600 7 per cent. cumulative preference shares of £1 each, at 21s. 6d. per share, payable as follows: on application, debenture stock 5 per cent., ordinary and preference shares 1s. per share; on allotment (including the premium), 25 per cent. and 5s.6d.; on Sept. 1, 1905, 25 per cent. and 5s.; on Jan. 1, 1906, 50 per cent. and 10s.

Digitized by Google

**Norton.**—The Urban District Council are reminding the Northern Counties Electricity Supply Company, Limited, of the agreement the company undertook to establish works within a period of two years, and asking for the reason why the undertaking has not been carried out.

**Bray.**—The Electric Light Committee selected the following three candidates for the post of assistant electrical engineer in order of merit—viz.: (1) Mr. D. E. McDonnell, Macroom; (2) Mr. L. C. Redfern, Southport; (3) Mr. Warren Storey, Dublin—but no assistant is to be appointed.

**Rotary Pumps.**—Messrs. Federico Jarach and Co., Milan, whose foundry and engineering works are at Ghisa, have acquired from Positive Rotary Pumps, Limited, of 23, Northumberland-avenue, W.C., a concession for the manufacture and sale of pumps under their patents throughout the kingdom of Italy.

**Rawtenstall.**—With regard to the steps taken to bring the Town Council's electricity order into operation, it is reported that the Board of Trade have approved the scheme practically in the form submitted to them. The estimates and plans have been prepared for the Local Government Board, and an enquiry will shortly be held.

**Dublin.**—At a special meeting of the Corporation to-day the Electric Lighting Committee will submit a report referring to the delay which has arisen in connection with the extension of the electric lighting system. The committee recommend an application for sanction to a loan of £100,000 for extension of the undertaking.

**Pontypridd.**—The South Wales Electric Power Company are offering to supply electrical energy for domestic purposes in Pontypridd. It being questioned at the last Urban District Council meeting whether the company had a legal right to do so in view of the powers acquired by the Council, it was decided to take counsel's opinion on the matter.

**Bourne.**—Mr. W. E. Milns, of Stamford and Grantham Electricity Works, has prepared a scheme for the establishment of electricity works in Bourne, and this scheme was laid before a special meeting of the tradesmen's association on June 22. Further consideration is being given to the matter, and it is probable that enquiries will be made for firms willing to erect and run such an undertaking.

**Exeter.**—At the last City Council meeting Mr. Roberts, dealing with the electricity undertaking accounts, said that last year's trading not showing a profit was not to be wondered at, considering the changes made at the works and the fact that the price had been lowered to the consumer. He congratulated the committee that it was now putting the accounts in a proper state by facing facts and writing off depreciation, and by no longer carrying forward any unsanctioned loans.

**City of London.**—At last week's Court of Common Council the electrical engineer reported on the leakage of electricity from consumers' lines in cellars under the public ways, and the possible danger of shocks to the public therefrom. It was agreed that the attention of householders should be drawn to the necessity of fixing and maintaining their electric circuits and apparatus in such a manner and conditions as to prevent the possibility of the pavements from becoming charged with electricity.

**London Gazette.**—The first dividend of 1s. 6d. in the £ has been declared in the estate of William Henry Lloyd Watson and George Huntington, electricians, 83, Battersea-rise, London. The first meeting in the estate of Alexander Holmes and Alexander McCallum, electrical engineers, trading as Holmes and McCallum, at Crown Works, Darwen, will be held at 14, Chapel-street, Preston, on July 4, at 10.30 a.m. A first and final dividend of 2¾d. in the £ has been declared in the estate of Arthur Edgar Brooks, electrical engineer, 110, Cheapside, London.

**Battersea.**—The agreement with the London and South-Western Railway Company, relating to the supply of electrical energy for the purpose of their electrical installation, particularly for the lighting and supply of power at the Nine Elms goods yard, has now been completed by the company, and the Council have commenced the supply. A reverse-current circuit breaker is to be provided in connection with the new panel of the switchboard now on order at an estimated cost of £46. The figures for the half year show an increase of 37 consumers for lighting and 11 for power supply, with equivalent increases of 1,254 8-c.p. and 12 h.p. respectively.

**Houghton-le-Spring.**—Permission has been granted to the Durham Electric Power Distribution Company to carry overhead tension wires in the district where underground ones are impossible, subject to an undertaking to conform with the Board of Trade regulations as to the public safety, and an undertaking that wherever the footpaths or roads are damaged by the erection of the poles, the company will put the same into a proper state. The Lambton Collieries Company has been granted permission to carry certain electric light wires above the highways instead of underneath, subject to the company undertaking the public safety, and as far as they can legally do so.

**Agency.**—Messrs. Nalder Bros. and Thompson, Limited, desire us to notify that in future Mr. Ernest Roberts, 6, Holborn-place, who heretofore has had charge of their London district travelling, will not act in this capacity in future, owing to the large increase in his own business, but that any enquiries which he may receive will be attended to as heretofore. Messrs. Frampton, Paine, and Jackson, 29, Old Queen-street, Westminster, will in future represent them in London, and likewise in the Southern, Western, and Eastern Counties, and those districts where they are not at present represented, for ammeters, voltmeters, wattmeters, and circuit breakers and analogous apparatus.

**Aberystwyth.**—At the last meeting of the Town Council the following resolution, passed by a town's meeting, was read: "This meeting desires the Corporation to take into consideration the advisability of introducing electric lighting and a refuse destructor into the borough." The Mayor said that the town's affairs seemed to be reaching a crisis, and it was time for them to consider the question of the destruction of refuse and the desirability of stopping its discharge into the Severn. The refuse, he was told by experts, was suitable for burning in a destructor, and the power derived by the process could be utilised for generating electricity sufficient to provide 1,500 8-c.p. lamps. Mr. John Naylor, of Leighton Hall, was prepared to lease the building and turbines on the Severn-road at a low ground rent for a long term of years. It was decided to convene a special meeting of the Council to consider the question.

**Krupka and Jacoby.**—We are informed that Messrs. Krupka and Jacoby will from to-day cease to act as managers of Siemens Electric Appliances, Limited, and will continue to carry on business on their own account under the name of Krupka and Jacoby at 61 and 62, Watling street, Queen Victoria-street, E.C. They have made arrangements with Siemens Electric Appliances, Limited, under which they will continue to deal in all the electric appliances hitherto sold by them with the exception of fire alarms, the department for which will be transferred to the Woolwich works of Siemens Bros. and Co., Limited. The firm will also act as sole agents for Dr. Albert Lessing, Nuremberg, and as selling agents for Siemens electric lamps, for india-rubber electric light wires and cables manufactured by Siemens Bros. and Co., Limited, and for some of the products of Siemens-Schuckert Werke, of Berlin and Nuremberg, and Siemens and Halske, Berlin and Charlottenburg.

**Shildon.**—On Tuesday took place the formal opening of the electricity works and refuse destructor erected by Messrs. Heenan and Froude, Limited, for the Northern Counties Electricity Supply Company. There is a four-cell refuse destructor of the Heenan patent type worked in connection with two Babcock and Wilcox water-tube boilers, with a combined heating surface of 3,900 square feet, with a regenerator whereby the blast is heated by the waste gases *en route* to the chimney after they have passed through the boilers. The forced draught is promoted by means of a Heenan fan driven direct by a vertical enclosed quick-revolution engine. The furnaces are on the inter-communicating grate system. At the generating station are installed two 90-h.p. compound engines, by Messrs. Allen, Son, and Co., of Bedford. The dynamos are by the Westinghouse Company, and are capable of supplying current for 6,000 8-c.p. lamps. The switchboard, which has been constructed by Messrs. Dorman and Smith, of Manchester, is of the latest pattern. There is also a storage battery of 250 cells.

**Hull.**—An enquiry has been held into an application of the Town Council for sanction to borrow £36,000 for the purpose of increasing the electricity plant. The town clerk, Mr. E. Laverack, said the electric light undertaking had been successful from its inception in 1893, with the exception of the year 1901, when, owing to the high price of coal and other exceptional circumstances, no profit was made. Out of the profits they had paid interest on sinking fund, and the balance had gone to a reserve fund. Those profits had been made notwithstanding a gradual decrease in the charges from 7d. for light and 6d. for power to 4½d. for light and from 2l. to 1d. for power, the latter being governed by the quantities a consumer used. They had also made contributions out of revenue towards the depreciation of the plant which was originally installed, particularly meters. Mr. Bell, the electrical engineer, described the additional plant proposed, and which consists of boilers, dynamos, engines, transformers, cables, etc. He said that the maximum capacity of the existing plant would provide an increase of ½,000 kw. Last year the demand rose from 3,100 kw. to 3,500 kw., and he anticipated a greater demand next year, owing to some large power consumers which had recently been connected.

**St. Marylebone.**—A report of the Electric Supply Committee gives the following details of each consumer's account with the Metropolitan Company for 1904: total number of consumers supplied during the year, 5,801; total number of meters in circuit, 6,482; gross income from sale of current, £133,370. 16s. 9d.; income from meter rents, £4,469. 13s. 1d.; total Board of Trade units sold, 6 289,877; average price obtained per Board of Trade unit (excluding meter rents), 5·089d.; average price obtained per Board of Trade unit (including meter rents), 5·259d. The prices charged to consumers vary considerably. The charge for residential purposes is 6d. per unit; that for trade purposes 5d. per unit, if the consumption exceeds five units per 8-c.p. lamp installed per quarter; if the consumption falls below this, the price charged is 6d. per unit. For certain all-day basement lighting 3d. per unit is charged. In the case of blocks and flats where the supply is given in bulk, and the proprietor takes over all liability as to individual tenants, the company allow a rebate of 20 per cent. off the 6d. rate. For motive-power and heating purposes the indicator system has been introduced, the charges being 3d. per unit for the first two hours daily on maximum load, and 1½d. per unit for all in excess of this quantity. In addition to these standard rates, there appear to be many special agreements with large consumers, or consumers with a special class of supply, such as hospitals. In these cases the rates vary considerably, there being a few consumers at each of the following rates—viz.: 4½d., 4¼d., 4d., 3¾d., 3½d., 3¼d. (less 2½ per cent.), 2½d., 2d., 5½d., and 7d. per unit. The Board of Trade units sold at the various rates per quarter is given as follows: at 6½., 2,527,372; at 5d., 1,982,323; at 3d., 191 321; at 1½d., 59,523; at 4½d., 387,601; at 4¼d., 86 206; at 4d., 955,572; sundry, 99,959—making a grand total of 6,289,877 units. The table shows the total sales in Board of Trade units and money value and average price per quarter as follows: March quarter, 2,034,575 units, value £43,338. 13s. 5d., average price 5·11d.; June quarter, 1,018,298 units, value £21,731. 9s. 3d., average price 5·12d.; September quarter, 869,932 units, value £18,376. 1s. 2d., average price 5·07d.; December quarter, 2,357,072 units, value £49,924. 12s. 11d., average price 5·06d.—total for year, 6,289,877 units, value £133,370. 16s. 9d., average price 5·089d. The proportion of sales per quarter were: March quarter (*a*) sales in Board of Trade units 32·4 per cent., (*b*) income from consumers 32·5 per cent.; June quarter, 16·2 per cent. and 16·3 per cent.; September quarter, 13·8 per cent. and 13·8 per cent.;

Digitized by Google

December quarter, 37·6 per cent. and 37·4 per cent. The ratio of sales at various rates to total was: at 6d., 2,527,372 units, 40·2 per cent. to total; at 5d., 1,982,323 units, 31·5 per cent.; at 3d., 191,321 units, 3·0 per cent.; at 1½d., 53,533 units, 0·9 per cent.; at 4½d., 387,601 units, 6·2 per cent.; at 4¼d., 86,206 units, 1·4 per cent.; at 4d., 955,572 units, 15·2 per cent.; sundry, 99 959 units, 1·6 per cent. The present rates of charge will continue until the end of the year, the Council reserving to themselves the right of altering the same before the expiration of that period.

**Hammersmith.**—Ground is to be purchased for an extra high-tension sub-station in the north of the borough, and a new high-tension cable laid at a cost of £2107. The premises of 22 additional consumers, representing a maximum of 567 8-c.p. lamps, have been connected to the mains, and 15 consumers have been disconnected, the present number of consumers taking current from the mains being 1,592. It has been decided to order six transformers of 100 kw. capacity each and six of 50 kw. capacity, the contract price with the British Electric Transformer Company being £120 and £87. 10s. respectively. When the revised charge for public lighting comes into operation, about 1,000 maximum demand indicators now fixed at consumers' premises will be rendered useless. An offer from the county borough of Hanley to purchase a number of these indicators at the following rates has been accepted—viz., 2½ and 5 amperes 15s. each, 10 to 25 amperes 17s. 6d. to 20s., larger sizes 30s. In continuation of the report noticed by us in March, 1905, with reference to the conversion of the arc lighting system from rectified to alternating current, the following report from the engineer has been submitted to the Council: "The trial circuit in Hammersmith-road is now in working order, and the result of this is in every way satisfactory. The cost of this conversion is £52. 2s. 8d., and this expenditure is justified for the following reasons: (*a*) The light is improved, being more equally distributed along the street instead of concentrated around the posts. (*b*) The lamps have been completely renovated, and are now quite as good as when purchased originally in 1896, and should stand another 10 years' use without any heavy expense for renewals. (*c*) The circuits consist of only 16 lamps, so the pressure on the cables is reduced, thus decreasing the risk of breakdowns, and also minimising the importance of breakdowns owing to the fewer lamps being affected. (*d*) The present system of running 50 rectified arcs on one circuit inflicts great strain upon the cables, and more especially upon the fittings in the posts, with the result that during stormy weather the fittings fail and cause a great deal of trouble and expense. For instance, during the recent bad weather we had trouble with all the rectified circuits, five lamps and one switch were burnt out, and the leads in the posts were damaged, the total cost of these faults amounting to about £25. This happens nearly every time bad weather is experienced, and is a very heavy charge on public lighting. The total cost of converting the whole of the rectified arcs to alternating (without taking credit for any apparatus which will be thrown out of use) will not exceed £500. The cost of upkeep of the present system amounted to £353. 17s. last year, and I anticipate that if the lamps are converted this item will almost disappear. I therefore recommend that the present system of street-lighting be changed from rectified to alternating, section by section until the whole has been completed, and that this work be placed in the hands of the Universal Electrical Company, who carried out the trial circuit alterations." The committee recommend that the work be carried out, and that the order for the same be placed in the hands of the company named.

## PROVISIONAL PATENTS, 1905.

JUNE 19.

12616. **Improvements in and connected with electric railways and tramways.** Alexander Swanson, Cathkin-avenue, Rutherglen, near Glasgow.

12618. **An apparatus for automatically recording the number of times a telephone is used.** Richard Richmond and George Ernest Clare, 74, Woodside, Wimbledon, London.

12645. **Improvements in means for regulating dynamos.** Henry Leitner, 4, South-street, Finsbury, London.

12682. **Improvements in telephone apparatus for use for diving and like purposes.** Alfred Graham and Robert Henry Davis, 4, South-street, Finsbury, London.

12690. **Improvements in intercommunication telephone systems.** Isidore Bernard Birnbaum and Herbert George White, 322, High Holborn, London. (Complete specification.)

JUNE 20.

12725. **Improvements in arc lamps.** Bernard Mervyn Drake, 66, Victoria-street, Westminster, London.

12778. **Improvements in electric unloaders for air-compressors.** Henry Harris Lake, 7, Southampton-buildings, Chancery-lane, London. (The Ingersoll-Sergeant Drill Company, United States.) (Complete specification.)

12791. **Improvements in electric locomotives.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

12792. **Improvements in and relating to dynamo-electric machines.** The Allgemeine Elektricitäts-Ges., 83, Cannon-street, London. (Date applied for under Patents Act, 1901, Sept. 17, 1904, being date of application in Germany.) (Complete specification.)

JUNE 21.

12822. **An electric door-locking device.** Charles Peter, Zurich-Langnau, Switzerland. (Complete specification.)

12818. **An improved electric safety switch having or possessing a gas-tight sparking chamber.** Frederick Edward Oldfield and Owen George Cowper, 43, Trinity-street, Southwark, London.

12852. **Improvements in electro-plating.** Richard Bruno Roxby, 53, Chancery-lane, London.

12853. **Improvements in or connected with the electro-plating of aluminium.** Richard Bruno Roxby, 53 Chancery-lane, London.

12875. **Improvements in and relating to electric arc lamps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

12876. **Improvements in and relating to alternating-current dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (Allgemeine Elektricitäts Ges., Germany. (Complete specification.)

JUNE 22.

12880. **Improvements in electric conductors.** Anson Gardner Betts, Troy Rensselaer County, New York, United States.

12899. **Improvements in dynamo-electric generators and motors.** Leonard Knight Clark, 128, Colmore-row, Birmingham.

12914. **Improvements in telegraphic receiving apparatus.** Stephen Dudley Field, 65, Chancery-lane, London. (Complete specification.)

12945. **Improvements in dynamos for railway train lighting.** Henry Leitner and Richard Norman Lucas, 4, South-street, Finsbury.

12947. **Improvements in or relating to the storage of electrically-transmitted energy.** Henry Wilson Fox, 322, High Holborn, London.

12953. **Improvements relating to safety devices for electrical apparatus.** Lorenz Kottmair and Rudolf Zwack, 7, Southampton-buildings, Chancery-lane, London. (Complete specification.)

12964. **Improvements in electric arc lamps.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.)

JUNE 23.

6987A. **Improvements in electric stop-motion mechanism for looms.** Joseph Botsford Whitney, 18, Fulham-place, Paddington, London. (Date applied for under Patents Rule 9, April 3, 1905.) (Complete specification.)

6987B. **Improvements in fallers for electric stop-motion mechanism for looms.** Joseph Botsford Whitney, 18, Fulham-place, Paddington, London. (Date applied for under Patents Rule 9, April 3, 1905. (Complete specification.)

12973. **An electrical timing apparatus for timing motorcars and for other analogous purposes.** James Martin Inglis, 37, West Nile-street, Glasgow.

12976. **Improvements in the methods of and means for the distribution of electricity to street lamps and the like.** George Wilkinson, Beech Mount, Harrogate.

12999. **Improvements in means for ensuring the continuity of movements derived from electric energy.** Arthur Booth Webber and the Standard Time Company, Limited, 22, Southampton-buildings, Chancery-lane, London.

13009. **Improvements in automatic signalling apparatus more especially for use in connection with electric traction systems.** Max Byng and William Charles Cloete Hawtayne, 71, Queen Victoria-street, London.

13025. **Improvements in electric arc lamps.** William Reginald Ridings, Westinghouse Patent Bureau, Westinghouse Building, Norfolk-street, Strand, London.

JUNE 24.

13062. **Improvements in or connected with insulators of electric railways, tramways, and the like.** Robert Naudin Tweedy, Toydene, Amblecote, Stourbridge, Worcestershire. (Complete specification.)

13063. **Improvements in or relating to electric clock and alarm systems.** Wilhelm Rausch and Hermann Gondolf, 30, Belvoir-street, Leicester. (Complete specification.)

13073. **Improvements in telephone and telegraph relays.** William Aitken, c/o The British Insulated Helsby Cables, Limited, Milton-road, Edge lane, Liverpool.

13084. **Improvements relating to controllers for single-phase induction motors.** Ray Philip Jackson, The Westinghouse Patent Bureau, Westinghouse Building, Norfolk-street, Strand, London. (Date applied for under Patents Act, 1901, June 30, 1904, being date of application in United States.) (Complete specification.)

13093. **Improvements in or relating to electric drills.** Alfred Julius Boult, 111, Hatton-garden, London. (William Obed Duntley, United States.) (Complete specification.)

13107. **Improvements in dynamo-electric machinery.** The Honourable Charles Algernon Parsons and Alfred Flint, 18, Southampton-buildings, Chancery-lane, London.

13108. **Improvements in dynamo-electric machinery.** The Honourable Charles Algernon Parsons, 18, Southampton-buildings, Chancery-lane, London.

Digitized by Google

**13112. Improvements in and relating to dynamo-electric machines.** The British Thomson-Houston Company, Limited, 83, Cannon-street, London. (The General Electric Company, United States.) (Complete specification.)

**13113. Improvements in holders for commutator brushes.** The Morgan Crucible Company, Limited, and Charles William Speirs, 4, South-street, Finsbury, London.

## COMPLETE SPECIFICATIONS ACCEPTED.

*To be published July 13.*

1904.

**6959. Filaments for electric incandescent lamps and method of manufacturing the same.** Levis. (General Electric Company.)

**16410. Electric measuring instruments.** British Thomson-Houston Company, Limited. (General Electric Company.)

**16619. Electric ignition apparatus for exploding gases in rotary or reciprocating engines.** Somerville.

**16853. Stopping-place indicators for electric tramcars and the like.** Wright.

**17000. Electromagnetic relays.** Tyer, Hollins, and Leake.

**17017. Electric motor-control systems.** British Thomson-Houston Company, Limited. (General Electric Company.)

**17021. Controllers for electric motors.** British Thomson-Houston Company, Limited. (General Electric Company.)

**17023. Electric switches.** British Thomson-Houston Company, Limited. (General Electric Company.)

**17024. Electric controllers for electric circuits.** British Thomson-Houston Company, Limited. (General Electric Company.)

**17632. Means for operating the points of electric tramways and the like, and also the overhead points or trolley switches and devices for actuating such operating means.** Norris.

**17705. Vaporisers.** British Thomson-Houston Company, Limited. (General Electric Company.)

**17803. Electrical measuring instruments.** Eversbed and Vignoles, Limited, and Eversbed.

**18054. Electric device for indicating the unauthorised opening of doors locks, window fastenings, and the like.** Levin.

**18173. Mercury and the like vapour electric apparatus.** Oarclan. (General Electric Company.)

**19061. Instruments for making calculations in regard to electric conductors and other problems.** Hincks.

**19917. Push buttons and the like for electric bells and similar services.** Harcourt.

**22647. Electrical resistances.** Moy and Bastie.

**23804. Insulators for high-veltage electric lines.** Soc. Ceramica Richard-Ginori. (Date applied for under International Convention, June 22, 1904.)

1905.

**410. Electrical hydro-pneumatic governor for marine engines.** Grasset.

**1552. Electric fans.** Fairweather. (Diehl Manufacturing Company.)

**1607. Alarm fuse for telephone exchanges.** Craft. (Date applied for under International Convention, Feb. 5, 1904.)

**2888. Electrical trolley heads with wire-finding apparatus attached.** Cherry and Olive.

**5232. Electric current circuit breakers.** Moy and Bastie.

**6066. Electric clocks.** Hope-Jones.

**7211. Electric clocks.** Campiche.

**7438. Method of securing the removable cover of a tumbler or like electrical switch.** Davies.

**8540. Electric induction meters.** Cie. anon. Continentale pour la Fabrication des compteurs à Gaz et autres Appareils. (Date applied for under International Convention, Feb. 16, 1905.)

**10853. Vapour electric apparatus.** Thomas. (Date applied for under International Convention, May 25, 1904.)

**10768. Receivers for wireless telegraphy.** Thompson. (Ges. für drahtlose Telegraphie m. b. H.)

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

### QUESTIONS.

753. Discuss the rules for determining the most economical current density of a one square inch cable, one mile long, insulated in a satisfactory manner, working at a pressure of 1,000 volts direct current, the duration of the maximum load being on an average five hours per day, cost per unit delivered to conductor 1d., and interest and depreciation on cable taken at 10 per cent. State which rule you think gives the best result.—S. A. H.

754. It is well known that the indicated horse-power of a triple-expansion engine can be varied by altering the cut-off of the intermediate-pressure or low-pressure valve, the high-pressure cut-off meanwhile remaining the same. I am not referring to extreme variations, when the engine almost ceases to be triple-expansion, but to slight alterations in the cut-offs, when the engine is doing equal work in each cylinder. Can anyone explain why this should be so?—J. P.

### ANSWERS.

*Question No.* 745.—A direct-current generator of 500 volts, for use on a three-wire system, is fitted with an automatic balancing arrangement, consisting of a choking coil fed, *via* slip-rings, from two points on the armature windings, the middle point of the choking coil being connected to the neutral 'bus bar. Can you give the theory of its action in balancing the pressure of the two sides of the network?

*Answer to No.* 745 (*awarded 7s. 6d.*).—To simplify matters as far as possible, consider the case of a simple ring armature revolving in a two-pole field. Figs. 1 and 2 represent this, $B_1$ and $B_2$ being the diagrammatic representation of the two commutator brushes, and $s_1$ and $s_2$ the brushes on two slip-rings. These slip-rings are connected to two opposite points of the armature winding, and from them a single-phase alternating current can be collected, the virtual voltage being about four-fifths of the continuous-current voltage (with a pole arc of 50 per cent.). The maximum alternating-current voltage corresponds to the position in Fig. 1 when the instantaneous voltage between the slip-rings is

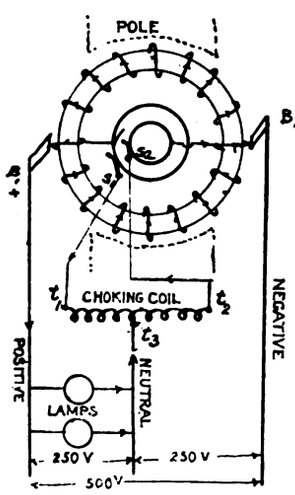

FIG. 1.

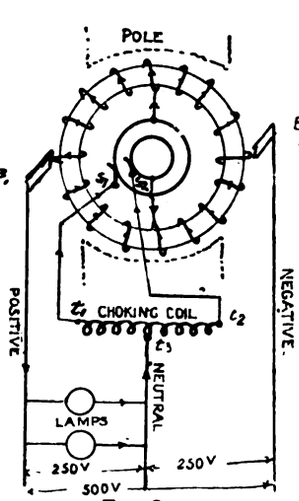

FIG. 2.

equal to the voltage between the continuous-current brushes, $B_1$ and $B_2$. In Fig. 2 the alternating pressure is now zero, corresponding to a quarter of a cycle's advance. One complete revolution of the armature corresponds to one complete cycle of the alternating current. If the two slip-rings are connected to a suitably designed choking coil, under normal conditions, an alternating magnetising current will flow in this coil. It is found, however, that if the centre point of the coil is connected to a terminal, $t_3$, a continuous current will flow between this terminal and either continuous-current brush, $B_1$ or $B_2$, and that the voltage will be half that between the continuous-current brushes, $B_1$ and $B_2$. The combination can thus be used to run a three-wire continuous-current distribution system, by connecting the neutral to the terminal, $t_3$, of the choking coil.

It was shown above that the voltage between the slip-rings varies from a maximum (in Fig. 1), when it is equal to the continuous-current voltage, to zero a quarter of a revolution later. A quarter of a revolution later still it will be at a negative maximum, and so on through the cycle. Now this voltage is what is applied to the choking-coil terminals, and it is obvious that the voltage between $t_3$ (the centre terminal) and $t_1$ or $t_2$ is always half that between $t_1$ and $t_2$; in other words, the potential of the point $t_3$ is always midway between the two potentials of the points $t_1$ and $t_2$—that is, midway between the potentials of the two slip-rings. At one moment (as in Fig. 1) the potential difference between $t_1$ and $t_2$ is equal to the potential difference between the continuous-current brushes—say 500 volts—and the point $t_3$ is at a potential halfway between these brushes. A little later (as in Fig. 2) the voltage at the terminals of the choking coil is zero, each end being connected to points on the winding situated at that instant symmetrically in the field. The point $t_3$ is at a potential midway between $t_1$ and $t_2$ (in this case the three potentials are all the same, and equal to zero), so that it is at a potential halfway between the brushes, $B_1$ and $B_2$. It can easily be seen that since the connections to the two slip-rings, $s_1$ and $s_2$, are symmetrically placed with regard to the armature and the continuous-current brushes, a point at a potential halfway between that of $s_1$ and $s_2$ is also halfway between that of $B_1$ and $B_2$ (the continuous-current brushes). The terminal, $t_3$, of the choking coil is such a point, and is, in fact, at all instants at what may be termed the electrical centre of the system. It is thus clear that the voltage between either continuous-current brush and $t_3$ is constant and equal to half that between the two continuous-current brushes.

It is interesting to follow out the course of the current. In Fig. 1, where two out-of-balance lamps are shown on one side of the three-wire system, the current comes out from the + brush through the lamps to the terminal $t_3$. Here it joins with the alternating magnetising current flowing, and goes *via* $t_2$ and $s_2$ to the armature, joining it just under the negative continuous-current brush. A reference to the diagram clearly shows that at this instant the voltage at the terminals of the lamps is half that of the brushes, $B_1$ and $B_2$. In Fig. 2 the current, after reaching $t_3$, will divide, part going *via* $t_1$ and $s_1$ and part *via* $t_2$ and $s_2$ to the armature, entering it at symmetrically placed points; and, again, it is obvious that the voltage at the lamp terminals is half that between the brushes, $B_1$ and $B_2$.

The above method of balancing can be used with three slip-rings connected to points 120deg. apart and giving three-phase current, and in practice this is the arrangement generally adopted. The choking coil has then three limbs star-connected, and the terminal $t_3$ is at the centre of the star. The coil has to be designed to stand the applied voltage, and large enough to carry the out-of-balance current expected without overheating. The arrangement has the advantage that no moving machinery save the main generator is required to balance the system, and in a properly-designed coil the losses are quite as small as those in a balancer.—W. W. W.

*Answer to No.* 745 (*awarded 7s. 6d.*).—This method of balancing has, I believe, only come up quite lately, and, that being so, it is not easy to hear results as to its working, but in one station I know where they have it they do not use it, but prefer the usual balancer.

The idea is this. Points are taken at 180deg. from each other round an armature, in which case it will readily be seen that there will be as many tappings as there are poles; these are taken down to two slip-rings, every alternate tapping being connected to the same slip-ring. Connections are then taken from brushes pressing on these slip-rings, through switches to the two opposite ends of the winding of a choking coil. The middle point of the winding of this coil is then connected through a switch to the neutral 'bus bar on the switchboard. The winding on the choker must be designed to be heavy enough to carry

Digitized by Google

about the full out-of-balance current continuously when on load.

Fig. 1 is a diagram which should explain the above and make matters clear. In this N and S are two poles of a two-pole dynamo, between which the armature revolves; + and − are the two brushes on the commutator. A and B are the two conductors 180deg. apart, from which tappings are taken to the two slip-rings, from which it is collected by the brushes C and D. From C and D it passes through two switches, Sw, to the two terminals of the choking coil, F, from the middle point, E, on the winding of which there is a connection through a switch to the neutral 'bus bar. A little careful consideration of this diagram will reveal the fact that when the machine is running there will be an alternating current flowing between A and B by way of the slip-rings, brushes, and choking coil. This alternating current will have a frequency of P $n$ cycles per second, where P represents the number of pairs of poles and $n$ represents the number of revolutions of the armature per second. Now, in the case in point A and B are removed from the + and − brushes on the commutator by an equal distance, and, being similarly placed, the differences of potential between A and the − brush and B and the + brush will be equal; this is equivalent to having the same difference of potential between each end of the choking coil and the two outer 'bus bars. Now, as E is

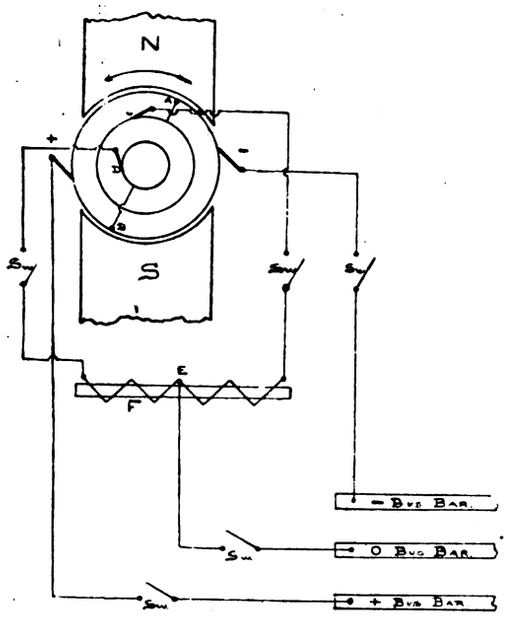

FIG. 1.

midway between the two ends of this choker, and these two halves are similar, the differences of potential between E and each end must be an equal amount, hence the voltage between E and each outer must be equal, and in this case that will be 250 volts, and this being connected to the neutral 'bus bar, we obtain the result of having 500 volts across the outers and 250 volts between the neutral and each outer. It will then be seen that for whatever position the wires, A and B, may be at any instant in a revolution of the armature, still there will be 250 volts difference of potential between the point E and the two outers, and this point E will always be 250 volts below the + 'bus bar and 250 volts above the − 'bus bar. The direction of the current in the choking coil will be determined by the position of the two wires, A and B, with reference to the + brush, as the current will always flow in the choker from the wire which is nearest to the + brush to the one which is nearest the − brush. Now, having shown that E will always be 250 volts negative to the + brush and 250 volts positive to the − brush, I will next proceed to explain the action of this choking coil when the machine is connected up to a three-wire network in which the load is not equally balanced on each side, but in which there is an out-of-balance current flowing in the middle wire. Let us assume a pure lighting load with 1,000 lamps on the + side and 1,200 lamps on the − side (all of the same candle-power and efficiency), and further let us assume that the resistance of a 16-c.p. lamp for use on this voltage is 1,000 ohms. Therefore, the total resistance of the + side will be $\frac{1,000}{1,000}$ = 1 ohm, neglecting resistance of the mains, etc. Likewise the resistance of the negative side will be $\frac{1,000}{1,200}$ = ·83 ohm. In the above I have neglected to take into account the fact that owing to the sides being out of balance there will be a higher voltage on the + side than the − side, and hence the resistance of the filaments on this high side will be greater than that on the low side, owing to the increase of resistance with the rise of temperature of the filament. Adding together these two resistances we obtain as a result 1 + ·83 = 1·83ohms resistance from outer to outer. Now, by Ohm's law we shall get a current of $\frac{500}{1·83}$ = 273·2 amperes flowing in our outers. Now, also by Ohm's law, it will be seen that it takes 273·2 × 1 = 273·2 volts to drive the 273·2 amperes through a resistance of 1 ohm—*i.e.*, the + side, and also it will take 273·2 × ·83 = 226·7 volts to drive 273·2 amperes through ·83 ohms—*i.e.*, the − side. The sum of these two voltages 273·2 and 226·7 gives us, of course, 500, which is the voltage across the outers of the supply. This means that, neglecting any balancing, with the load as indicated, the voltages on the two sides of supply will be respectively 273 volts on the positive side and 227 volts on the negative side, the result being that the lamps on the + side will burn very bright, and those on the − side will burn dim.

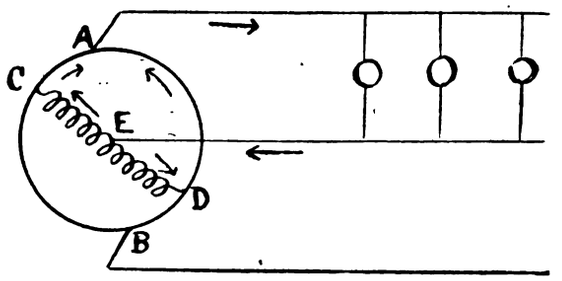
Now, let us next ascertain what would be the out-of-balance current in the neutral 'bus bar if, by some means or other, the voltages on each side were the same—*i.e.*, both 250 volts. By Ohm's law we now have a current of $\frac{250}{1}$ = 250 amperes on the + side, and a current of $\frac{250}{·83}$ = 300 amperes on the − side, so the result is that we have an out-of-balance current of 50 amperes flowing in the neutral. If we now look back over what we have done, we shall see that if the choking coil has its middle point connected to the neutral 'bus bar it will have a balancing effect, and will endeavour to keep the voltages on each side equal—*i.e.*, 250 volts—whereas, owing to the way the load is distributed, the voltage across the + and neutral 'bus bars will tend to be 273 volts, and that across the neutral and − 227 *volts*. Now, considering the − side, this is surely akin to paralleling 250 volts with 227, hence a considerable amount of the current for the negative side would come from the armature *viâ* the choking coil. This being so, it will not be necessary for the total current to flow through the + side, and so the voltage on that side will drop, and in the end we should obtain the required result of 250 volts either side with the out-of-balance current of 50 amperes being supplied by the choking coil arrangement. This may at first sight appear to be impossible, but, nevertheless, it is the case, and so I trust it will become plain that a choker connected thus can and does do the balancing. Of course, it will be understood that the less resistance in the winding of the choking coil the better, or else we should get a drop of potential in the choker itself due to it carrying the out-of-balance current. It will also be seen that as the armature revolves, the out-of-balance current will pass first through one half of the choker and then through the other, but always in the same direction with reference to the neutral 'bus bar according as to which side of the system is the heavier loaded, and the number of times it changes from one half to the other per second will be 2 P $n$, where P = the number of pairs of poles and $n$ = the number of revolutions per second. The object of making it a choking coil—*i.e.*, a coil possessing little resistance but considerable self-induction—is obviously to prevent a large wasteful current flowing from one slip-ring *viâ* the coil to the other, as this current would be alternating, and so the self-induction keeps this down, whereas it will let a continuous current flow through it, which is what we require for our out of balance, and even if the current does rise slowly in one half, when changing from one half to the other, still it will fall just as slowly in the other half, and the net result will be the same. At the times when the two wires from which the two tappings are taken are midway between the + and − brushes there will be no difference of potential between them, but still the middle point of the choking coil will be

Digitized by Google

250 volts above and below the – and + 'bus-bar potentials respectively, and then, but for the lag of the currents in the two halves in growing and dying down, each half would take an equal share of the out-of-balance current. I believe this method of balancing has been tried by taking three points on the winding of an armature 120deg. apart, and then joining these to one common point through three similar choking coils (as in three-phase star connections), and so creating an artificial neutral and connecting this to the neutral 'bus bar through a switch.

I think from the above explanation it will be quite possible to understand this method of balancing, and a little thought will clearly indicate the directions the currents are flowing in the different wires under the various conditions, and so it is hardly necessary for me to do so now, as similar reasoning will show how an out-of-balance current on the positive side would be dealt with.—E. R. ALEXANDER.

*Answer to No.* 745 (*awarded* 5*s.*).—In the figure the arrangement described in the question is shown diagrammatically for a two-pole machine. The E M.F. between the brushes marked A and B remains constant at 500 volts. The E M.F. between the points C and D, which are connected by means of the slip-rings to the terminals of the choking coil, is an alternating one; it alternates with a frequency equal to the revolutions of the armature. This alternating E M.F. sends a small magnetising current through the choking coil which has a high self-induction. When C coincides with A and D with B, the E.M F. between C and D is, of course, 500 volts. In this position there are no armature coils between A and C, but between C and B there are half the total number of armature coils by each of the two paths; as C moves away from A and towards B, its potential changes in a corresponding manner,



so that the potential of C differs increasingly from the potential of A, and approaches the potential of B, until the point C coincides with the brush B, when, of course, B and C are at the same potential In the meantime the potential at D has been changing from the potential of B to the potential of A in an exactly similar manner, hence the potential between the terminals of the choking coil is not only an alternating one, but by the symmetry of the arrangement, the P.D. between A and C is at every instant equal to the P.D. between D and B. Now, the choking coil is really an auto-transformer, and the E M.F. of each turn being the same, since each has the same change of magnetic flux through it, therefore the middle point, E, is at a potential half-way between the potentials of C and D, and since the P.D. between A and C is equal to the P.D. between D and B, therefore the potential of E is always half-way between the potentials of the two brushes, and being connected to the neutral 'bus bar maintains the middle wire at the desired potential.

Consider an out of-balance current returning on the middle wire. As it is only the out-of-balance current that we are concerned with, we may neglect the balanced portion and regard the system as being loaded on one side only, as in sketch. The current we are considering all flows through one brush and returns by the middle wire to the point E. At E this current divides into two equal parts, one flowing through C and the other through D to A, where they again unite. The two equal currents in opposite directions in the two halves of the winding of the choking coil have no resultant magnetising effect on the iron core; their effects neutralise each other. Moreover, these currents are continuous, and hence they are not in any degree hindered by any choking action. The resistance of the two paths through the armature are in general not equal, and they are also varying continuously, but the armature resistance and the resistance of the choking coil, if properly designed, are both small, and the volts lost in ohmic drop will be negligible.

Perhaps another way of explaining the working of the arrangement would be to first of all suppose the choking coil replaced by a resistance, which would allow an alternating current to pass. This current would be in phase with the E.M.F. between C and D, and the middle point of the resistance would be at the correct potential for the middle wire, but if connected to it, the moment there was any out-of-balance current the available potential on the heavier-loaded side would decrease, on account of the ohmic drop. By the simple device of replacing the resistance with the choking coil, the resistance of whose winding may be very small indeed, the ohmic drop may be made negligible, while at the same time the energy wasted is also practically negligible, as there is only a small magnetising current flowing between C and D, and even this is largely wattless.—SUPERHEAT.

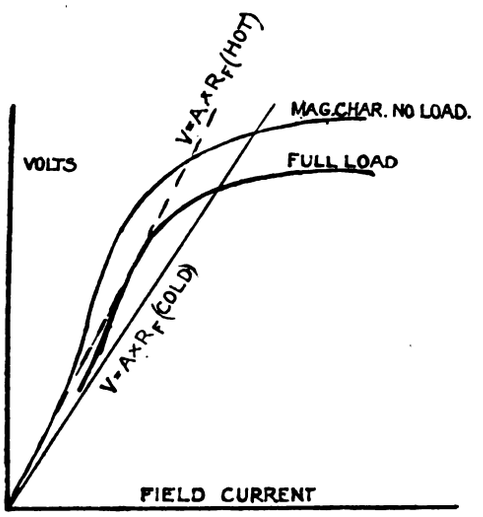
*Question No.* 746.—A 300-kw. Ferranti alternator (2,100 volts, 50 cycles, single-phase) is excited by a shunt-wound Elwell-Parker machine rated at 100 volts and 60 amperes, rope-driven from the main shaft. The exciting current varies from 40 to 60 amperes. Several times during the last 18 months this machine has dropped her exciting current under various load conditions, picking it up again after a short interval on one or two occasions. Careful examination for loose connections, slipping of the ropes, earths, or shorts on the exciter connections has failed to reveal any fault which would account for this behaviour. Moreover, the machine has invariably run satisfactorily on the next shift. The writer would be glad of an explanation of this phenomenon.

*Answer to No.* 746 (*awarded* 7*s.* 6*d.*).—The failure of the exciting current is most probably due to the resistance of the field winding of the direct-current machine being too near the critical value. For every shunt dynamo, at a definite speed, there is a certain critical value of the resistance of the field winding, which, if exceeded, will prevent the machine from exciting itself. This value can be determined as follows: Separately excite the field from cells, and for various values of the exciting current observe the E.M.F. at the brushes while the machine is running at the proper speed; plot the connection thus obtained on squared paper with field current for abscissæ and terminal volts for ordinates. The resulting curve is known as the magnetising characteristic. If the machine is delivering current the voltage at the brushes is less than the voltage on open circuit, by the ohmic drop in the armature, and also on account of a weakening of the field strength by armature reaction. If the voltage required to send the current through the field winding is less than the brush voltage, then the field current will be greater than necessary for this particular voltage, which will, therefore, rise until the required voltage and the available voltage are the same. If, on the other hand, the voltage necessary to maintain the field current is greater than that at the brushes, of course the field current is not maintained, and will decrease, with consequent drop of terminal volts, until either the available volts and required volts are equal once more, or the machine has lost all its volts. (This latter alternative is only another way of saying that the required and available volts are equal when each is equal to zero.)

The requisite value for the field voltage is got by simply multiplying the field current by the resistance of the winding. It is possible to represent it by a straight line on the same piece of paper as that on which the magnetising characteristic is drawn. Appended is a sketch in which are shown the sort of curves one may expect for a shunt dynamo running at a fixed speed, connecting brush voltage with field current when the machine is unloaded, and also when fully loaded. The straight line, undotted, gives the connection between required voltage and field current when the field winding is cold, say. The height of this curve is everywhere equal to the field current multiplied by the field resistance when cold. The points where this line cuts the first two curves gives the terminal voltage of the machine at no load and full load respectively for the particular speed at which it is running. Suppose that when the shunt has got warm by a long run, the connection between required voltage and current in the field can be represented by the dotted line in the sketch. As this line is everywhere higher than the brush voltage for the fully-loaded

Digitized by Google

machine, whatever the strength of the field current, the excitation will disappear, although if the load be switched off the machine may re-excite, since then the brush voltage is up to a certain point higher than what is required to maintain the field current. This point where the two curves cross gives the value to which the volts will rise under these conditions. It is probably only when the machine has been running for a considerable time that its excitation fails. If this is so, it tends to confirm the explanation here given, and apparently a short rest allows the copper to cool sufficiently for re-excitation. Since the



excitation fails only occasionally, the resistance must be, as a rule, within the critical value, and a very slight movement of the brushes from the position of maximum E.M.F., or a very small amount of belt slipping, may account for the failure. Probably the best way of preventing the occurrence in future would be to so alter one of the pulleys that the speed of the dynamo will be increased.—SUPERHEAT.

*Answer to No.* 746 (*awarded* 7*s.* 6*d.*).—Assuming that the examination made by "W. H. H." for loose connections and faults has been thorough, we must look into the design of the exciter for an explanation of this phenomenon. Let us assume that the connections of exciter to alternator are as shown in Fig. 1, and also that as the exciter is a shunt-wound machine its characteristic curve would be as shown

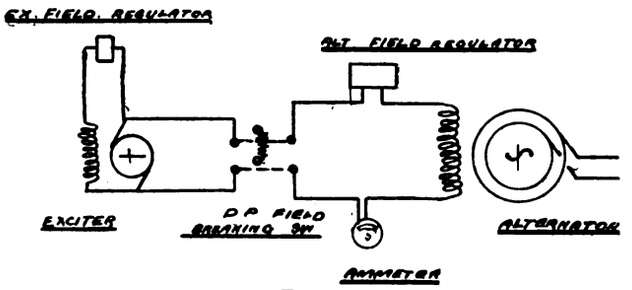


FIG. 1

in Fig. 2. It will be seen from this curve that if the current taken from the exciter is pushed too high, its volts will drop, and, therefore, its field will gradually get weaker, and it will cease to generate any current. With an exciter rated for 60 amperes this critical point should not be reached until there is a considerable overload, but the machine may be closely rated. Seeing, however, that we have a regulating resistance in both exciter field and alternator field, it would be possible, if the resistance in exciter field was high enough, to get the condition of affairs as set forth in the question at any load on the exciter. I think that if field of exciter was kept fully excited, regulating alternator field by resistance in its circuit, that the phenomenon would not occur.

The objection to this method is, of course, the waste of energy dissipated in the resistance. Suppose, for example, that all, or nearly all, the resistance was in exciter field, the exciter running, say, on about 40 amperes, there also being some resistance in alternator field. If there was now an increase of load on the alternator, resistance would most likely be cut out of its field to bring up its volts. Now, as the exciter is not working with its full field strength, the critical point on its curve would soon be reached, as this curve is only true for a case with no resistance in circuit, and would be different from the curve shown if resistance was in exciter field. This is very likely what happens. An

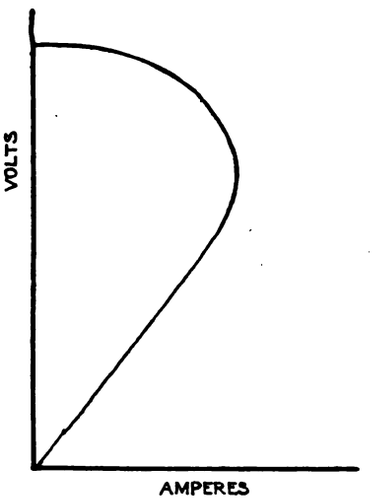

FIG. 2.

increase in load, which would bring down speed somewhat on engine, would assist in bringing about this state of affairs. The remedy is to either work on the resistance in alternator field, as suggested, or to put a few series turns on exciter field, thus compounding it.—J. H. THOMAS.

*Answer to No.* 746 (*awarded* 5*s.*).—The writer has found from his experience of Ferranti single-phase alternators that considerable margin in exciter voltage has been allowed for contingencies over and above what may be required to excite the alternator on its maximum load, which may be 25 per cent. or more overload. This margin, together with the difference in voltage required to send 40 amperes through the field on open circuit, as against 60 amperes on full load, may cause the exciter to be working at as low a voltage as 55 or 60 volts. It should be noticed that at this low voltage a current is drawn from the exciter approaching that equal to full load, whilst the exciter is considerably weakened. However stable the exciter field may be at its normal voltage of 100, it is far from being so at about 50 volts and a heavy armature current. The exciter is more than likely to be working well below the knee of the magnetisation curve. The brushes on exciters are very rarely moved whatever load is on the exciter unless sparking takes place. The brushes are consequently likely to be left in the position for top load, and therefore unfavourably placed for low load on the exciter, and thus assist greatly to demagnetise by additional back ampere-turns on the armature.

Under these conditions, therefore, it requires only a slight reduction in the speed of the engine due to a sudden increase in load (and before the governor has time to correct it) for the exciter to lose its field. The exciter would, under these circumstances, be able to pick up its field, which it would do more or less quickly, according to the conditions prevailing, on normal speed being resumed. Multipolar exciters which have the commutator bars moved round relative to the neutral position of the magnetic field have also given trouble, owing to the reduction in voltage caused by the faulty position of the brushes until their true position was ascertained. If attention were paid to the position of the brushes, and these moved to suit the load, some of the trouble might be eliminated.—W. W.

[Other replies to Question No. 746 will be given in our next issue.—ED. *E. E.*]

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

755. An 80ft. brick chimney stack is obliged to be reduced in height by 20ft. To what extent could the loss in draught be remedied by taking the exhaust pipe up the inside of the chimney? At what height should the exhaust pipe enter, and at what distance from the top should it terminate to give the best results?—A.

756. A 160-h.p., 400-volt, shunt-wound motor, eight-pole type, is started up for the first time on no load, by means of a tramway-type controller having six contacts for the armature resistance. The motor runs well on the first and second contact, but when the controller is moved on to the third contact one of the top set of brushes commences to spark intermittently, and then suddenly there is a vivid electrical discharge between two neighbouring brushes, which are about 9in. apart, and the circuit breakers are thrown out. Various positions of the brushes are tried in close proximity to the sparkless position, but with the same result. Explain the cause and remedy of the above occurrence.—J. S. P.

### ANSWERS.

*Question No.* 746.—A 300-kw. Ferranti alternator (2,100 volts, 50 cycles, single-phase) is excited by a shunt-wound Elwell-Parker machine rated at 100 volts and 60 amperes, rope-driven from the main shaft. The exciting current varies from 40 to 60 amperes. Several times during the last 18 months this machine has dropped her exciting current under various load conditions, picking it up again after a short interval on one or two occasions. Careful examination for loose connections, slipping of the ropes, earths, or shorts on the exciter connections has failed to reveal any fault which would account for this behaviour. Moreover, the machine has invariably run satisfactorily on the next shift. The writer would be glad of an explanation of this phenomenon.

*Answer to No.* 746 (*awarded* 5*s.*).—Overload may cause a shunt dynamo to lose its field, but if, as per data in query, this occurs at various loads, we must seek for some other explanation. With regard to non-slipping of ropes, it would be advisable to take the revolutions of the dynamo by means of a counter; it may be just possible that the machine is running at about its critical speed. The adjustable resistance in the shunt winding should be carefully overhauled; there may be points where bad contacts are made; vibration from one or many causes may cause a break in the circuit. Look to the commutator and brushes. The writer some time ago had a somewhat similar trouble with a shunt dynamo fitted with carbon brushes. It was found necessary to frequently polish the commutator, and by means of emery cloth reface the carbon brushes where they bedded on the commutator. Unless this was done several volts were lost between commutator and carbons. The machine described in query may be excited so near the critical point on its characteristic that the loss of a few volts may make all the difference required to reach the position of instability. If, after careful examination for bad contacts, etc., the trouble should still continue, try copper brushes. As a last resource, alter the magnet winding so that the field is at a higher point of saturation. M. M.

*Question No.* 747.—How is it possible to predetermine, with anything like accuracy, the point at which a "synchronous" motor will drop out of step?

*Best Answer to No* 747 (*awarded* 10*s.*).—It is possible to determine graphically the maximum load of a synchronous motor, but although the machine will fall out of step when loaded to this amount, cases more generally arise where, because of what is known as phase swinging or the periodic variation of the speed just above and just below perfect synchronism, a motor will slow up long before the maximum has been applied. In fact, as this phase swing is more pronounced at light loads, the motion is often then more unstable than when the motor is normally loaded. The conditions which determine the degree of stability of a machine at ordinary loads are very complicated, and depend to a very large extent on what other machines, both generators and motors, are on the circuit, and also on the nature of its own load; but as the relation between the maximum load and the normal load is a good guide to the running qualities of any particular machine, the problem may be taken as satisfactorily solved if we develop a means for determining this maximum load It may here be remarked

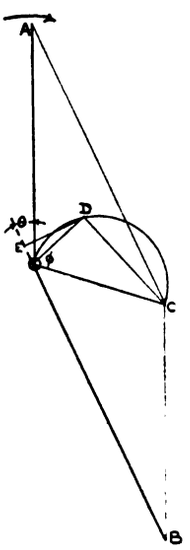

FIG. 1.

that the maximum load is different for different excitations, but the diagram to be given is applicable to all cases. In Fig. 1 we have the diagram as generally given for the synchronous motor. O A represents the applied E.M.F. of the motor and O B the generated E.M.F., which depends in value upon the excitation, and in general lags more than half a period by an angle $\theta$. Compounding O A and O B we get O C as the voltage, which is not balanced, and which, therefore, provides current to drive the machine. If the current lags by an angle $\phi$, O D will represent the current and therefore also the component of O C used in overcoming resistance, and D C corresponds to the drop in impedance which is determined in the usual way from the short-circuit characteristic. The output under these conditions is given by the rectangular component O E of the current O D upon the line of the generated voltage. To alter the value of the output O E, the angle $\theta$ varies, the excitation and therefore O B remaining constant, so that the rectangular component of the current becomes more or less as required. To proceed further with the problem it is advisable to alter the manner of the diagram as it is usually given in Fig. 1 to that as it is now given in Fig. 2. O A and O B are applied and generated E.M.F. as before, and with the given value of $\theta$, B C gives the unbalanced voltage. This, again, is split up into B D, the ohmic drop,

Digitized by Google

and therefore also corresponding to the current and D C, the reactance drop. B E then corresponds to O E, the power component of the current.

If, now, another value of $\theta$ is taken, we have a new position of C at $C_1$. Going through the construction again, we obtain B $E_1$ as a new value of the output, larger than before. If we tried another point, $C_2$, further still round the circle, we could find another position for $E_2$ which would give a smaller power than B E. There is therefore

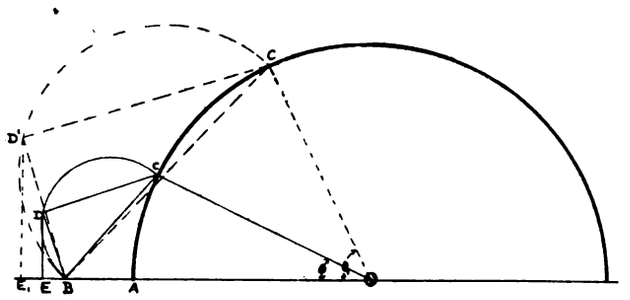

FIG. 2.

a position of C for which the power B E is a maximum—*i.e.*, the position of C which will give the corresponding point D its farthest position to the left. The construction for this is shown in Fig. 3. O, A, and B are as before. Now, consider the case of the maximum and minimum values of $\theta$—*i.e.*, 0deg. and 180deg. The circles, such as B, D, C in Fig. 2, for these values are B $D_0$, A, and B $D_{180}$ X respectively, and splitting up B A and B X in the same ratio as before, we have the points $D_0$ and $D_{180}$ correspond-

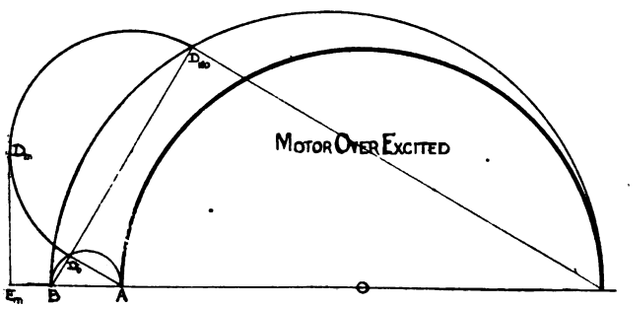

FIG. 3.

ing to these extreme conditions. The locus of D for all the intervening values of $\theta$ *is then given by the semicircle* $D_0$ $D_m$ $D_{180}$ *on* $D_0$ $D_{180}$. The point on this semicircle which is farthest to the left, is evidently that from which the tangent drawn is also perpendicular to O A B produced. B $E_m$ corresponds, therefore, to the largest output at this degree of over-excitation. The actual value of this output in watts is obtained by multiplying together O B and B E translated to volts, and then

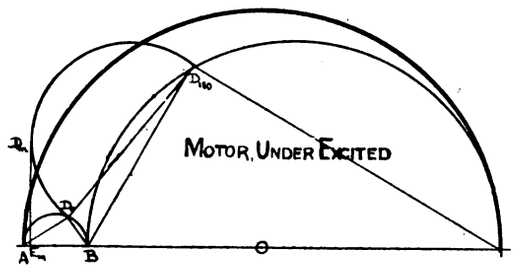

FIG. 4.

dividing by the resistance of the armature. The same construction holds for the cases of under excitation and normal excitation, that for the former being given in Fig. 4, where the letters mean the same as before. The case for normal excitation, and perhaps the most important, is shown in Fig. 5, the diagram becoming very much simplified owing to the points A, B, and $D_0$ coming into coincidence. It must be remarked that for the sake of simplicity the diagrams have been drawn somewhat out of proportion In an actual case, the synchronous impedance is many times greater than the resistance, and the triangle O D C in Fig. 1 becomes very acute at C. This makes the angle at X (Fig. 5) also acute, and in some cases it becomes impossible to draw the diagram with anything like accuracy, for A $D_{180}$ becomes so very small. In such a case it becomes very nearly perpendicular to X A, in which case the maximum output, B $E_m$, becomes equal in length to half A $D_{180}$. The maximum output can in such a case be calculated from the resulting simple expression,

$$\frac{E^2 \times n}{R \times I \times 2},$$

where E = the applied E.M.F.;
R = resistance per phase;
I = synchronous impedance; and
$n$ = number of phases.

As an example of this we may take the machine given by Mr. Eborall in his Howard lectures (see *Electrician*, xlviii., p. 275). The machine was three phase, 760 kw., 94 revolutions per minute, 50 ⁓, 2,200 volts. The resistance of armature per phase was given as 0·13 ohm, and the synchronous impedance calculated from the short-circuit test was about 3·0 for the higher currents.

The maximum capacity was, therefore,

$$\left(\frac{2{,}200}{1{\cdot}73}\right)^2 \times \frac{3}{3{\cdot}0 \times 0{\cdot}13 \times 2} \text{ watts}$$
$$= 6{,}100 \text{ kw.}$$

or nearly nine times the normal working value. It would, of course, be impossible to continuously load such a machine up to this amount; but in swing out of step from a normal load, this represents the maximum amount of power which

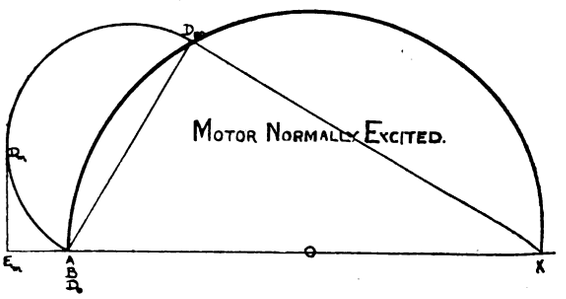

FIG. 5.

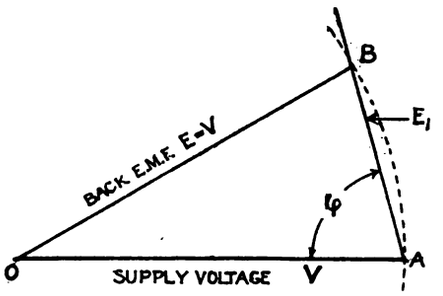
would be momentarily exerted to bring the machine back into step, and it is, therefore, not surprising that when swinging and only lightly loaded this large amount of power may do more harm than good in bringing the machine back to perfect synchronism.—H. W. T.

*Answer to No.* 747 (*awarded* 7*s.* 6*d.*).—The dropping out of step of a synchronous motor may be due to various causes. The first and simplest to deal with is the increase of load. It is well known that a synchronous motor can only absorb a determined amount of power. If the load, added to the losses in the machine, exceeds this power, the motor, instead of slowing down like a direct-current motor, refuses to do the work and fall out of step. But this maximum power which the motor can take from the mains must only be considered as a limit, which cannot be attained in practice for the following reason. When the load varies, the motor takes a certain time to adapt itself to the new conditions: it oscillates about the position of stable running, and if these oscillations are too great the motor will fall out of step. The amplitude of these oscillations depends on the difference of load put on the motor, and also on the suddenness of the change. Thus, if the motor is very lightly loaded and rapidly overloaded, it will fall out of step, although it would be able to bear a greater load if this was put on slowly. This shows us that it is not possible to tell exactly at what point the motor will fall out of step, except if the load was always altered in the same way. But there are other reasons more difficult to determine. A motor can fall out of step without any variation in the load. This may be due to irregularity of the supply current, very often caused by bad governing of the generating engines.

Digitized by Google

Particulars of the working of those engines would have to be known to tell what their influence on the synchronous motors is, and even then great accuracy could not be obtained. Disturbances are sometimes caused by the sticking of governors, and such cases would be impossible to determine. These oscillations, known as surging or hunting, can be considerably reduced by the use of damping coils (Leblanc amortisseurs).

Lastly, there is another reason for a motor to fall out of step; this is variation in the exciting current. By varying the excitation the driving torque is altered, and this gives rise to oscillations which may become dangerous. If we observe that the three causes mentioned—*i.e.*, increase of load, irregularity of supply current, variation in the exciting current—may act at the same time, this makes it still more difficult to determine the resulting effect due to their various combinations. To sum up, we may say that it is not possible to determine with exactitude the point at which a synchronous motor will fall out of step. All we can do is to determine the maximum power which the motor can take from the mains. This will give us the point at which the motor will fall out of step in the best conditions. This power can be obtained approximately in the following way: By varying the excitation, the current, C, flowing in the



armature can be brought into phase with the supply voltage, V. The power will then be a maximum, and the back E.M.F. of the motor, E, will practically be equal to V.

$$P = V C.$$

V is known, and C can be obtained as follows: Calling $E_1$ the resulting E M.F. produced by V and E, then

$$C = \frac{E_1}{\sqrt{R^2 + (2\pi n L)^2}}$$

R = armature resistance;
$n$ = cycles per second;
L = self-induction of armature.

$$P = \frac{V E_1}{\sqrt{R^2 + (2\pi n L)^2}} \quad . \quad . \quad . \quad . \quad (1)$$

The difference of phase between C and $E_1$ is given by

$$\cos \phi = \frac{R}{\sqrt{R^2 + (2\pi n L)^2}}.$$

Draw O A = V and A B, making an angle $\phi$ with O A. Cut A B with circle of radius E = V, and centre O. A B will then be equal to $E_1$, and P can be obtained from equation (1). ALTERNATOR.

*Question No.* 748.—Where several boilers are working together, is it common practice to fit isolating non-return valves instead of ordinary stop valves? State the advantages of doing so. Is there an automatic valve on the market which shuts off the steam supply when a pipe bursts? If so, describe it.

*Best Answer to No.* 748 (*awarded* 10*s*.).—It is now considered essential to safety to fit isolating valves, as well as stop valves, to each boiler in all cases where more than one boiler is working on the same steam main. Assuming several boilers feeding into one main and an accident occurring to one of the boilers—it may be a tube burst, a big leak in a seam, or the like—it is evident that considerable risk will attend any attempt to close the stop valve, especially if the fault be near the valve. The result may be that the other boilers working on the main discharge through the faulty boiler, and, so to speak, intensify the trouble. An isolating valve on each boiler localises the fault in and isolates the defective boiler, allowing the others to work without interruption. Where a boiler has been emptied for cleaning or inspection purposes, an isolating valve prevents the accidental turning on of steam from other boilers through the stop valve being opened or left open. An isolating valve also tends to the regulation of the equal firing of boilers, for if any one boiler falls below its proper pressure, the valve closes and the gauge shows the true boiler pressure. Of course, if only a stop valve be fitted, each gauge registers the steam-main's pressure. It is common practice to combine the stop and isolating valves, and many of the best valvemakers supply these. If, in addition to above, the valve is capable of closing automatically in either direction, so that in case of a steam-pipe bursting, or any other like accident happening outside the boilers, so to speak, the boilers are shut off from the mains, a further great safeguard is introduced.

There are several automatic valves on the market which shut off the steam supply when a pipe bursts, and one which gives excellent results is here described; it combines also the above features. Of course, it is an essential that the valve closes automatically in either direction, in case of a boiler accident shutting off steam from other boilers, and in case of steam main's accident shutting off the boiler steam supply. In Fig. 1 one type of the valve in question is

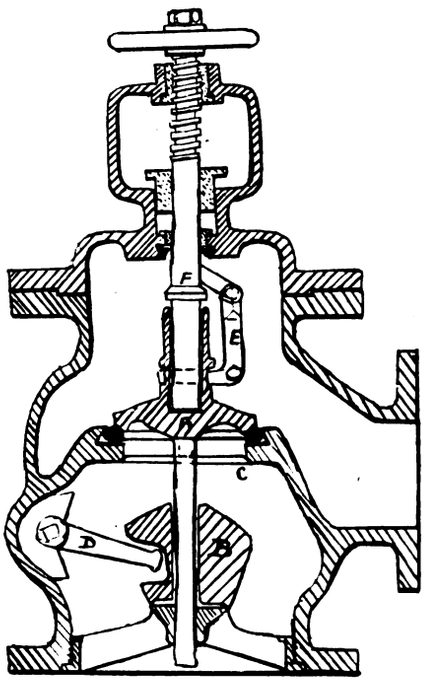


FIG. 1.

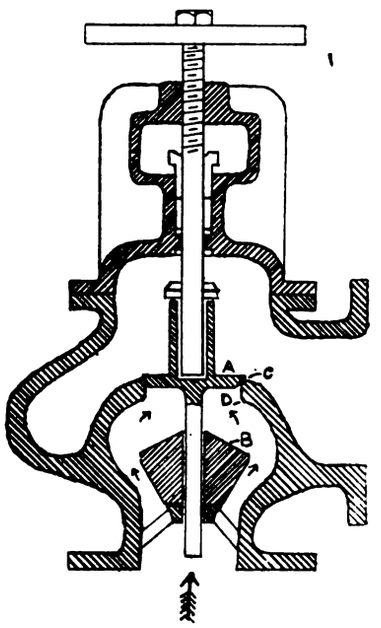
shown, and it will be seen that the valve is a combined stop and isolating valve. There are two valves, A and B, the upper and lower, both being loose on the spindle. When A is screwed down it acts as an ordinary stop valve, when the spindle is raised the valve is free, and the pressure on both sides being equal, is opened by the flow of steam from the boiler. In case of accident to the boiler, A, being loose on the spindle, acts as a non-return valve, and closes, preventing steam from other boilers passing. The lower valve, B, acts in the opposite direction, and under normal conditions is kept in position by its own weight and a certain pressure of steam caused by a partial vacuum formed by the flow of steam past the valve exerting a suctional action in the space between valve and spindle. If an accident occurs to a steam-pipe the velocity of the steam increases, and the valve B is closed against its seat, C, and is kept there until A is shut. When the valve A is closed as a stop valve, the flow ceases and the pressure on each side of B is equalised, steam passing to the upper part of the valve through the space between valve and spindle; B then returns to its normal position. An adjusting screw regulates the "difference in pressure" at which the valve closes. Levers D and E are connected by spindles to handwheels for testing purposes, and the valves operate independently until nearly closed, when the force of movement overcomes the friction of the gear. A valve facing F is formed on the spindle, which comes in contact with its

Digitized by Google

seating when A is fully open. This protects the stuffing box. Other types of this valve are made, but the main principles are the same. Other valves are manufactured and give good results; the one described has worked well and may be taken as typical.—S. E. D.

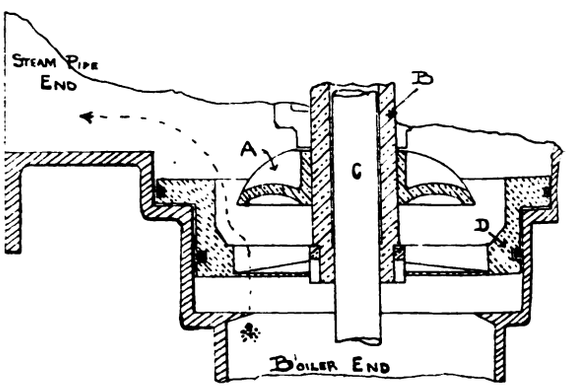
*Answer to No.* 748 (*awarded* 7*s.* 6*d.*).—It is certainly advisable to fit isolating valves to boilers working on one common main, and is now more often done than not; but in no case should isolating valves take the place of a stop valve, but each boiler should be fitted with both, for it is well known by those who have had experience with isolating valves that although they prove very useful in the case of accidents, it is often found that they do not shut off tight enough to enable a man to enter the drum. In addition to being of great service in the case of accidents, they also enable the boilers to be coupled and uncoupled automatically, and so prevent boilers being opened out with pressures higher than that of the main. The sketch shows a valve sold by T. Sugden, Limited, 180, Fleet-street, E.C., which has recently been fitted to two Babcock marine boilers in a station with which the writer is connected. This valve acts as a stop valve, and also closes automatically in both directions. A full description was given in *Engineering* on Jan. 1, 1904. The sketch as here shown is slightly different to that supplied



by the makers, several small details having been left out, but will serve to show its action. The valve is connected to the boiler in the vertical position, as shown, and the steam flows from the boiler in the direction of the arrows. There are two valves, A and B, both being loose on the spindle. The valve A may be screwed down by means of the spindle on to the seat, C. It then acts as an ordinary stop valve. On raising the spindle the valve A is then free to move up or down, according to which side is exposed to the most pressure, it being shut when the pressure of the boiler is less than that of the main. The lower valve, B, will only be lifted to the seat, D, when the pressure of the main is considerably below that of the boiler, caused, for instance, by a burst steam main. Under ordinary working conditions it is kept in the position shown by its own weight, and by a small presssure caused by a partial vacuum formed by the flow of steam. This lower valve can be adjusted to close with any desired difference of pressure by means of an adjusting screw, and after an accident has occurred it can be returned to its normal working position by closing the valve A. The valves A and B can each be separately controlled by wheels on the outside, the object being to keep them in working order, but for the sake of simplicity I have left this gear out in the sketch. The two boilers that we have fitted with this valve are always allowed to couple and shut themselves off automatically, and have always done so in a most perfect manner. So far, however, we have not had a steam main burst, and are therefore unable to give an account of the behaviour under these conditions, but, judging from the principle, there is every reason to believe what is claimed by the makers.—E Austin.

*Answer to No.* 748 (*awarded* 7*s.* 6*d.*).—When two or more boilers are connected up so as to feed into a common main steam-pipe, an isolating valve or non-return valve ought to be fitted in each boiler branch pipe, in addition to the ordinary boiler stop valve. The automatic isolating valve may be either combined with the boiler stop valve in the same casing (which appears to be the latest development of the apparatus), or it may be a separate and distinct valve fitted in the run of the boiler branch steam-pipe. As to whether it is common practice to fit these isolating valves, I am afraid the practice is not so common as it ought to be. There are, no doubt, numerous boiler plants (more especially those of recent construction) provided with isolating valves, but, on the other hand, there are a great many more plants which are not so provided.

The advantages gained by fixing isolating valves are briefly as follows: (1) in case of an accident to the boiler, or to anything on the boiler side of the isolating valve, steam is automatically cut off from the main steam-pipe, and the danger thus localised; (2) it prevents steam being accidentally turned into any empty or laid-off boiler, and is thus a safeguard to anyone working inside the boiler;



(3) in the case of the water getting low in any particular boiler, the safety valve of that boiler has only to discharge the steam generated in the boiler itself, the isolating valve cutting off the steam from the rest of the boilers until such time as it was possible to close the boiler stop valve.

Regarding the second part of the question—viz., "Is there an automatic valve on the market which shuts off the steam supply if a pipe bursts"—there is such a valve made by Messrs. Holden and Brooke, which is a modification of the ordinary type of isolating valve. The working parts are shown in Fig. 1, which shows the valve in the ordinary working position. The valve body, A, is free to slide up and down the sleeve, B; this sleeve in turn is free to slide on the spindle, C (when a stop valve is included with the valve it is fixed on to the lower end of this spindle). The valve seating, D, is fixed on to the sleeve, and is able to move up and down the casing; it is fitted with rings to prevent the passage of steam. A testing lever is fitted on the top end of the sleeve for trying the parts to see that none are sticking. In the case of a steam-pipe bursting, the rush of steam through the valve, and the consequent difference in pressure each side of it, would cause the seating, D, to rise until it jammed against the valve body, A, thus shutting off the steam. To prevent steam backing up into the boiler, in case of burst tubes, low water, etc., the steam pressure will act on the top of the valve body, A, and keep it down on the seat, and thus prevent the steam passing.—J. B. R.

[Other replies to Question No. 748 will be given in our next issue.—Ed. *E. E.*]

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

### QUESTIONS.

757. A steam-driven set, shunt-wound and separately excited, is supplying about 400 arcs, eight in series. They are switched a few circuits at a time in the street. In the event of a breakdown, what is the best way to get on another similar set without sending out men to switch off all circuits?—SPONGY LEAD.

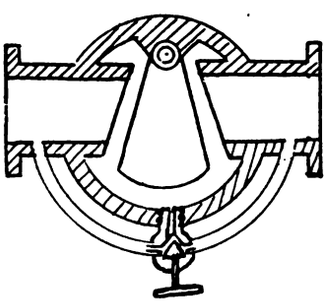
758. Give arguments *pro* and *con.* relating to fuses being fixed on neutral on consumer's main and branch circuits from the station, and fire and personal risk points of view.—M. A. C.

### ANSWERS.

*Question No.* 748.—Where several boilers are working together, is it common practice to fit isolating non-return valves instead of ordinary stop valves? State the advantages of doing so. Is there an automatic valve on the market which shuts off the steam supply when a pipe bursts? If so, describe it.

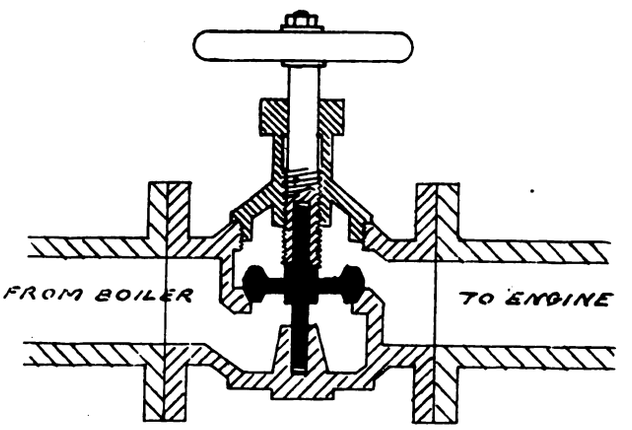
*Answer to No.* 748 (*awarded* 5*s.*).—It is not common practice to rely only upon the isolating valve when several boilers are working on the same range. There are certainly no advantages unless expensive stop valves are objected to on the score of economy. On the other hand, if you rely solely on the isolating valve, should at any time the valve be not properly seated, it would be impossible to clean out the particular boiler to which the valve was attached. Added to this you have no means of stopping priming in a boiler, as with an isolating valve only your valve will always be wide open or shut when using a stop valve. In addition, you have an easy means of slightly wiredrawing your steam, and so reducing your area to a minimum, so that in the event of priming your are safeguarded to a certain extent. The above remarks refer to boilers giving a supply of saturated steam. With superheated steam-boilers, where the superheater forms part of your boiler and is flooded from the boiler drum, it would be very risky, indeed, to dispense with a stop valve unless a thoroughly experienced man was always in charge of your boiler-house plant, as the ordinary stoker is liable to get up pressure, when the result would be disastrous to your engine-room plant and steam range in the event of the superheater not having been drained beforehand. It is usual in this class of boiler to have a notice fixed on the stop valve drawing the attention of the stoker to the necessity of doing so before opening up the boiler on the range. There are several forms of automatic valves on the market which shut off steam in the event of a pipe bursting.

The best example and simplest the writer has seen is a pendulum-pattern valve, as shown in the accompanying



sketch. The small branch pipe is closed when the valve is being used. This is for equalising the pressure on both sides of the valve after repairing the damage. This type of valve, it will be seen, would be more satisfactorily worked when used in conjunction with land or stationary boilers, and would not, I am inclined to think, work well when used aboard ship. Automatic valves are not much used, stop valves having the preference. The writer has never seen one used in practice, but has seen several tried experimentally.—W. F. S.

*Answer to No.* 748 (*awarded* 5*s.*).—The fitting of stop valves having a check valve, or non-return action, although sometimes done, cannot be termed general practice. There are several good forms of non return stop valve on the market. The figure is an illustration of one which not only has a check-valve action, but the valve is reversible.



The diagram will explain itself. There are distinct advantages claimed for a non-return stop valve. In the case of men working in a boiler which is "laid off," an ordinary stop valve may inadvertently be opened, and the men get severely scalded; with a non-return stop valve such an accident would be practically impossible. With boilers working together, one may have the pressure, as shown by its own gauge, supplied by the others; a non-return stop valve will give the engineer a rough idea, at any rate, as to the manner in which the boilers are being fired. Engineers, however, as a rule, prefer stop valves of such a construction that the valve is lifted off its seat by being connected to the spindle. They advance as an objection to the non-return type that the valves have a tendency to stick, and that they are generally unsatisfactory. When a boiler which is one of a number working together is "laid off," the handwheel of the stop valve should be securely fastened; this precaution is taken against its being accidentally opened. The writer is not aware of any automatic valve which shuts off steam supply in the event of a burst pipe. Automatic devices, although many good ones are in constant use, should be carefully examined before being fitted, and if fitted demand constant and skilled supervision that their action may be prompt when required. All such arrangements should be frequently tested, or the engineer may be lulled into a state of false security.—M. M.

*Question No.* 749.—A 200-h.p. three-cylinder gas-engine direct coupled to a dynamo is supplied with producer gas from a holder which is alternately filled and emptied. The engine will run steadily for hours at a time, but sometimes it will suddenly back-fire and pull up. The dynamo is cut out and the speed of the engine brought up again, and the dynamo is then put in again. The engine will then run steadily again. It has been noticed that the engine usually back-fires when the holder is commencing to fill. Give reasons for this.

*Best Answer to No.* 749 (*awarded* 10*s.*).—The name back-firing is sometimes applied to the case where the charge either fails to ignite in the cylinder and afterwards is exploded in the exhaust by the hot products of another explosion from the same or another cylinder, or the exhaust valve not closing properly part of the charge is merely pushed past it instead of being compressed, and the explosion then travels from cylinder to exhaust pipe. The name is also applied to the case where the ignition occurs prematurely, thus acting in the wrong direction on the crank and stopping the engine.

These different phenomena are easily detected in a single-cylinder engine, but they are not so apparent in the case of a three-cylinder engine, thus most likely giving three times

Digitized by Google

as much work to get at the cause of failure. Now, one cylinder only or all three may be at fault, and it may be possible for a careful observer to tell, thus diminishing the labour. The former kind of back-firing is easily known by the violent noise in the exhaust, while the latter may be recognised by a nasty thump on the engine, so that no difficulty will be experienced in classing the behaviour of the engine under one or other of the above heads.

Most likely it will be found that the fault is of the former order, as it is by a long way the commonest. Should this be so, it will be necessary to take out the exhaust valves, or valve, if the faulty one can be located, and see that they are absolutely tight on their seats. A good plan is to make a number of chalk marks across the face of the valve, and drop it on its seat. The whole of the marks should be reproduced on the valve seat, and if they are not, the valve must be ground, or, if necessary, turned and ground until a reproduction of the marks is obtained. Next the spindle should be thoroughly cleaned and lubricated with cylinder oil, as a gritty spindle often causes the valve to stick up against the force of the spring. Care should be taken that the spring is strong enough and properly adjusted to pull the valve sharply to its seat, and that the spindle does not get too hot when the engine is running. If there is a water service to it, carefully see that it is all free and clear. Sometimes the explosions occur in the air-pipe, and, if so, the above treatment should be applied to the air-valve. Another course of exhaust explosions is wrong proportion of mixture; and it would be instructive to know if the engine is governed on a weakened explosion or hit-and-miss system, as if the former, the mixture may sometimes become so strong or so weak that the charge fails to ignite in the cylinder, and subsequently does so in the exhaust. This would be shown by the engine always back-firing at full or light load. Or, again, the cause may be failure of the ignition, due to dirty contact breakers of a magneto-energised spark plug, or defective insulation of the wires, etc., of any spark plug. The plug contacts should, therefore, be well cleaned, and care taken that the wires are well insulated. Or, again, as almost suggested in the question, the holder may be at fault by being too small for its work. But more information would be required before that could be determined. However, if none of the other reasons given meet the case, a new holder of larger capacity must be installed unless there is a defect in the present one. This would, of course, be determined by knowing whether the engine ever did run steadily on full load drawing from that holder.

Premature ignition is a rare occurrence, but if it does occur, it will probably be found that the producer gas is coming over too hot, and the heat generated by compression is sufficient to ignite the charge too early, as there is sure to be either electrical ignition or a timing valve, which cannot get out of time.

If the above points are carefully attended to, there is every likelihood of a satisfactory result, and, in conclusion, it should be again remarked that generally exhaust valves are the causes of failure, and their adjustment must be thoroughly and carefully carried out by a competent engineer.—D. R.

*Answer to No.* 749 (*awarded* 7*s.* 6*d.*).—*Re* your question No. 749 concerning gas-engine three-cylinder types, this class of engine I am fully familiar with. You state that this trouble only occurs when the gasholder is being refilled; there is no doubt but that it is caused by the gas. As you use producer gas, the reason of back-firing is due no doubt to excessive blowing of gas generators causing weakness of your gas, and also to the presence of air and water in same. This, on being admitted through gas-valve to mixing chamber, becomes mixed with the same amount of air that you have been using with good gas, the result being a slowing down of engine in first place due to weak explosion, and back-firing due to engines running slower, therefore, under their work as ignition taking place at same time as when you are running up to speed. It is now the practice on large gas-engines to make the firing slightly later on starting up; also later on larger loads than on light ones, the system used being a three-part commutator for three-cylinder engine. As you state that after your dynamo has been taken out of circuit your engine runs up to speed again, and does the load, this proves that the engine is mechanically perfect, and that there is nothing hot enough to cause pre-ignition, otherwise you would not be able to take up the load again until the engine had cooled down. I should advise you to take particular notice of your gasholder, and to also notice the quality of gas at your inspection burner (this should burn with a light-blue colour, with an orange colour tip at top of flame), and to see that the water is pumped out of gas-pipes every hour. When you notice your engine giving warning (this is easily detected on ammeter), go and reduce your air mixture—say if it is 1 of gas and 1½ air, reduce air to 1—and you will immediately notice engine pick up in speed, and after she has attained full speed gradually put mixture back to proper position. Do this without taking her out of circuit, but if you can ease load, slightly do so. In conclusion, gas-engines are subject at times to back-fires, also pre-ignition and dilatory ignition, which may be caused by many things—viz., improper setting of valves; valves not perfectly tight; dirt under inlet-valve cover face, in this class of engines allowing escape of explosion into mixing chamber, thereby contaminating all the mixtures to other cylinders; oil getting up to the top of the piston and becoming carbonised, and getting lighted by explosion causes mixture to be fired too early; piston and igniters getting too hot. The ignition is the most important factor, and great care and attention should be given to it. As it is found engines run well when gasholder is full, I should endeavour to keep it at one certain height.—S. H. Lee.

*Answer to No.* 749 (*awarded* 5*s.*).—There are two probable reasons of back-firing in a gas-engine: (1) owing to the charge taking fire due to high compression and a consequent high temperature, caused by the cylinder not being kept sufficiently cool; (2) by a piece of incandescent matter in the combustion chamber.

The first cause can be practically eliminated by taking care that there is a good circulation in the water-jacket, and not allowing the charge to be too rich in gas when working at full load. The second cause is also produced by the charge being too rich, and so forming a slight deposit of carbon in the combustion head. This does not necessarily at once cause back-firing, but in time a little of the deposit coats a certain projection in the combustion head, which may only attain a dull red during the compression stroke of the engine, but if a variation in the quality of the incoming charge takes place, it will vary the incandescence of this particle; if richer in air, it will brighten it up; if richer in gas, will deposit more carbon.

The reason of the firing of the three-cylinder gas-engine seems to point to the variation of the quality of the charge. This variation appears to take place during the emptying and charging of the holder, and no doubt just at this moment there is a slight decrease in the pressure of gas, which allows an intake of more air.—J. A.

*Answer to No.* 749 (*awarded* 5*s.*).—It has been the experience of the writer that the successful working of gas-engines depends more on the certainty of action of the igniting gear than on any other detail. Late ignition is one of the main causes of back-firing, as the maximum pressure is not reached until the later part of the stroke. The result is a great loss of power and a very high exhaust pressure, with the consequent strain on the exhaust valve gear, in addition to which there is the liability to overheat the exhaust valve, and to the slow burning of a portion of the gases throughout the exhaust stroke, which, on the opening of the air and gas valves for the admission of another charge, may ignite it, and cause the engine to back-fire.

To obtain the best results from blast-furnace gas of a low calorific value, the ignition tube requires to be kept at an exceedingly high temperature, and the area of the igniting surface should be adequate and well sustained. This can be obtained by using a Bunsen burner with an air-pipe leading from an air supply kept at 3lb. or 4lb. pressure, coupled to the gas-pipe of the burner. The air and gas being thus under pressure, almost any desired heat can be obtained on the ignition tube. It

Digitized by Google

does not always follow that faulty ignition is due to the ignition gear proper. One of the most powerful causes of pre-ignition is the presence of water in the cylinder, due to leakage either through the metal, or to a bad joint in the combustion chamber, thus admitting the water from the jacket. Generally a large proportion of cases of pre-ignition are caused by some deposit in the cylinder, and this, becoming heated by the working of the engine, does not cool down during the exhaust stroke, and thus lights the next charge before the completion of the compression stroke. The deposit is usually traceable to either tar in the gas or to the carbonisation of the lubricating oil, through this latter having too low a flash-point for the temperature of the gas-engine cylinder. The richer the gas the greater is the probability of pre-ignition, this tendency varying directly as the hydrogen content of the gas. It sometimes happens that some foreign matter may get into the air-inlet pipe and be drawn into the cylinder, which, getting hot, will cause pre-ignition. Care should be taken that no portions of valves, etc., coming into the combustion chamber have projections likely to attain an igniting temperature, as, for instance, cotter-pins, stud ends on the end of piston, or any similar projections.

Back-firing is sometimes caused by the valves being wrongly set. The best way to discover this is to take an indicator card and study the diagram, but if this is out of the question, much can be done by turning the engine round by hand and noting the position of the valves. The inlet valve should open just at the beginning and close at the end or immediately after the end of the suction stroke. The exhaust valve should invariably close just as the exhaust stroke is completed. Both valves should be tight at all times, and if they should leak they should be reground to their seats with pumice-stone and oil, but at no time should emery be used.—G. E., JUN.

*Answer to No.* 749 (*awarded* 5*s.*).—The data are insufficient to give more than a few suggestions as to the cause of the back-fires. Whether back-fires are due to one cause or are the resultant of several causes acting together is often a most difficult matter to determine. Experience points to the ignition arrangements as being in nine cases out of ten the cause of the trouble. A dirty piston will sometimes give pre-explosions, thereby wasting a great part of the power as inefficient thrust at dead centre. This state of affairs will soon result in diminished speed. As the engine mentioned in the query generally fails when holder is being first filled, one would attribute the fault to the freshly-made gas not being of good quality. Is the steam pressure correct, and is the steam "dry?" In what condition is the fire in generator when commencing? A poor fire, with plenty of "frogs" in it, may pass on to the holder anything but a suitable gas. Is it possible that between generator and holder leaks may cause the connections to become filled with very dilute gas? Generally, it would appear that for some reason the first gas made is of poor quality. The data given by "R. A. H." do not enable one to point with any degree of confidence as to the cause, or causes, of the "miss-fires."—M. M.

*Answer to No.* 749 (*awarded* 5*s.*).—Back-firing is caused by the charge failing to explode at the proper time, and being discharged to exhaust, is fired by the hot gases of the following charge. Therefore, the problem is to find why the charge was not ignited at the proper time. This can occur when (1) there is not sufficient gas, (2) when air gets into the gasholder. When the gasholder is being filled it is quite possible for the engine to be short of gas for a few strokes, hence the explosive mixture would be too weak to ignite in the cylinder. To find out whether this is the cause or not, hold your hand on the gasbag when you expect back-firing; if the gasbag is not fully inflated after the suction stroke, the engine is short of gas. It is also possible for air to enter the gasholder with the gas or through any leakage when the gasholder is empty. In this case, when the gas is admitted to the holder, it would tend to throw the air to the bottom, near to the engine feed-pipe. Hence the engine would receive an inferior charge when the gasholder was being filled, and back-firing would occur. I think it would be advisable not to allow the gasholder to get emptied.—H. M.

*Question No.* 751.—What is the cause of shrinkage of active material in Faure type negative plates with subsequent loss of capacity? Can capacity be recovered; if so, by what means?

*Answer to No.* 751 (*awarded* 7*s.* 6*d.*).—Although the chemical theories of the accumulator advanced by different authorities are widely at variance, which shows that the accumulator is not properly understood, there is substantial evidence to show that the chemical action produces certain effects which enables the causes to be understood sufficiently well for practical purposes, and it is from this point of view that the following explanation is advanced. It is common knowledge that the temperature of a cell increases during charge and decreases during discharge; consequently this causes both the grid and active material to expand and contract, so that unless the expansion and contraction is equal in both cases, loosening of the paste or apparent shrinkage must follow. The trouble from this source, however, is small compared with the effect on the paste itself. During normal discharge rates sulphate is formed in small quantities, and the action is such as to cause an increase in volume of the active material; and if the cells are allowed to discharge too low, there is danger of breaking the grid or forcing off the active material. During charge the effect is reversed—that is to say, the active material contracts—so that it will be seen that in both cases there is always a tendency to break off particles of the paste or distort the grid if this expansion and contraction be too great The breaking away of the particles makes the actual shrinkage more apparent than real, although shrinkage or contraction really does take place. It will, therefore, be seen that the grid should be so constructed that it can change its volume as that of the active material changes. Inability of designers to meet this requirement causes most troubles in batteries. If, however, the rates of charge and discharge be moderate, the concentration of the acid in the pores of the active material and the chemical actions take place within moderate limits, thereby allowing the active material time to accommodate itself to the changing conditions.

Rapid charge rates are more harmful than rapid discharge rates, owing to the fact that the material in the former case contracts, and, if too rapid, pull loose from the grid. Loss of capacity due to reduction of active material occasioned by the above causes cannot be recovered, but loss of capacity is sometimes brought about by the following causes: (1) clogging of pores of the lead sponges with sulphate or impurities; (2) concentration of the pores; (3) formation of a layer of sulphate between the grid and active material; (4) loss of electrolyte.

In giving a remedy for these troubles I quote from "Storage Battery Engineering," by Lamar Lyndon, B.E., M.E.: "When the plate shows a decreased capacity and exhibits no signs of sulphation, nor loss of material, it will generally be found that the material has shrunken, or the pores are clogged with sulphate and impurities. The rejuvenation of these plates is accomplished by discharging the battery, removing the negative elements, placing them in a bath of 1·200 density sulphuric acid, and connecting them as anodes or in a reverse manner to that in which they are normally connected. As cathodes, "dummy" plates of plain sheet lead about $\frac{1}{16}$in. thick are used. On passing current through the plates, the sponge lead turns first into PbO, then $PbO_2$ as the action continues. When the sponge lead becomes completely peroxidised, the current is again reversed, the acid in the bath first being removed and fresh acid substituted, in order that the impurities may not be redeposited on the negative plates. When the elements are finally converted back into sponge lead and reassembled with the positions, it will be found that the capacity and activity of the battery are increased and brought up to nearly their original condition. Reversal of the complete battery, both positives and negatives, should be avoided if dummies can possibly be secured. If not, however, and the reversing be carefully done, possibly no harm will result to the positive plate. The rate of current flow on reversal, and the change back to sponge lead, should be about one-half of the eight-hour rate, say, as a general rule, ·025 ampere per square inch, or 3½ to 4 amperes per square foot of positive plate (= No. of + plates) × (length) × (width) × 2).

Digitized by Google

The acid in which the change from sponge lead to peroxide takes place should not be used as electrolyte until the impurities discharged by the plates are removed. Loss of electrolyte by evaporation should be made up by proper additions of highly dilute acid—about 5 per cent. acid to 95 per cent. of water. If the liquid does not completely cover the plates, a smaller active mass is exposed, and the capacity proportionally decreased.—A. C.

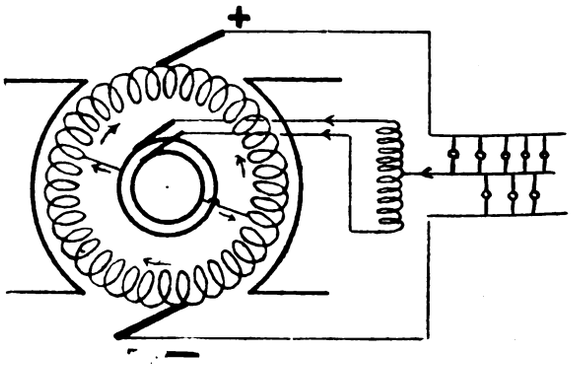
*Answer to No.* 751 (*awarded* 7*s.* 6*d.*).—Doubtless the real object of this question is to ascertain why some of the pellets of "active material" fall from the grids. There is no shrinkage or diminution in bulk in any part of the plates of a secondary leaden battery, but the reverse—viz., an increase in bulk. A short explanation of the chemical effect induced by the electrolytic action of the charging current will make this point clear. For simplicity, we will suppose two plates of lead partly immersed in dilute sulphuric acid, one being attached to the positive pole of the charging circuit, and the other to the negative. The first action of the current is to decompose the water of the liquid so that hydrogen goes in the direction of the current to the plate attached to the negative pole, and therefore called the negative plate of the battery, while oxygen goes to the plate attached to the positive pole. The result of this is to make a film of reduced or pure lead on the "negative" plate, and a film of peroxide of lead on the "positive" plate. While in this state, if we stop the charging current and make the discharging circuit complete, the sulphuric acid in the liquid can attack the reduced lead, but not the peroxide of lead, and therefore we have the conditions of an independent or primary electric battery, and the result of this chemical action, or, as we may call it, the attack of the acid on the reduced lead, is to make it into sulphate of lead. When the next charge occurs, this *used* acid is drawn out of the pores of the lead plate, and, as we know, the density of the electrolyte increases. If we could now examine the surface of the reduced lead under a microscope, we should find it rough and full of pores or dents. Of course, the surface of the lead plate is increased by this action. Now consider the case of a grid of metallic lead with its openings filled by compressed oxide of lead, which is the chemical name of red lead, or litharge. If all is in good order, and the charging and discharging of the "forming" process are properly conducted, a homogeneous plate is the result; but if, on the other hand, any impurity, such as grease or a film of some salt of lead, prevents the "active material" making good electrical contact with the grid, then the charging current would not act upon this partly insulated pellet to the same extent as the rest of the plate. This difference of state would cause local action—*i.e.*, a localised galvanic action—by which the reduced lead would be converted into sulphate, and in time this sulphating action would place a film of sulphate of lead between the pellet and the grid which should hold it. The charging current would draw the sulphuric acid out, and the action would be repeated until a crack might be seen by a microscope between the pellet and the grid, when, of course, the pellet might fall out at any time. These loose pellets must be thrown away, because they are sure to be badly sulphated, but the holes in the plate might be refilled by electrolytically-prepared reduced lead, which would have to be quite fresh, and would have to be pressed tightly into the hole of the plate immediately after charging. This operation would have to be done quickly, as lead freshly reduced gets very hot when in contact with the air, and, of course, heat would spoil the plate. Then the plate, with the new pellet in it, would have to be charged again for a little while before it could safely be discharged, or probably the new pellet would fall out before long. If the battery referred to in the question has sensibly lost capacity, I fear it shows that it has become badly sulphated. This may arise from allowing the battery to stand idle, from over-discharging, or from want of attention to the electrolyte. The best way to get rid of this trouble is to start charging at a fairly low rate and to examine every cell very carefully to see that no pellets or other articles have got lodged in between the plates, and, if so, to remove them at once by means of a lath. The density of each cell should be carefully noted at starting and at the finish. If any cells do not give off gas, look again for short-circuiting pellets, etc., between the plates and underneath them. Extra large bubbles rising during the charge are a sign of this short-circuiting caused by the fallen powder of the plates having mounted from the bottom of the cells to the bottom of the plates. When this happens the cell must be cleaned out. The sediment or dross may be put on one side and sold to the lead smelters who advertise in the *Electrical Engineer*, and the plates and acid solution may be replaced in the clean cell. An easy discharge—*i.e.*, at a rate not exceeding half the usual proper rate of the battery for a short time only—does the battery good, but it should be immediately recharged, and if after that the acid is not found to be up to full strength, a little more must be added, so that the density after a good charge, when plenty of gas is being given off, is 1,200deg. on the hydrometer, neither more nor less. It should be just mentioned here that cleaning out the cells removes or loses a considerable amount of sulphuric acid, partly from spilling and partly because a very large proportion of the dross is sulphate of lead, and, of course, all the dross is soaked with the acid solution. If every step of this process is carefully attended to, the battery will be restored to its original capacity in the course of a few days, but patience and intelligent care are absolutely necessary.—F. G. A.

[Other replies to Question No. 751 will be given in our next issue.—ED. *E. E.*]

## BALANCING CHOKING COIL.

SIR,—May I point out that of the five answers to Question No. 745, which you publish in your issues of Dec. 30 and Jan. 6, there is a certain mistake in no less than three of them, which shows that those who sent these answers did not fully understand the working of the arrangement they were explaining. The correct answers are by "X. Z. Y." and myself. The question reads as follows:

*Question No.* 745.—A direct-current generator of 500 volts, for use on a three-wire system, is fitted with an automatic balancing arrangement, consisting of a choking coil fed, *via* slip-rings, from two points on the armature windings, the middle point of the choking coil being connected to the neutral 'bus bar. Can you give the theory of its action in balancing the pressure of the two sides of the network?



The diagram is from the answer by "X. Z. Y." The current from the middle wire does not flow alternately first through one half and then through the other half of the choking coil, as the incorrect answers state. The inductive action effectually prevents anything of the sort. The out-of-balance current divides equally between the two halves of the choking-coil winding, and is continuous in each.

The total E.M.F. from the central point of the choker to the brush on the heavier loaded side must be the same by either of the two available paths. The only cause for inequality in the two parts of the current is the fact that the paths are always changing in resistance, one increasing while the other is decreasing; but the effect of this, which would alone make the current alternate in the two halves, is almost inappreciable in comparison with the inductive effect of the choking coil, which tends to maintain equality in the two parts of the current in any suitably-designed choker.—Yours, etc., SUPERHEAT.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

### QUESTIONS.

759. It is assumed that mains are about to be laid for supply to a small town on the three-wire continuous-current system, part of the scheme being the entire public lighting by ½-ampere Nernst lamps. What arrangements would you make for switching on all the street lamps from the generating station? The circuits of public lamps must be arranged to approximately balance one another, and precautions must be taken to prevent sudden "kicks" by switching on too many lamps at a time.

### ANSWERS.

*Question No.* 751.—What is the cause of shrinkage of active material in Faure type negative plates with subsequent loss of capacity? Can capacity be recovered; if so, by what means?

*Answer to No.* 751 (*awarded* 5*s.*).—In the two leading makes of batteries it is the practice nowadays to make the negative plates of the Faure type and the positive plates of the Planté type. Provided the positive plates escape buckling, they seem, as a rule, to retain their capacity longer than the negative plates. In a large Tudor battery that was under my care for some time, I noticed the negatives scaling badly at the bottom of the plates. This gradual transformation of the active material of the negative plates into scale, which was in time deposited in the bottom of the cell, was, of course, diminishing the amount of active material, and so reducing the capacity of the negatives. I fancy the cause of this was that the electrolyte at the bottom of the cells was denser than at the top, thus causing the bottom of the plates to be more heavily discharged than the top. When, therefore, the top portion of the plates was nearing the end of discharge, the bottom portion was over-discharged and liable to become sulphated. If a cell is heavily discharged or charged, there is an expansion and contraction of the plate, tending to loosen the plugs of paste. This would in turn affect the capacity, especially if some of the plugs became so loose as to fall out. I was some time ago overhauling a chloride battery that had been in use some years, and was astonished to find that the bottom part of the plates in many cases appeared to be altered in molecular structure. The metal was soft, and pieces of the plate could easily be broken away, and many of the plugs had fallen out. This seems to confirm the theory mentioned above, that the bottom portions of the plates do more work than the top portion.

As for recovering the capacity of the plates, that depends entirely on the condition they are now in. Go through the battery carefully, and notice if any plates have lost many plugs, or are badly buckled; remove these, and burn on new plates. Buckled negative plates are easily straightened between boards, but several makers put antimony into their positive plates, making them stiff and more liable to break if any attempt is made to bend them. If any negative plates are removed from the battery to straighten or scrape the scale off, do not expose them to the action of the air any more than can be helped, as they get hot, and when put back in the battery again they will be found to blister and scale badly. Lift them straight out of the electrolyte, and put them in water. After as much scale as possible has been removed, and any very bad plates renewed, a system of careful charging at a low rate must be started, the charging being kept on a little time after gassing has commenced. Discharge the battery a little below the maker's specified rate of discharge, and carefully note time the cells take to drop to 1·8 volts per cell. Whatever result is got assume in future that this is the capacity of the battery, and do not allow the battery to do more if possible.—W. A. T.

*Answer to No.* 751 (*awarded* 5*s.*).—The actual cause of the shrinkage of active material in Faure negative plates has not hitherto been satisfactorily determined. It is supposed to be due to a gradual filling up of the capillary spaces in the exposed surface of the active material (disintegrated lead) by lead deposited by a galvanic process which commences with the first use of the battery. Continuity of the whole plate is gradually interfered with, causing loss of capacity, both directly and also through the consequent formation of hard sulphate. As time goes on small ruptures may be observed in the plate, the paste becomes much disintegrated, and its union with the plate more insecure. This mechanical failing is increased by the shrinkage and expansion of the active material with each charge and discharge of the cell. Again, the rise in temperature of the acid during operation causes sulphating, accounting for a fairly uniform value for the density of the solution used, about 1·170 at 15deg. C. before charging. Should this value be increased, as is sometimes the case in working traction batteries, the formation of sulphate will be considerably increased, and the capacity reduced.

The deposition of lead referred to is so far without remedy, but it may be possible to improve the condition of the plates and prevent much deterioration by attention to the following details: (1) the electrolyte must be of proper density, and the plates will be protected against sulphating by the addition of ½oz. of sulphate of soda to each gallon of solution; (2) the cells must *never* be discharged below the specified voltage, generally 1·8 per cell; (3) avoid charging at *excessive* rates and *overcharging*.

All excessive working tends to buckling and destruction of the continuity of the plates through the loosening of the paste, with subsequent sulphating, which will also appear if the cells are neglected and run down.—A. M. L.

*Question No.* 752.—Describe what you consider the best method for cleaning the dust off boiler tubes of the Babcock and Wilcox type of boilers, especially where boilers are erected in a cramped position.

*Answer to No* 752 (*awarded* 10*s*).—The usual method of removing the flue dust and soot from the outside of the boiler tubes is by means of a flexible hose with iron end piece (shown in Fig. 1), and it is used very largely with the

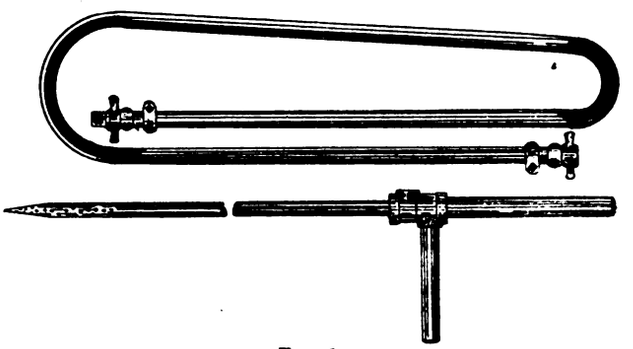

FIG. 1

Babcock and Wilcox boiler. The iron mouthpiece is introduced through side doors built in the brickwork. The standard length of hose for all boilers is 16ft. In cases, however, where the boilers are set in a continuous battery, and consequently the side passage, which is necessary for access to the side cleaning doors, is not available, and also when a method requiring the minimum of labour is desired, then the arrangement of fixed soot-cleaning jets shown in Fig. 2 is used. Upon a suitable attachment on the steam-drum a valve is fixed, to which is attached a three-way cock, an intervening drain-pocket being used to intercept any leakage past the valve. The down-comer pipes, A, to which small nozzles, B, with confined openings are fixed, are built into recesses in the brickwork setting, and the method of operating this form of soot cleaning is confined to opening the valve and turning the cock in the three directions, thus employing the force of the jets of steam through the nozzles for removing soot and dust. The frequency with which this apparatus should be used depends upon the nature of the fuel employed, but it can be used frequently without any difficulty, as the operation only involves opening a valve and turning a three-way cock. Where either of the above-mentioned soot-cleaning arrangements is used, it is advisable to run off any water which may have collected in pipes by blowing through to drain for a few seconds before blowing steam on to the tubes. The writer has found from experience that neglect of this precaution has resulted in the formation of a hard slag on the tops of the tubes, particularly at the

Digitized by Google

front ends of boilers, and which required to be chipped off by hand.

Of the two methods, the writer much prefers the fixed steam-jet arrangement, even in the case of a single boiler. The flexible hose under ordinary working conditions soon becomes worn out, and flexible copper tubing does not make a very good substitute. The material of which the hose is made (largely rubber) soon disintegrates on the inside, and causes the perforations in the cleaning pipe to become choked up, and owing to the bending and twisting which the hose is subjected to when being used the hose and unions soon become leaky, and at the point of its connection to the union the hose gets rotted, and requires shortening and trimming very often.

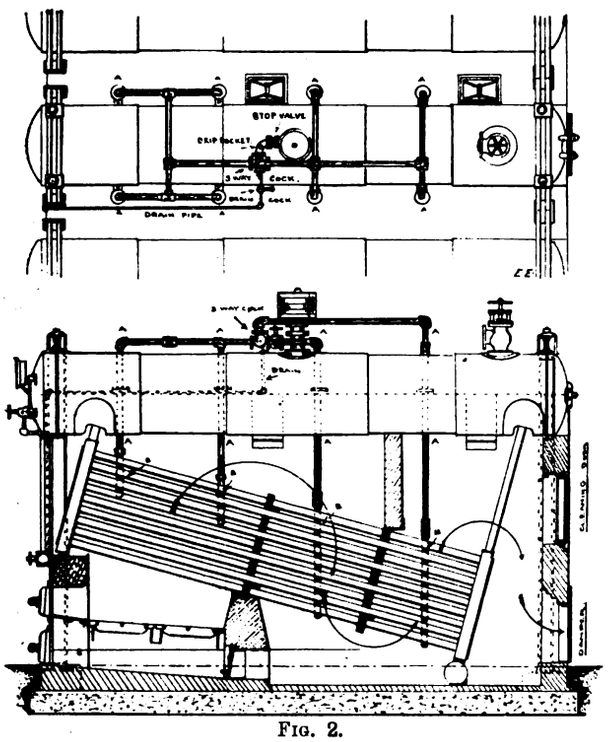

FIG. 2.

The writer has spent many a weary hour in the silent night watches in repairing a burst cleaning hose, the peaceful quiet of the boiler-room only being broken by the stoker with an occasional malediction on all pipes and steam apparatus in general what time he nurses the water blisters on his face and arms. It is not a pleasant experience by any means to be in a narrow passage (side passages between boilers are usually about 3ft. wide), using the hose arrangement, and when after having just inserted the cleaning pipe through one of the doors the hose bursts near to the union on handle of cleaning pipe. The action of the appliances used for cleaning off the soot during working should be assisted, when the boiler is laid off for cleaning, by means of brushes.—S. L.

*Answer to No.* 752 (*awarded* 7*s.* 6*d*).—There are two methods very commonly used for dusting the tubes in a Babcock and Wilcox boiler. (1) Fixed pipes running vertically down inside the brickwork of the boiler with nozzles screwed into them opposite each layer of boiler tubes. Fig. 1 illustrates a 172-h.p. boiler in which this method is adopted. (We have not reproduced this illustration as it is similar to Fig. 2 of the previous answer.—ED., *E. E.*) (2) Frames built into the brickwork at the sides of the boiler with small openings covered by flaps opposite each layer of tubes, through which a steam-pipe can be thrust and moved from side to side. Fig. 2 shows a boiler of the same size which has these frames. Both methods can be used for boilers erected in a cramped position, so it will be best to study the advantages and disadvantages of each.

1. As will be seen from the figure, steam is taken from the bottom of the safety valve, and after passing through a valve is conveyed into the four 2in. pipes on each side of the boiler. Nozzles are fixed in these pipes at proper intervals so that jets of steam are sent over the boiler tubes. The advantage of this method is that the stoker has only to go on top of the boiler and open the valve whenever the tubes want dusting. The disadvantages are (*a*) that the pipes carrying the nozzles have to be very accurately set, as if fixed too low the steam jets will soon blow holes in the sides of the tubes; (*b*) that as the vertical steam-pipes are fixed the steam jets only blow the dust off a portion of the nearest tubes, and widens its range of

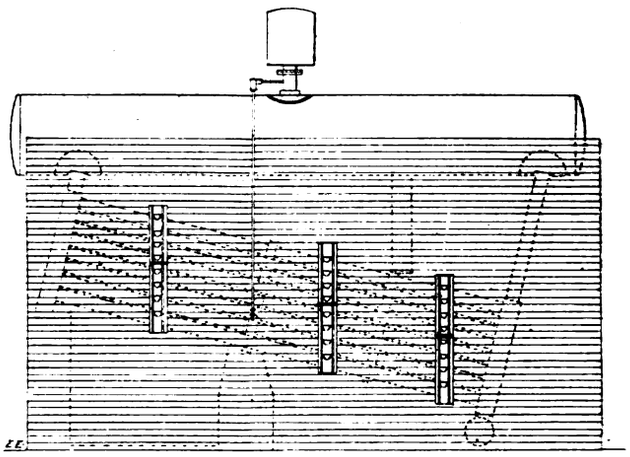

FIG. 2.

action the farther it gets away from the nozzle (this is illustrated in Fig. 3); (*c*) that the nozzles get burnt off with the heat from the flue gases.

2. This is generally considered the better method, and is used in the later boilers. Steam is taken from the top of

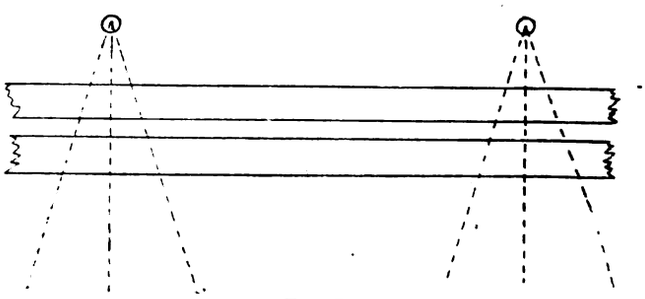

FIG. 3.

the boiler, as in (1), and runs through a ¾in. pipe down the outside of the brickwork. A valve is fixed on the bottom of this pipe, and on to this a rubber pipe is connected of sufficient length to reach to the farthest opening. Cast-iron frames are built into the side of the boilers, having holes in them so spaced that each comes opposite a layer of boiler tubes. One of these frames is shown in Fig. 4. The

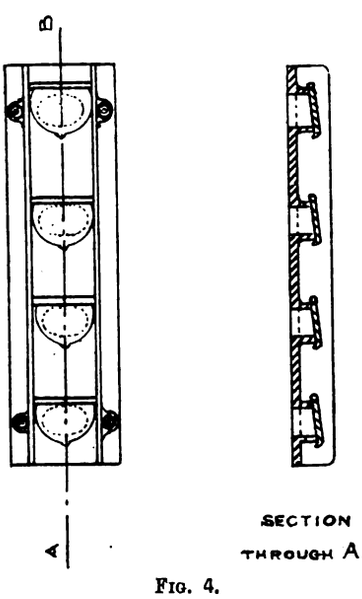

FIG. 4.

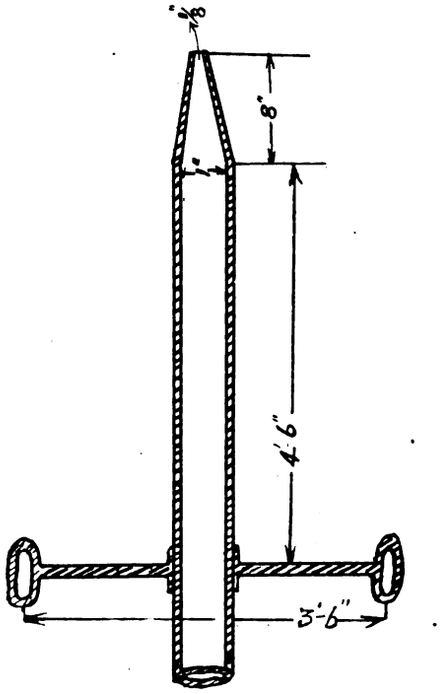
attendant puts the nozzle at the end of the rubber pipe through each of these openings in turn, and sweeps it from side to side, the steam jet thus cleaning the whole length of the tubes. The advantage of this way is that, as the nozzle is fixed to a flexible pipe, the steam cleans every

Digitized by Google

portion of the boiler tubes. The disadvantage is that the operation takes longer than in (1), and necessitates a boiler cleaner to do the work, as the stoker is not able to leave his fires for so long. When the boilers are erected in pairs, these frames are only able to be put up on one side of each boiler, but this is sufficient for keeping the tubes clean.—C. H. LYDALL.

*Answer to No.* 752 (*awarded* 5*s*).—The best method for cleaning the dust off boiler tubes of the Babcock and Wilcox type is to use a steam jet attached to a sufficient length of flexible steel steam tubing to allow any part of the boiler to be reached by the steam jet when the latter is inserted through the various inspection holes in the boiler casing. A form in use by the writer and used on boilers in very confined situations is shown in the sketch.



A length of steam-pipe is fitted at one end with a nozzle, and at the other with a pair of handles and a union for attaching the flexible steam hose. The dimensions shown will give a steam brush with which every part of the tubes can be reached, the nozzle end of the brush, of course, being inserted in the required inspection hole, and then the steam jet directed as desired by working the handles about as required. If the boiler tubes are well swept in this way just as the boiler is shut down, the whole of the dust will be found ready for removal at the bottom of the boiler. Owing to the careless and crude design of the furnace in the majority of water-tube boilers, the hot gases are cooled before they can complete combustion by coming into contact with the comparatively cold-water tubes. With some kinds of coal this leaves a very sticky, tarry deposit on the tubes, and if on examination it is found that the steam brush has not brought this deposit off the tubes, it should be brought off either with a scraper or by tapping the tubes a few times with a light sounding hammer, when the deposit will be loosened, and another application of the steam brush will clean the tubes thoroughly.—W. T. W.

*Answer to No.* 752 (*awarded* 5*s*.).—There are at least two methods in use of removing the dust from the tubes of Babcock and Wilcox boilers. In one a pipe is led down parallel to the boiler walls, with branches at right angles extending between the rows of tubes. These branches are perforated, and the steam issuing through the perforations carries the dust away. By the other method holes are provided in the boiler walls opposite the spaces between the horizontal rows of tubes. Through these holes a "lance," or tube with closed end, is passed, and the steam issuing through perforations made in the last few inches of its length blows the dust off the tubes. The lance is connected to the steam-pipe by means of a flexible hose, the flow of steam through the hose being regulated by means of a cock fixed within reach on the steam-pipe. The hose being flexible, the lance can be moved to and fro and backward and forward over the tubes. When room permits, a straight lance the width of the boiler is used; but when space will not allow of this, the lance can be cut into two or three parts, and a swivel joint, such as is used on a gas-bracket, fitted at the junction of the parts. The lance is kept straight when in use by means of a pin, the insertion of which prevents angular movement at the joints. I have tried replacing the swivel joint by an ordinary pipe union, and screwing and unscrewing the lengths into these when the lance is inserted and withdrawn. I found, however, that the swivel joint was to be preferred. The lance is effective in its work so far as it can reach. The utility of the method first described depends upon the distribution of the perforations along the horizontal branches. Should one or more of these branches get out of order, it may be a very difficult matter to get at them to effect repairs; and if the end should break off, so as to allow the steam to blow straight through instead of through the perforations, the utility of that particular branch would be considerably reduced. If the valve controlling the steam should not be tight, the leakage through it may cause external corrosion of the boiler tubes. But this first method is more convenient than the second to work, as all that is required is to turn on the steam Owing to the drawbacks mentioned, however, it has been superseded in some instances by the "lance" method.—H. J. W.

*Question No.* 753.—Discuss the rules for determining the most economical current density of a one square inch cable, one mile long, insulated in a satisfactory manner, working at a pressure of 1,000 volts direct current, the duration of the maximum load being on an average five hours per day, cost per unit delivered to conductor 1d., and interest and depreciation on cable taken at 10 per cent. State which rule you think gives the best result.

*Answer to No.* 753 (*awarded* 10*s*.).—This problem is the reverse of that generally set to engineers, it being usually necessary to determine the most economical cross-section of cable for a given load. As it is distinctly stated in the question that the load is a varying one, it follows that the current density will also be a varying one, and the problem set is really to find the mean value of the most economical current density. Now, in any cable there are two factors which have a great bearing on the most economical current density—viz.: (*a*) the cost of the energy wasted in the cable per annum; (*b*) the interest on the capital expenditure on the cable, and also the depreciation. It may be as well to state here that the interest and depreciation are usually grouped as one and taken as some percentage of the capital cost of the cable. This, it will be seen, is done in the question. Let us now consider the waste of energy in the cable. This, of course, is dissipated in heat. If at any instant in a cable of resistance R ohms we have a current, C, passing, it is well known that the waste of energy $= C^2 R$ watts, and the cost of waste of energy will be this quantity multiplied by some constant $a$, which we will determine afterwards—*i.e.*:

Cost of waste of energy per annum $= a C^2 R$ £ . . (1)

It will be seen that in practice, when we desire to calculate this cost of waste of energy with a varying current, it will not be correct to take the mean value of the current and square it and substitute in equation (1), but we must take the quantity $C^2$ as the mean value of the squares of the current.

Now let us consider the interest and depreciation of the cable. If the catalogues of all the cable manufacturers be consulted, it will be found that the cost of any cable is very nearly proportional to the weight of copper in the cable. Now, the weight of copper in a cable of given length is directly proportional to its cross-sectional area, which again is inversely proportional to its resistance, so that the cost of a cable may be expressed as $\frac{b}{R}$ £, where $b$ is a constant. Therefore the total cost of a cable and wasted energy per annum, $y$, is expressed as below:

$$y = a C^2 R + \frac{b}{R} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Now, given this equation (2), it is an easy matter to find for what value of R $y$ is a mimimum. Differentiate the equation with respect to R, and we get

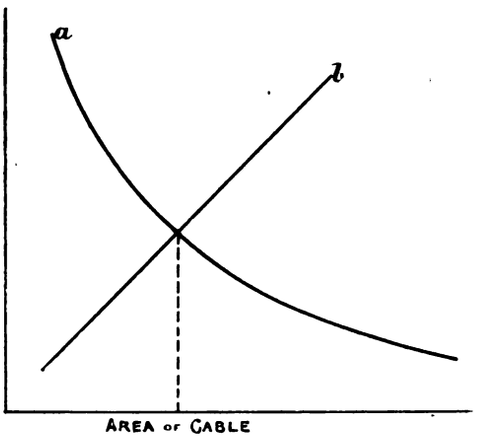
$$\frac{dy}{dR} = a C^2 - \frac{b}{R^2} \quad . \quad . \quad . \quad . \quad . \quad (3)$$

Digitized by Google

Now, $y$ is a minimum when $\frac{dy}{dR} = 0$—*i.e.*, when

$$a\,C^2 = \frac{b}{R^2}, \text{ or when } a\,C^2\,R = \frac{b}{R} \quad . \; . \quad (4)$$

or expressing this result in words we get what is known as Lord Kelvin's rule—*i.e.*, the total cost of a cable and wasted energy per annum is at a minimum when the cost of the waste of energy per annum is equal to the interest and depreciation on the outlay on the cable. This can be better explained by referring to the curves shown. The



point where the two curves cut gives the most economical conditions.

Let us first find the resistance of the cable by the well-known law $R = K\frac{L}{A}$, where L = length of cable in inches; A = area of cross-section of cable in square inches; K = specific resistance of copper. Taking K = ·66 microhm per cubic inch, $R = \frac{\cdot 66}{10^6} \times \frac{63{,}360}{1} = \cdot 0418$ ohm, L being one mile = 63,360in., and A = 1 square inch. ∴ waste of energy = ·0418 $C^2$ watts. One-watt-year = $\frac{24 \times 365}{1{,}000}$ units = 8·76 units. Now, cost of one unit = 1d. = £$\frac{1}{240}$. Cost of one watt-year = 8·76 × £$\frac{1}{240}$ = £·0364. The cost of waste of energy per year = A $C^2$ R = ·0364 × £·0418 $C^2$ = £·00154 $C^2$. The most economical current for the cable is therefore given by the equation below, taking $p$ as the capital cost of the cable in pounds, the interest and depreciation therefore being $\frac{p}{10}$.

$$C^2 \times \cdot 00154 = \frac{p}{10}, \text{ or } C^2 = \frac{p}{\cdot 0154} \quad . \; . \; . \quad (5)$$

Let us now get a close approximation to the capital cost of the cable. The volume of copper in the cable is proportional to its length and area of cross-section—*i.e.*, volume = A × L cubic inches. Now, A = 1 square inch. Take the weight of copper as ·32lb. per cubic inch = $\frac{\cdot 32}{2{,}240}$ tons per cubic inch. Weight of copper in cable = $63{,}360 \times \frac{\cdot 32}{2{,}240}$ tons = 9·05 tons. Take the price of copper as £75 per ton, value of copper in cable = £75 × 9·05 = £679 Let us therefore say that the cost of the cable will be about £1,000. Substituting this in our equation (5) we get

$$C^2 = \frac{p}{\cdot 0154} = \frac{1{,}000}{\cdot 0154} = 65{,}000,$$

or the root mean square (R.M.S.) of current density = 255 amperes per square inch; therefore, the load on the cable must be so proportioned for the most economical condition of working so that the R.M.S. of the current density is 255 amperes per square inch.

During the five hours of maximum load of course the current density will be great, so that it must be diminished during the times of lighter load.—ERNEST P. HOLLIS.

*Answer to No.* 753 (*awarded* 5*s.*).—A cable may be considered as a source of three different expenditures—viz.: (*a*) interest on capital expenditure; (*b*) cost of repairs and renewals; (*c*) energy wasted in the cable in transmission. (*a*) and (*b*) are covered by the 10 per cent. allowed for interest and depreciation per annum. Although the cross-section of a conductor may be determined by the maximum current it has to carry, the total annual loss of energy in the cable does not depend upon the maximum current unless the current is of constant value, which is never the case in practice. Energy will be wasted in the cable *at all loads*, the rate of loss at any instant being proportional to the square of the current. An assumption of the total loss per annum must be made from considerations of the most probable working conditions unless the actual amount be known. Let the loss per day be assumed equivalent to the loss that takes place during the flow of maximum current for $h$ hours. The most economical current density will be that which the cable will carry, under these conditions, with less expenditure than any other cable of different cross-section. That is, the expenditure, including interest on depreciation and cost of energy lost, will be less than that in any cable of greater, or of less, cross-section. Let $X_a$, $X_b$ $X_c$ be the capital cost per mile, including laying, etc., of three cables, the cross-section of the first cable being less than that of the second, and the second less than that of the third, these cross-sections to be of consecutive sizes. Let $r_a$, $r_b$, $r_c$ be their respective resistances per mile, and C the most economical current. Then the total annual cost in each case will be

$$(1) \qquad £\left\{\frac{X_a}{10} + \frac{C^2\,r_a\,h}{24 \times 10^4}\right\} = \left\{\frac{X_a}{10} + K_a\,C^2\right\}.$$

$$(2) \qquad £\left\{\frac{X_b}{10} + \frac{C^2\,r_b\,h}{24 \times 10^4}\right\} = \left\{\frac{X_b}{10} + K_b\,C^2\right\}.$$

$$(3) \qquad £\left\{\frac{X_c}{10} + \frac{C^2\,r_c\,h}{24 \times 10^4}\right\} = \left\{\frac{X_c}{10} + K_c\,C^2\right\}.$$

For (2) to be less than either (1) or (3), the following must hold good:

$$\frac{X_a}{10} + K_a\,C^2 > \frac{X_b}{10} + K_b\,C^2.$$

[A]—*i.e.*, $$C > \sqrt{\frac{X_b - X_a}{10\,(K_a - K_b)}}.$$

Also $$\frac{X_c}{10} + K_c\,C^2 > \frac{X_b}{10} + K_b\,C^2.$$

[B]—*i.e.*, $$C < \sqrt{\frac{X_c - X_b}{10\,(K_b - K_c)}}.$$

For example, let it be required to find the most economical current for cable (*b*), data referring to it and two other cables being as per table following:

| Cable. | Cross-section in sq. in. | Resistance per mile. | 10 per cent. [on cost of cable, £. |
|---|---|---|---|
| (*a*) | ·034 | 1·245 | 10 |
| (*b*) | ·046 | ·915 | 12·5 |
| (*c*) | ·060 | ·761 | 16·8 |

The total loss of energy per day is equivalent to that which would take place if the maximum current flowed for 2½ hours. Then we have

$$K_a = \frac{912{\cdot}5 \times 1\,245}{24 \times 10^4} = \cdot 0047.$$

$$K_b = \frac{912\,5 \times \cdot 915}{24 \times 10^4} = \cdot 0034.$$

$$K_c = \frac{912\,5 \times 761}{24 \times 10^4} = \cdot 0028.$$

By [A] we have $C^2 > \frac{12{\cdot}5 - 10}{\cdot 0047 - 0034}$

*i.e.*, $C > 43\,8$ amperes.

By [B] $C^2 < \frac{16\,8 - 12{\cdot}5}{\cdot 0034 - \cdot 0028}$

*i.e.*, $C < 84\,6$ amperes.

Thus the second cable of resistance 915 ohms per mile will be as economical as the first with a current of 43 8 amperes, and as economical as the third with a current of 84·6, and more economical than either for intermediate values. In practice the current must not be so high as to cause the maximum rise of temperature and pressure drop to exceed the maximum permissible in each case.—H. J. W.

[Other replies to Question No. 753 will be given in our next issue.—ED. *E. E.*]

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

760. What is the method of calculating the repulsion effect of a magnet excited by single-phase alternating current. For instance, it is required to suspend in air a weight of about 4oz. at a distance of ½in. from the end of the magnet. Current available, 35 volts 28 amperes.—REGULUS.

761. In a certain hilly and moorland district, about four or five miles from one of the great towns, there are situated at distances of a quarter to three miles from one another about eight or a dozen ganister quarries and silica brick and firebrick works. At present each has its own separate steam plant for operating the necessary machinery, besides a heavy traction engine and several large wagons, used for taking the manufactures to the nearest railway and for bringing coal up again. What will be the best system to adopt in order to supply all these places from a common power station?—SILICA.

762. A three-wire feeder, ·25, ·125, ·25, which under ordinary circumstances carries 180 amperes, has developed a fault on the + side, and now takes only 80 amperes, the − side taking the same amount as before the fault occurred. The feeder is on the same 'bus bar as other feeders, and feeds into a network box 60 yards from switchboard. The fault is between network box and switchboard. Is there any means of locating same without breaking up the ground? as to do so would be very inconvenient, the feeder crossing a busy thoroughfare. The feeder is laid solid in iron troughing, and is free from earth faults.—W. H. R.

### ANSWERS.

*Question No.* 753.—Discuss the rules for determining the most economical current density of a one square inch cable, one mile long, insulated in a satisfactory manner, working at a pressure of 1,000 volts direct current, the duration of the maximum load being on an average five hours per day, cost per unit delivered to conductor 1d., and interest and depreciation on cable taken at 10 per cent. State which rule you think gives the best result.

*Answer to No.* 753 (*awarded* 10*s.*).—There are three rules by which the economical current density of a cable may be determined—viz: (1) when the total cost of the energy lost in the cable, together with the charges for interest and depreciation, is a minimum; (2) when the ratio of the income from the cable to the total cost of the energy delivered, together with the charges for interest and depreciation, is a maximum; (3) when the net revenue from the cable is a maximum—*i.e.*, when the income from the cable, less the total cost of the energy delivered, together with the charges for interest and depreciation, is a maximum.

These rules may be stated thus: (1) $e+I$ is a maximum; (2) $\frac{E}{G+I}$ is a maximum; (3) $E-(G+I)$ is a maximum, where $e$ = total cost of energy lost in cable or cables per annum; $I$ = charges for interest and depreciation per annum; $E$ = income from cable or cables per annum; $G$ = total cost of energy delivered to cable or cables per annum.

In the example given in the question, $e$ varies as the square of the current density of the cable or cables required to supply a given maximum load. I is 10 per cent. on the cost of cable or cables (laid complete), and varies inversely approximately as the current density for a given maximum load; a one square inch cable may be assumed to cost £3,000 per mile laid complete, and other cables a proportionate figure, for the purposes of these calculations. E varies approximately as the current density of the cable (where only one cable is considered), but for a given maximum load is constant. G varies approximately as the current density of the cable (where only one cable is considered), but for a given maximum load is the sum of a constant and a quantity which varies as $e$. To obtain values of $e$, I, E, and G it is, therefore, necessary to assume different values of current densities, and then by trial to ascertain which value conforms most nearly with the rules given above. Also for these examples we might assume that the price obtained is 3d. per unit, and that the maximum demand on the section under consideration is 1,000 amperes at 1,000 volts. A satisfactory result may be arrived at in a similar way by using any other figures—*e.g.*, the actual figures which obtain in the case for determination. Neglecting the energy delivered to the cable except during the period of maximum load, and assuming that the resistance of one mile (go and return) of table of one square inch section at its working temperature is 0·086 ohm, then the energy lost per annum will be $C^2\left(\frac{0{\cdot}086\times5\times365}{1{,}000}\right)$ units, or 0·157 $C^2$ units, for a one square inch cable, and proportional for extra cables.

The four following examples are given to show approximately how the economical current density may be obtained by using the three rules given above.

*Example* 1.—Assume current density is 1,000 amperes per square inch, then

$e = 0\ 157\ (1{,}000)^2$ units at 1d. per unit $= \frac{157{,}000}{240}$, or £654.

$I$ = £300—*i.e.*, 10 per cent. of £3,000.

$E = 1{,}000\times5\times365$ units at 3d. per unit $= 1{,}825{,}000\times\frac{3}{240}$ or £22,812.

$G = 1{,}825{,}000 + 157{,}000$ units at 1d. per unit $= \frac{1{,}982{,}000}{240}$, or £8,258.

Therefore (1) $e+I = 654+300 = 954$.

(2) $\frac{E}{G+I} = \frac{22{,}812}{8{,}258+300} = 2{\cdot}666$.

(3) $E-(G+I) = 22{,}812-(8{,}258+300) = 14{,}254$.

*Example* 2.—Assume current density is 500 amperes per square inch. Therefore, to supply 1,000 amperes another one square inch cable will be required, and we may, for the purpose of the calculation, assume its cost to be equal to the original one square inch cable. Then

$e = 0{\cdot}157\times(500)^2\times2$ units at 1d. $= \frac{78{,}500}{240}$, or £327.

$I = 300\times2$, or £600.

$E = 500\times2\times5\times365$ units at 3d. $= 1{,}825{,}000\times\frac{3}{240}$, or £22,812.

$G = 1{,}825{,}000 + 78{,}500$ units at 1d. $= \frac{1{,}903{,}500}{240}$, or £7,931.

Therefore (1) $e+I = 327+600 = 927$.

(2) $\frac{E}{G+I} = \frac{22{,}812}{7{,}931+600} = 2{\cdot}674$.

(3) $E-(G+I) = 22{,}812-(7{,}931+600) = 14{,}281$.

*Example* 3.—Assume current density is 750 amperes per square inch. Therefore, to supply 1,000 amperes another one-third square inch cable will be required, and we may, for the purpose of this calculation, assume its cost to be one-third of the cost of the original one square inch cable. Then

$e = 0{\cdot}157\times(750)^2\times1\frac{1}{3}$ units at 1d. $= \frac{117{,}750}{240}$, or £491.

$I = 300\times1\frac{1}{3}$, or £400.

$E = 750\times1\frac{1}{3}\times5\times365$ units at 3d. $= 1{,}825{,}000\times\frac{3}{240}$ or £22,812

$G = 1{,}825{,}000 + 117{,}750$ units at 1d. $= \frac{1{,}942{,}750}{240}$, or £8,095.

Therefore (1) $e+I = 491+400 = 891$.

Digitized by Google

(2) $\frac{E}{G+1} = \frac{22,812}{8,095+400} = 2\,685.$

(3) $E-(G+I) = 22,812-(8,095+400) = 14,317.$

*Example* 4.—Assume current density is 667 ($\frac{2}{3}$ of 1,000) amperes per square inch. Therefore, to supply 1,000 amperes another one-half square inch cable will be required, and we may, for the purpose of this calculation, assume its cost to be one-half of the cost of the original one square inch cable. Then

$e = 0{\cdot}157 \times (\frac{2}{3} \times 1,000)^2 \times 1\frac{1}{2}$ units at 1d. $= \frac{104,667}{240}$, or £436

$I = 300 \times 1\frac{1}{2}$, or £450.

$E = \frac{2}{3} \times 1,000 \times 1\frac{1}{2} \times 5 \times 365$ units at 3d. $= 1,825,000 \times \frac{3}{240}$

or £22,812.

$G = 1,825,000 + 104,667$ units at 1d. $= \frac{1,929\,667}{240}$, or £8,040.

Therefore (1) $e+I = 436+450 = 886.$

(2) $\frac{E}{G+1} = \frac{22\,812}{8,040+450} = 2{\cdot}687.$

(3) $E-(G+I) = 22,812-(8,040+450) = 14,322.$

It will be seen that of the examples taken No. 4 satisfies the conditions, and is approximately correct—viz: (1) is a minimum, (2) is a maximum, (3) is a maximum. Therefore, under the conditions given and assumptions made, a current density of about 700 amperes per square inch would appear to be the most economical.

In most cases of supply cables, as in the present instance, the three rules will give approximately the same result, but in the author's opinion rule (3) is the best to use, as it is very simple and assures the net revenue from the cable being a maximum, which seems to him to be the end desired. The economy of a cable must, of course, be considered in conjunction with prevention of overheating and loss of pressure, and if the rule gives too great a current density the latter must be reduced until overheating is prevented and loss of pressure brought to the desired figure.—H. A. N.

*Question No.* 754.—It is well known that the indicated horse-power of a triple-expansion engine can be varied by altering the cut-off of the intermediate-pressure or low-pressure valve, the high-pressure cut-off meanwhile remaining the same. I am not referring to extreme variations, when the engine almost ceases to be triple-expansion, but to slight alterations in the cut-offs, when the engine is doing equal work in each cylinder. Can anyone explain why this should be so?

*Answer to No.* 754 (*awarded* 10*s.*).—Prof. Weighton, in a paper read before the North-East Coast Institution of Engineers (vol. 16), gives the results of several trials made to determine the most economical point of cut-off in the intermediate (I.P.) and low-pressure (L.P.) cylinders of multiple-expansion engines. It was found that, the cut-off in the H.P. being constant, there was a certain point of cut-off in each of the I.P. and L.P. cylinders at which the engine ran most economically, and this point is given as $\left(\cdot 15+\frac{1}{R}\right)$ stroke, where R is the ratio of the capacity of the cylinder in question to the capacity of the preceding cylinder. It was also found that the cut-off in the I.P. and L.P. cylinders affected the total horse-power developed, the H.P. cut-off being constant, and that in triples the cut-off for maximum power coincides with that for maximum economy in the L.P. cylinder, and is as given above, but that in the I.P. cylinder the maximum power cut-off is much later than the maximum economy.

Considering the I.P. cylinder, it was found that the later the cut-off up to a certain point the greater the horse-power developed by the engine, and that after that certain point the horse-power decreases. Considering the effect of the cut-off, the later the cut-off in the I.P. the lower is the first receiver pressure, and therefore the lower the temperature of the H.P. exhaust. It follows, then, that the temperature range of the H.P. cylinder would increase with the I.P. cut-off, and thus the mean temperature of the H.P. cylinder walls would decrease and the initial condensation increase. But another effect would be that the water initially condensed as above in the H.P. would re-evaporate to do work in the succeeding cylinders; also in the I.P. cylinder a late cut-off would reduce wire-drawing at admission, and reduce the temperature range of the I.P. Thus a larger card would be obtained. After a certain point, however, the receiver drop—H.P. to I.P.—at release in the H.P. would be excessive, and an increase in the I.P. cut-off would decrease the horse-power. Thus it will be seen that there is one point of cut-off in the I.P. cylinder—and on the same basis one point in the L.P. cylinder—which gives a maximum indicated horse-power. A later cut-off means excessive receiver drop, and hence loss in power; an earlier cut-off means excessive condensation in the cylinder or wire-drawing during admission, and a consequent loss in power.—S. E. T.

*Answer to No.* 754 (*awarded* 7*s.* 6*d*).—If the cut-off be kept constant in the H.P. cylinder of a triple-expansion engine and the initial pressure is not altered, the amount of steam admitted per stroke is always the same if we neglect the effect of the cylinder clearance. The total volume of the L.P. cylinder at release is the same whatever the cut-off in that cylinder may be, and, therefore, the number of times the steam has expanded, or the ratio of the volume of H.P. cylinder at cut-off to the volume of L.P. cylinder at release, is constant. Consequently the

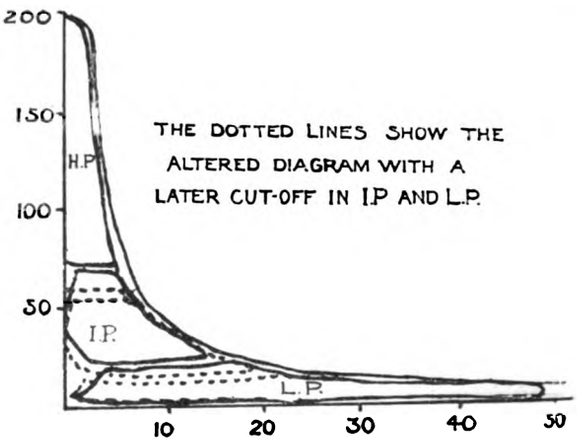

FIG 1.

release pressure of the steam, and the amount of work done by it in the three cylinders, is not affected by the position of the cut-off in the I.P. or L.P. cylinders. The above assumes that the loss by condensation, leakage, etc., is not altered by the alterations in the valve gear. For small variations this assumption is correct. It might be as well to state that if large alterations are made and all the work is thrown on one cylinder, the temperature range will be so large in that cylinder that condensation will be materially assisted. If this cylinder happens to be the H.P, the loss will be made up

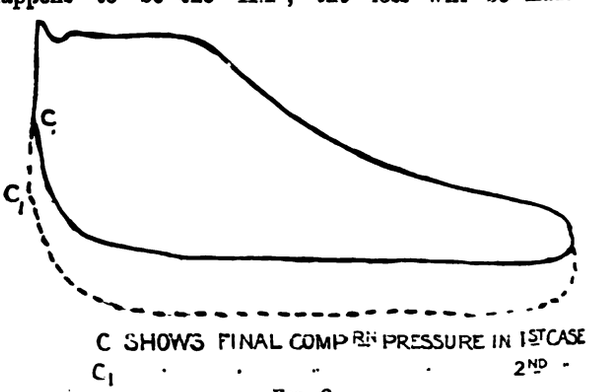

FIG. 2.

by more live steam; this steam will partially re-evaporate later on, and materially increase the total indicated horse-power of the engine. The combined diagram (Fig. 1) shows the redistribution of work between the cylinders if the cut-off is made later in the I.P. and L.P. cylinders. If the H.P. cylinder has a considerable clearance volume, and the back pressure of that cylinder is lowered by making the cut-off in the I.P. later, the compression pressure is reduced (Fig. 2), and thus more steam is required to fill it. This steam gives out work in

Digitized by Google

the next two cylinders, and would thus increase slightly the total indicated horse-power. This effect can also be neglected if the clearance volume is small. The above, of course, only refers to the condition of things when the engine is running steadily. If the cut-off is altered while the engine is running, there will be a considerable momentary alteration of the indicated horse-power as the amount of steam present in the receivers alters, and it must have time to steady itself again.—E. J.

*Answer to No.* 754 (*awarded* 5*s.*).—It is a fact that the indicated horse-power of a triple-expansion engine can be varied by altering the points of cut-off of the I.P. or L.P. valves, though I hardly think it advisable to do this much unless it be to cut off earlier, as it will affect the cushioning at the end of the exhaust stroke of one side of the piston. I think to explain this it will be best to first take any theoretically good imaginary indicator diagram and then see exactly what this shows, afterwards endeavouring to arrive at a conclusion as to what will happen when the cut-offs are altered in either the I.P. or L.P. cylinders.

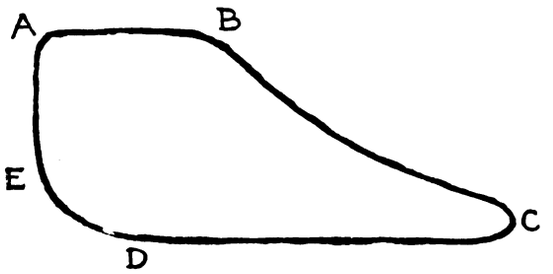

FIG. 1.

Let us take Fig. 1 as being this imaginary diagram. At A the piston has just got to the end of its backward stroke, and is just starting to move forwards again. Steam is behind it, tending to drive it forward, being at a pressure represented by the height of A above the atmospheric line and the inlet valve is still open. This steam pressure behind the piston forces it forwards till the point B is reached in the stroke, when cut-off takes place. At the instant the steam is cut off there is a certain volume and weight of steam behind the piston still at the same pressure as at A, which is practically the same as the boiler pressure, because the steam-inlet valve from the boiler has been open all the time now. From this moment of cut-off onwards to the end of this stroke the steam keeps on expanding, and its pressure correspondingly drops, almost following Boyle's law, which states that the pressure of a gas varies inversely with its volume. At the end of the stroke we have reached the point C, at which the exhaust valve is opened, and the pressure behind the piston immediately drops. The steam is exhausting from this side of the piston into the receiver during all the backward stroke until the point D is reached, at which point the exhaust valve closes. At this point the greater portion of the steam will have passed from the cylinder to the receiver, and only a comparatively small quantity will remain, which is, of course, at the same pressure as that in the receiver. After the exhaust valve has closed, as the piston still comes back, the steam in the cylinder gets compressed, and the pressure therein keeps on increasing till the point E is reached, when the admission valve once more opens. Immediately the pressure in this end of the cylinder rises up to the original pressure again, which is practically the full boiler pressure. We have now followed the action of the steam in the cylinder through one complete cycle or one revolution of our engine, and each succeeding revolution is similar. In the above I have considered more particularly the H.P. cylinder—of course, in either the I.P. or L.P. cylinders the steam cannot come from the boilers straight, but from the receiver, and so its pressure is about the pressure of the receiver.

We are now in a position to consider the action of varying the time of cut-off of the steam in either the I.P. or L.P. cylinders. First, let us suppose that the cut-off in one of these cylinders is made earlier, whilst that in the H.P. cylinder is kept constant. When the intermediate admission valve opens, steam is taken in from the receiver, and hence the pressure in this must drop somewhat, but as the cut-off is earlier, this drop will not be so great as before, and there will be a greater weight of steam also left in the receiver than would otherwise be the case, hence the immediate result as far as the receiver is concerned will be to leave a greater weight of steam at a higher pressure than before. Now, when next the H.P. cylinder exhausts into this receiver, owing to there being already a greater weight of steam at a higher pressure than before, not quite so much steam will exhaust into the receiver, and what is left in the cylinder after the exhaust valve has closed again will be greater by weight, and at a higher pressure than it would otherwise have been. Hence we may state that the immediate result of cutting off earlier in the I.P. cylinder will be to increase the back pressure or cushioning in the H.P. cylinder, and hence lower its indicated horse-power, and also to raise the pressure of the steam in the receiver. As to whether or not this will increase or decrease the indicated horse-power in the I.P. cylinder it is hard to say, as this will depend on how much the pressure in the receiver has risen and by how much the cut-off has been altered. It must also be borne in mind along with this that as the difference in pressures between the steam at admission and exhaust in the H.P. cylinder has been lessened, this will likewise lessen the difference between the temperatures at admission and exhaust; and, hence, as the range of temperature has been slightly lessened, the condensation in the cylinder will also be less, and so the efficiency should be improved.

If, now, the case of making the cut-off in the I.P. cylinder later be considered in a precisely similar manner, it will be found that this proceeding will enable this cylinder to take more steam from the receiver as the admission valve is now open to it longer, and on this valve closing the receiver will be left with a less weight of steam at a lower pressure than under normal conditions. This will have the effect of allowing more steam to exhaust into the receiver from the H.P. cylinder, which will lessen the back pressure and cushioning in this cylinder. Therefore, being less back pressure, the indicated horse-power in this cylinder will be increased. As to the I.P. cylinder itself, this will receive a slightly greater volume and weight of steam than before, but at a lower pressure. What effect this will have on the indicated horse-power of this cylinder it is also hard to say, as this will depend on how much later the cut-off has been made, and by how much the pressure of the steam in the receiver has been lowered, and in any case it will be seen that these two quantities tend to balance one another. Also it will be seen that the range of temperature in the H.P. cylinder will be greater now than normally, which by cooling down the cylinder walls at the end of each stroke will have a tendency to lower the efficiency. In either case, where the cut-off has been made earlier or later, the action of the steam in passing from the I.P. cylinder to the other receiver, and from there to the L.P. cylinder, and from thence either to the atmosphere or the condenser, will be much the same as under ordinary conditions with normal cut-off. Another thing to be borne in mind is the two receiver drops, which will be greater if the cut-off in the I.P. cylinder be later and less if it be earlier, which will tend to neutralise any benefits otherwise obtained by the later cut-off. I think from the foregoing few notes it will be seen that by altering the cut-off in the I.P. cylinder the indicated horse-power in the H.P. cylinder, with regards to pressure, will be altered in the manner pointed out, but as to whether this will actually alter the total indicated horse-power of the engine under consideration it is difficult to predetermine without some definite data, as there are so many things to take into consideration.—E. R. ALEXANDER.

*Answer to No.* 754 (*awarded* 5*s*).—The explanation sought by "J. P." is that by altering the point of cut-off in any engine its power may be either increased or decreased, and that the I.P. and L.P. lines in a triple-expansion engine are in themselves complete engines; consequently if the power be increased or decreased by lengthening or shortening the point of cut-off in either of these lines, the power produced by that line, and consequently the power produced by the triple engine, will be altered. To obtain the highest economy of steam used per horse-power hour, it is necessary to take full advantage of the expansive properties

Digitized by Google

of the steam. This entails an early cut-off and a number of expansions, and if this were carried out in one cylinder excessive cylinder condensation would take place, and the cylinder and engine generally would have to be large and unwieldy for its power, on account of the great strains and the low mean effective pressure, so that no great economy can be looked for from a single-cylinder engine. If, however, two or more cylinders are used, and the cut-off in each cylinder be arranged so that the maximum advantage is obtained by using the steam expansively, but yet not so as to cause great initial condensation or an abnormally low mean effective pressure, and the subsequent cylinder or cylinders to the first be arranged to work with the steam rejected from the preceding cylinder, we obtain an engine giving economy of steam used per horse-power hour and a very even turning effort, provided that each line is adjusted to take an equal share of the load. "J. P." will thus be able to see that by, say, giving a longer cut-off to the intermediate valve of a triple-expansion engine, he will raise the mean effective pressure in the I.P. and L P. cylinders, and consequently will obtain more power from his engine, and *vice versâ*. Whether it is advisable to alter the cut-off in any of the cylinders is a matter which can only be decided by an examination of the engine in question. It has been found by experience that with modern compound and triple expansion engines the best results are obtained by expanding down to a final pressure of 8lb. absolute, with about 6lb. back pressure, the ratio of the cylinders one to another depending on the initial pressure used. The following table shows the cylinder ratios for triple-expansion engines generally adopted:

| Boiler pressure by gauge. | Ratio of cylinder areas. H.P. cylinder. | I.P. cylinder. | L.P. cylinder. |
|---|---|---|---|
| 130 | 1 | 2·25 | 5 |
| 140 | 1 | 2·4 | 5·85 |
| 150 | 1 | 2·55 | 7 |
| 160 | 1 | 2·7 | 7·25 |

—W. T. W.

*Question No.* 755.—An 80ft. brick chimney stack is obliged to be reduced in height by 20ft. To what extent could the loss in draught be remedied by taking the exhaust pipe up the inside of the chimney? At what height should the exhaust pipe enter, and at what distance from the top should it terminate to give the best results?

*Answer to No.* 755 (*awarded* 7*s.* 6*d.*).—As the intensity of the draught produced by a chimney is proportional to its height, reducing the height of the chimney from 80ft. to 60ft. will, other conditions remaining the same, reduce the intensity of the draught by 25 per cent. of its original amount. The draught produced by a chimney may be found approximately by the following formula:

$$D = \frac{7{\cdot}6\ H\ (T - t)}{T \times t},$$

where D = intensity of draught in inches of water pressure;
H = height of chimney in feet above grate surface;
T = absolute temperature of gases inside chimney;
$t$ = absolute temperature of air outside chimney.

Assuming the gases inside chimney to be 600deg. F., and the temperature of the external air 60deg. F., it will be found from the above formula that the intensity of draught produced by a chimney 80ft. high will be approximately equal to ·6in. water pressure, and the draught produced by one of 60ft. high approximately equal to ·45in. water pressure. The loss of draught due to lowering the chimney may therefore be expected to be, say, equal to ·15in. water pressure. This slight loss in intensity of draught can be more than counterbalanced by arranging the exhaust pipe to discharge in the chimney.

The exhaustive or ejective power of an exhaust pipe may be approximately found by using the following formula:

$$E = \frac{37\ d^{1\cdot662} \times p^{0\cdot8}}{D^2},$$

where E = exhaustive power in inches of water pressure;
$d$ = diameter of exhaust pipe in inches;
D = diameter of chimney in inches;
$p$ = pressure of steam at outlet of exhaust pipe.

As the respective diameters of chimney and exhaust pipe are not given in the question it is not possible to give the increased intensity of draught that will be obtained through exhausting in the chimney; but, unless the diameter of the chimney is exceedingly large in comparison with the diameter of the exhaust outlet, the loss of ·15in. in the draught occasioned by shortening the chimney will be more than counterbalanced by the new arrangement, as "A." will find out by making use of the above formulæ.

As regards the point of entry and the height up the chimney at which the exhaust pipe should terminate, providing the chimney is of ample area for the volume of gases it has to discharge, the best arrangement would be for the exhaust pipe to enter the chimney at its base (the bottom of the pipe being provided with a substantial footstep of ample area for supporting the weight of the vertical portion), and be carried up to within a distance from the top of chimney, equal to four or five times the diameter of the chimney; or, assuming the chimney to be 5ft. in diameter, the pipe could be carried up to within 20ft. from the top.—J. B. R.

*Answer to No.* 755 (*awarded* 5*s.*).—The effect of taking the exhaust pipe into the chimney in order to remedy the loss of draught is dependent on the pressure of the steam at the exhaust and the diameter of the chimney and exhaust pipe. This has been shown by Mr. Longridge, who, in the *Proceedings* of the Institution of Civil Engineers, vol. liii., has given the following formula for the exhaustive power of the steam, and which is found to agree very closely with practical results.

Let E = draught in inches of water caused by the exhausting steam;
$d$ = diameter of the exhaust pipe in inches;
D = diameter of the chimney in inches;
$p$ = pressure of the steam in pounds per square inch above the atmosphere.

$$E = \frac{37\ d^{1\cdot662}\ p^{0\cdot8}}{D^2}.$$

The pressure of the steam is dependent on the type and size of the engines. If the engines are triple-expansion it is obvious that the steam will be worked through a larger expansion ratio than if the engines were single-expansion. The diameter of the exhaust pipe will, of course, depend on the quantity of steam to be exhausted, which depends on the size of engine, since in a large engine there is a greater weight of steam passing through the cylinders than in a lesser power engine. The diameter of the chimney is dependent on the quantity of the products of combustion which have to be carried away. It must be remembered that if for any cause the boilers and engines should shut down, that when the fires have to be started again there will be no exhaust, and, therefore, the loss of draught cannot be remedied in any degree until the engines are started. The draught caused by a chimney is found by calculating the weight of the column of gases in the chimney at any moment and subtracting it from the weight of an equal column of air outside the chimney. As the draught of a chimney is usually spoken of in inches of water, the difference of weight found above has to be multiplied by 27·6 to bring it to inches of water, since 1lb. per square inch is equivalent to 27·6in. of water. An approximate rule for finding the draught is to multiply the height of the chimney in feet by ·0075, which gives the draught in inches of water. For the 80ft. chimney this is 80 × ·0075 = ·6in., and for the 60ft. chimney = 60 × ·0075 = ·45in., or the loss of draught is ·15in. of water. Given a good pressure of steam this loss ought to be easily remedied by the exhaust.

The exhaust pipe should be taken in the chimney as soon as possible, in order to minimise the loss of heat by radiation, which will, of course, reduce the pressure of the steam. The exhaust pipe should be placed centrally in the chimney, and should be so situated that the steam, as it spreads out, just misses the top of the entrance of the flue to the chimney, or the steam will attempt to pass down the flue.—Ernest P. Hollis.

[Other replies to Question No. 755 will be given in our next issue.—Ed. *E. E.*]

FEBRUARY 10, 1905.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

### QUESTIONS.

763. What are the advantages of the Alberger or barometric type of condenser over other types commonly in use?—U. C.

764. Give a few simple yet reliable methods of testing cylinder and other lubricating oils, so that a poor consignment may at once be "spotted."—J. A. M.

### ANSWERS.

*Question No.* 755.—An 80ft. brick chimney stack is obliged to be reduced in height by 20ft. To what extent could the loss in draught be remedied by taking the exhaust pipe up the inside of the chimney? At what height should the exhaust pipe enter, and at what distance from the top should it terminate to give the best results?

*Answer to No.* 755 (*awarded* 7*s.* 6*d.*).—I expect the chimney referred to has been found rather unsteady on its foundations, perhaps rocking slightly in a storm, and it has been decided to take 20ft. off the top of the chimney, to do away with the risk of the whole thing collapsing. Naturally the draught of the chimney will be affected. A case very similar to that mentioned by "A." came under my notice some time ago. A chimney 100ft. high and 39in. in internal diameter had an evaporative capacity of 6,600lb. of water per hour. On reducing the height to 80ft., the evaporative capacity was reduced to 5,900lb. per hour. It was decided to take the exhaust pipe into the chimney, and so help the draught. Two or three years after this was done, the owner of the works decided to go in for electric driving, and I was engaged on the work. Amongst other things, it was decided to inspect the bottom of the chimney, to see whether the steam exhausting into the chimney had had any injurious effect. The chimney had been put into first-class condition when it had been shortened, but on examination it was then found that the mortar had disappeared from between the bricks at least one brick deep, thus seriously weakening the foundations. The spaces in between the bricks were filled up with cement, as this was the cheapest and easiest way out of the difficulty. This case shows that it is risky exhausting steam into a brick chimney, and if it can possibly be avoided I should advise "A." to do so. The foundations of the chimney are apparently already unsatisfactory, and the method proposed of increasing the draught would only make them more so. If, however, "A." is determined to risk it, take the exhaust pipe into the chimney about 10ft. from the base, with a short bend turning up into the chimney, but the flange of the bend inside the chimney off, so as to interfere as little as possible with the draught, and also to make it easier to insert the bend. As to what extent the exhausting of the steam into the chimney will affect the draught, that depends on the pressure of the steam in the exhaust pipe, and on wheter the engine is a high or low speed one. Fitting a condenser to the engine would secure better and more economical results than the method suggested.—W. A. T.

*Answer to No.* 755 (*awarded* 5*s.*).—"A." hardly gives enough particulars of his plant to enable a very definite answer to be given, but it will be assumed to be a plant working under average conditions. Turning the exhaust into the stack should certainly not only compensate for the loss incurred by shortening the stack, but should produce a far greater draught than under the original conditions the stack produced. The draught due to an 80ft. stack is ·592in. of water, and that due to a 60ft. stack ·444in. of water, giving a loss of ·148in. of water due to shortening the stack. The idea of turning the exhaust into the stack is that the velocity of the exhaust steam is greater than that of the hot gases within the chimney, and that the steam will impart its velocity to the hot gases, increasing their velocity, and also giving a better draught.

The following formula for finding the velocity of the hot gases in a chimney is based on several experiments which were made on a stack serving Lancashire boilers having well designed and constructed flues:

$$V = \frac{8\sqrt{H}\,(T-t)}{3{\cdot}3\,T},$$

where V = mean velocity of gases in the chimney in feet per second;
T = temperature in degrees F. of the hot gases within the chimney;
$t$ = temperature in degrees F. of the air outside the chimney;
H = height of chimney in feet above the fire-grate.

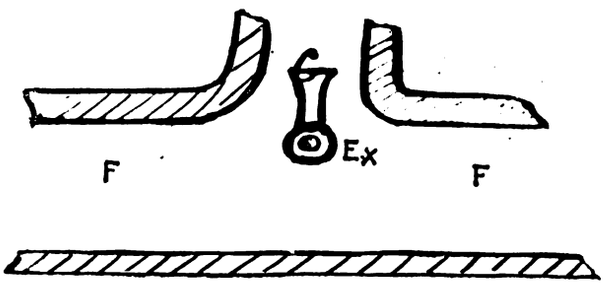
Assuming the following conditions—viz., temperature of gases within the chimney 600deg. F., and temperature of air outside chimney 62deg. F.—on applying the above formula we have:

$$V = \frac{8\sqrt{60}\,(600-62)}{3{\cdot}3\,(600)} = 16{\cdot}8\text{ft. per second.}$$

The velocity of the gases within the chimney being determined as 16·8ft. per second, it is now necessary to assume a value for the velocity of the exhaust gases when turned into the stack. Exhaust pipes are so designed as to permit an easy and free flow for the exhaust steam, the flow being kept, if possible, below 70ft. per second; in many cases 50ft. per second is obtained. To be on the safe side, let us take this lower figure, and then deduct 15ft. per second to allow for the lowering of the velocity of the exhaust steam when admitted to the stack. This gives us 35ft. per second as the velocity of the exhaust steam, and, consequently, the hot gases within the chimney. Again using the above formula, we have

$$35 = \frac{8\sqrt{H}\,(600-62)}{3\,3\,(600)} = 259\text{ft. high.}$$

The effect, then, of turning the exhaust into the stack is to give the draught equal to a chimney stack 259ft. high, and a chimney this height will give a draught equal to 1·91in. of water, so that not only have we been able to make up the loss caused by the shortening of the stack, but have also gained a draught equal to 1·32in. of water.



As to the position of entry of the exhaust pipe into the stack and the distance from the top it should terminate to give the best results, the best method is to bring the exhaust pipe into the bottom of the chimney, and let it run upwards to such a height that the exhaust steam is discharged into the stack about 3in. or 4in. above the level of the tops of the flues, the object being to get the means of producing the draught as near to the flues as possible. There is then less drop in the intensity of draught in the furnaces due to the fact that there is considerably less chance of air being drawn into the flues and chimney at undesirable places. Were the exhaust steam discharged well up the chimney, it can easily be seen that from the above cause alone its effect at the furnaces would be considerably reduced.

The accompanying sketch shows the idea described above. F F are the flues discharging into chimney C, and E X is the exhaust pipe.—W. T. W.

*Question No.* 756.—A 160-h.p., 400-volt, shunt-wound motor, eight-pole type, is started up for the first time on no load, by means of a tramway-type controller having six contacts for the armature resistance. The motor runs well on the first and second contact, but when the controller is moved on to the third contact one of the top set of brushes commences to spark intermittently, and then suddenly there is a vivid electrical discharge between two neighbouring brushes, which are about 9in. apart, and the circuit breakers are thrown out. Various positions of the brushes are tried in close proximity to the sparkless position, but with the same result. Explain the cause and remedy of the above occurrence.

*Answer to No.* 756 (*awarded* 7*s.* 6*d.*).—The cause of the peculiar action mentioned by "J. S. P." may be found either in the motor or else in the controller. If the latter is at fault, there are two possible explanations—namely, either faulty design of resistance on the third step of the controller or else accidental short-circuit of the resistance by faulty workmanship or similar cause in the controller itself. The result of either of the above faults would be to cause a heavy rush of current immediately the controller arm reaches the fourth contact. Tests should be made of the resistance of each step to find out whether the steps are correctly designed. If the controller tests come out correctly, the fault undoubtedly is in the motor itself. In the first place, the shunt winding should be tested to see that the full field strength is on throughout; an ammeter in series with the shunt coils will immediately show a discrepancy in the direction. The armature winding is probably lap-wound, and unless the latter is equalised by means of equalising or "buck" rings, excessive currents will circulate in the armature winding. A complete explanation of the necessity of these "buck" rings was given in the *Electrical Engineer* of June 13, 1902. Of course, if a wave winding is used, these rings are not required. An open circuit or short circuit in any of the coils of the armature would account for the flashing at the commutator and the heavy current, and the writer would recommend "J. S. P." to take a drop test from bar to bar round the commutator. Any fault in the windings will be shown up under these conditions by a low reading on the milli-voltmeter between the bars to which the faulty coil is connected. If the above tests are made, "J. S. P." should have no difficulty in detecting where the present fault in his motor lies.—J.

*Answer to No.* 756 (*awarded* 7*s.* 6*d.*).—The occurrences described would seem to point to one or more of the armature coils being short-circuited. It may be assumed that the controller is properly arranged so as to fully excite the shunt before the armature is switched on. Whilst running at the low speeds corresponding to the first and second contacts, no appreciable effect might be produced by the short-circuited coil or coils, but as soon as the higher speed of the third contact is reached, the heavy current set up in the short-circuited coil might seriously affect the commutation of the neighbouring sections owing to mutual induction, and would cause intermittent sparking to take

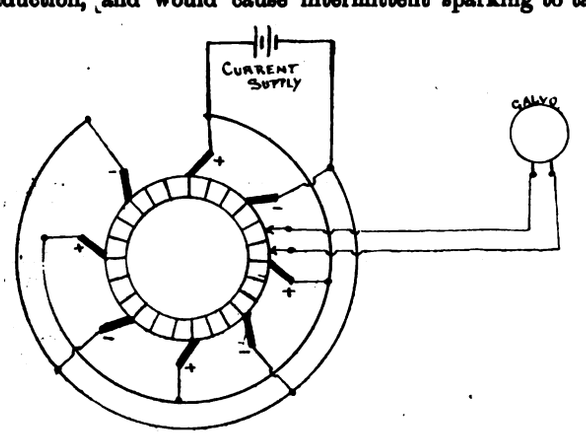

FIG. 1

place once every revolution at each set of brushes in turn (according to the question, such intermittent sparking was only noticed at the top brushes, but it probably also existed, though less obviously, at the other brushes). As the motor speeded up and reached the top speed corresponding to the third contact, the sparking would become sufficiently violent to allow a continuous arc to be drawn out from one brush to the next as the commutator rotated, and so cause a short-circuit of the supply mains and the opening of the circuit breakers. If this is the cause of the trouble, it should be possible by an inspection of the commutator face after the run to decide, by means of the blackening of certain of the commutator plates, as to which section is the short-circuited one. If this is not decisive enough, a simple drop of potential test should be made as follows: Whilst keeping the armature stationary pass a small steady current, say not less than about one quarter the normal full-load current of the machine, through the armature from brush to brush, and by means of any ordinary galvanometer (shunted, if necessary) or milli-voltmeter compare the drop in volts over the different sections of the armature by connecting the galvanometer terminals to neighbouring commutator plates in turn all round the commutator (Fig. 1). When the short-circuited section is reached it will betray itself by a very much reduced throw on the galvanometer, owing to the resistance of that section being reduced by the short-circuit. This coil must then be unsweatted and the necessary repairs carried out.—Q.

*Answer to No.* 756 (*awarded* 5*s.*).—This is by no means an unusual occurrence with new motors, and as a rule it is very easily remedied. In the first place, it would be advisable to thoroughly examine the set of brushes in question, and make sure that they are in good contact with the commutator. Try the tension on each brush and see how it compares with the tension on brushes in another set, and, above all, make quite sure that the spindle carrying the faulty set is perfectly rigid; for it may be that either there is insufficient tension or the spindle is loose, so that when the motor reaches a certain speed the brushes are intermittently thrown off the commutator, and so set up violent sparking, resulting in flashing over. This is a very frequent fault with new motors, and is not unknown with machines that have had considerable running, especially if the brushes do not receive their due amount of attention. The question that now arises is, how is it that the motor runs well on the first and second contact? This may be accounted for in several ways. The current taken by a motor on starting, of course, depends on the applied E.M.F., and this is controlled by the starter. $C = \frac{E - e}{R}$, where C is the current, E the applied E.M.F., and $e$ the back E.M.F. of the motor, and R the resistance in circuit plus the resistance of the armature, from which it is clear that any sudden decrease of R will cause a corresponding increase of C. It therefore might happen that this third contact allows much more current to flow than when on the first and second, so that any fault in brush setting will have a better opportunity of showing itself. This could, of course, be verified by connecting an ammeter in circuit and noting the current taken while changing to different contacts. Another reason for the satisfactory running on the first two contacts may be that the machine is running at lower speed, and loose brushes would be less liable to be thrown off the commutator by vibration. It often happens that machines vibrate much more at certain speeds, and this third contact might give the speed at which vibration is at its maximum. Thirdly, assuming the current to be greater while on this contact, armature reaction will also be greater, and so faulty brushes again have a better opportunity of sparking. Before going further, it will be well to thoroughly investigate these two first causes—namely, faulty brush contact and vibration—for since the sparking starts intermittently, it appears to me that these causes are jointly responsible. We will now give our attention to the field magnets. In new machines it is not altogether uncommon to find that one of the bobbins is partly or entirely short-circuited, which will cause bad sparking at one or more sets of brushes. The best method of testing this is to pass a current round the field magnets and measure the drop in volts across each bobbin. If it is found that the drop across one bobbin is much less than the others, it may be concluded that part of the turns are cut out of circuit, which will weaken the strength of this particular pole, and so set up sparking. This may also often be detected by holding a piece of steel so as to test the field strength, but the former method is most satisfactory. If it is found that any one of the bobbins are

Digitized by Google

devoid of drop, it, of course, follows that it is entirely short-circuited. Bobbins connected so as to give two similar poles next to each other will also cause violent sparking, but will not be confined to one set of brushes. This can easily be detected by holding a compass needle in front of each pole; if it is found that the needle points in the same direction for any two poles side by side, one of the two bobbins must have their ends reversed so as to give opposite polarity. The poles of any motor should be alternately north and south, but, as already stated, if this is not so, it will cause sparking at more than one set of brushes. It is not necessary to give a remedy for each of the above faults, for once located the remedy is obvious.—E. AUSTIN.

*Answer to No.* 756 (*awarded* 5*s.*).—No doubt the phenomenon "J. S. P." records would seem rather remarkable, but I think that I shall be able to explain it, and I give the remedy which I should advise applying. Presumably this motor has never been started up before, as otherwise this faulty connection should have been discovered then and remedied. I think that, perhaps, it will be as well to just briefly describe what happens in running up a shunt-wound motor to speed, so as to make my explanation of this remarkable occurrence clearer. At starting there should be the total strength of current

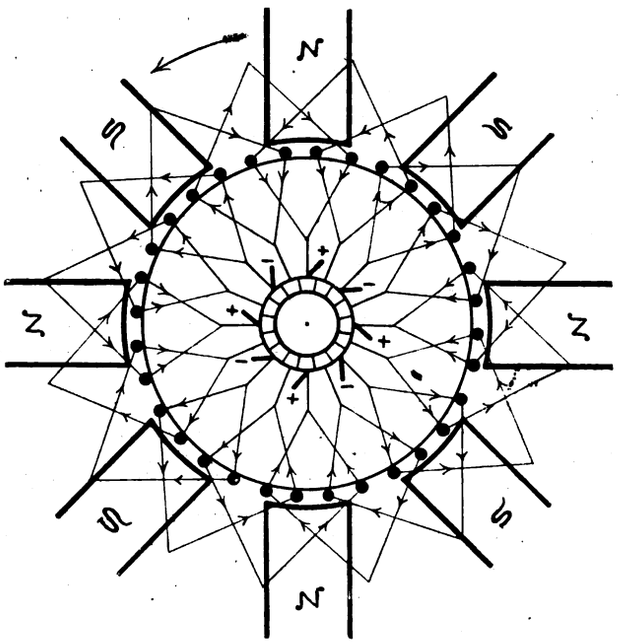

FIG. 1.

through the field coils so as to have the poles fully excited; then, also, the armature currents should pass through a resistance as the motor is at present standing, and this resistance is necessary so as to cut down the magnitude of these currents, as without any external resistance we should simply have in circuit the resistance of the armature, which will be equal to one-eighth of the resistance of the number of armature turns between one positive and an adjacent negative brush, and with only this small resistance in circuit we should, on switching on, have practically a short-circuit across the mains. Having now got the controller on the first contact, the armature will start to revolve with a torque which is proportional to the product of the magnetic flux and the current through the armature. The speed will rapidly accelerate, and the armature current will drop in value. This is because, as soon as the motor starts to revolve, it will generate a back E.M.F., owing to the armature conductors cutting the flux due to the field. This back E.M.F. opposes the impressed E.M.F., and so cuts down the value of the armature current; so that now we have $C_a = \frac{E - e}{R_a}$, where $C_a$ = armature current; E = impressed E.M.F. at terminals of motor; $e$ = back E.M.F. due to armature conductors cutting the field; $R_a$ = resistance of the armature.

When the current has dropped to about the normal value, the controller is switched over to the next notch, which cuts out some of the resistance in the armature circuit, and permits more current to pass through the armature. This increases its torque, which increases the speed, hence increasing the back E.M.F., which causes the current to once more decrease. This cycle of operations is continued till all the armature resistance is cut out and the motor is up to speed. I think the faulty construction or connection in the motor under consideration lies in the fact that one of the field coils is wrongly connected, resulting in either five north and three south poles, or *vice versâ*, instead of it possessing four north and four south poles.

Fig. 1. shows diagrammatically the end view of an eight-pole motor, with the various end connections of the armature conductors, the commutator segments, brushes, etc. The arrow heads indicate the directions of the induced voltages in the windings caused by the armature conductors revolving and cutting the magnetic lines due to the field flux—*i e*, these arrow heads indicate the direction of the back E.M.F. induced in each conductor. It will, of course, be noticed that the direction of the applied E.M.F. is opposite to the induced back E.M.F., which is, of course, as it should be, as the applied E.M.F. will drive current through the armature from the brushes marked + to those marked −, whereas the induced E.M.F. tends to drive current in the opposite direction. In the figure I have assumed that we are looking at the machine from the commutator end, and hence can see the various connections from the segments to the armature conductors. The connections at the back end of the armature I have shown projecting outwards, as otherwise they would not be very clear. All the connections and polarities of the poles are shown on this diagram exactly as they should be, and the arrows indicate the corresponding direction of rotation.

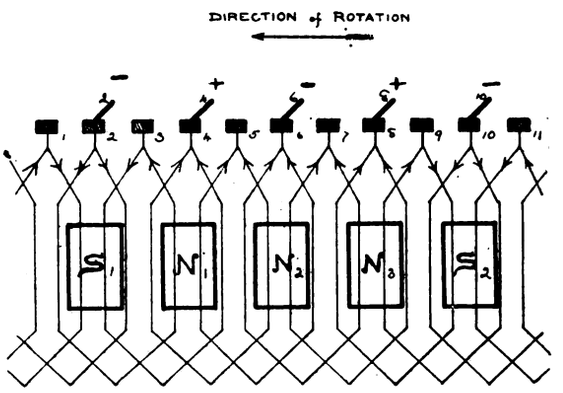

FIG. 2.

Now, in order to demonstrate my point, that if one of the field-magnet bobbins be connected up wrongly, it would give cause to the phenomenon "J. S. P." describes, I will now give another diagram (Fig. 2) showing this winding, etc, developed and laid out flat—*i e.*, as if we were in the centre of Fig. 1, and had a panoramic view of all the connections, poles, etc.—and will this time show it with one of the field coils connected wrongly, so as to make one pole a north instead of a south. The small arrows once again indicate the direction of the induced back E.M.F. in the armature, and the polarity of the brushes connected to the external supply is also shown. The small shaded rectangles at the top represent the commutator segments with the brushes on some of them. The thin lines connecting on to these segments are, of course, the armature conductors and end connections, the bottom of the diagram representing the back end of the armature. It will be noticed that the E.M.F.'s induced in the armature conductors between commutator segments 2 and 4, and also 8 and 10, all oppose the direction of the applied E.M.F.; this is quite as it should be. Now, if the directions of the induced E.M.F.'s in the armature wires between commutator segments 4 and 6 and also 6 and 8 be observed, it will be seen that some of them tend to oppose the applied E.M.F. and some of them tend to assist it. The net resultant of these induced E.M.F.'s will be zero. Hence there will be no back E.M.F. tending to oppose the E.M.F. applied between the brushes,

Digitized by Google

and as the resistance of the armature conductors will be very small, there will be a very big current through these coils from the two + to the − brush between them. The only factor reducing this amount is the resistance in the controller. At first this external resistance, together with the resistance of these armature conductors, is quite sufficient on the first two controller contacts, but on the third, so much external resistance having been now cut out and there being no back E.M.F. to make up for this, there will be a very large current flowing through these brushes, which I will show causes the trouble.

To produce sparkless commutation on a motor, owing to the armature reaction, it is necessary to rock the brushes back a bit so as to have the conductors of the coil which is being commuted in a weak field of the polarity of the pole they are leaving. I have endeavoured to show this in my diagrams. This shifting of the brushes backward tends to demagnetise the poles by an amount which is directly proportional to the current through the coils, and also to the angle through which the brushes have been shifted backward. Consider this action with reference to Fig. 2. Firstly, owing to there being no back E.M.F. between segments 4 and 6 we shall get a large current flowing through the armature from brush 4 to brush 6. This will be greatly above the normal value, and hence its demagnetising effects will be greater than normal. This will weaken pole $N_1$, but $N_2$, which would have been weakened if it were a south pole, being wrongly connected, and hence a north pole, will be strengthened. Similarly, owing to the excessive current from brush 8 to brush 6, pole $N_3$ will be weakened and pole $N_2$ will be strengthened again. The result of this is that $N_1$ and $N_3$, which are of their correct polarity, will be weakened, and $N_2$, which is wrong, will be strengthened. Of course, if the poles are fairly saturated, this will not be so very much in the case of $N_2$. Now, the induced E.M.F.'s in the conductors under $N_2$ must under these conditions be greater than those induced under $N_1$ and $N_3$, and hence the net resultant E M F. induced in these parts of the winding will be in such a direction as to assist the applied E.M.F. instead of opposing it. Now, the current through these armature coils will be given by the formula

$$C_a = \frac{E + e}{R_a},$$

which will be very much above the normal, and this, together with the currents through the other brushes, would be sufficient to open the circuit breakers when the machine flashed over. It will, of course, be observed that this action of demagnetisation of $N_1$ and $N_3$, and the magnetisation of $N_2$, with the consequent result of increasing the induced E.M F. and the armature current, is an action which will keep on increasing. Incidentally, also, it might be mentioned that weakening $N_1$ and $N_3$ will slightly decrease the back E M.F. of the coils under them, and so the currents from brush 4 to brush 2, and also from brush 8 to brush 10, will be slightly greater, but not nearly so much as the other.

Now brush 4 and brush 8 have to carry considerably above the normal full load current, but brush 6 will have to carry more still, as it must carry the extra current passing through each, and hence this will be the brush which started to spark. This, as I said, will get worse and worse, owing to the armature current rising. In a motor of this size there will probably be a difference of potential of eight or ten volts between two adjacent commutator segments. The sparking at the brushes having got so bad, it will form an arc across the segments as they leave the brushes, and this arc will be kept up by the eight or ten volts after it has left the brushes. If this happens with every segment as it passes brush 6 we shall bridge across the commutator sections between brush 6 and brush 4 with a series of arcs, which is the effect mentioned in the question, and which, together with the large current passing through the armature, will bring out the circuit breakers.

I think all the above description should indicate clearly wherein lies the trouble; the remedy is fairly obvious. On consulting Fig. 2 it will be seen that the pole which is wrongly connected up is opposite the brush from which the arc starts, which should be an indication of which is the wrongly connected coil. If "J. S P." excites the field and then goes round trying the polarity of each pole with a small exploring compass, he should easily find out where the wrongly connected one is. If this be then reconnected in the proper manner, the machine should run satisfactorily.

Another possible cause of the trouble if it is not these field connections, might be that the machine and controller are so connected that the shunt current passes through the external starting resistance as well as the armature current. There will be a big drop in volts across this resistance, which will lessen the volts across the field coils and so weaken them. This will lessen the back E.M.F., and hence the armature current will increase, resulting in a bigger drop in the resistance, and so weaken field, etc. This big armature current will exert a considerable demagnetising effect on the field, which will still further weaken the poles and increase the armature current once more. This large current will cause the machine to spark at the brushes, and if one set are not exactly in their correct position—*i.e.*, unequally spaced with respect to the adjacent sets—that might be the set that was worst, and might cause the machine to arc from that set to the next as before. The obvious remedy for this would be to connect up the shunt in the correct manner, so that its current did not pass through the starting resistance. This fault would be shown by the motor racing.

Another cause for the trouble might be that if all the eight field coils were excited in parallel—which, however, I think is very unlikely—there might be a break in one of them. This would cause only half the proper amount of back E.M.F. to be induced in coils under it, and it would be something similar to a short-circuit through the armature and the machine might then arc across the brushes.

Whatever the cause may be, the reason the trouble does not occur till on the third contact of the controller is that until then the external resistance has been sufficient to cut down the current, but that on this contact the external resistance has been lessened to such an extent that the arc may occur.—E. R. ALEXANDER.

[N.B.—We have received another long answer on the same lines as the above from Mr. Alexander, but we think that the effects of a reversed pole would be so great as to prevent the motor from working satisfactorily on the first two contacts of the controller.—ED. *E. E.*]

*Question No.* 757.—A steam-driven set, shunt-wound and separately excited, is supplying about 400 arcs, eight in series. They are switched a few circuits at a time in the street. In the event of a breakdown, what is the best way to get on another similar set without sending out men to switch off all circuits?

*Answer to No.* 757 (*awarded* 7*s.* 6*d.*).—It is the practice in a large central station in which the writer had experience to switch on all the arc circuits, on a somewhat similar though larger installation to the one under discussion, and to run up the dynamo to speed and then switch on the field. In this case, however, there was no shunt field; the machines were separately excited from a 100-volt system. The arc circuits were all controlled from the station, and, as above stated, were switched in before starting up the dynamo. The dynamo was then run up to speed and the field switched on, the voltage then being regulated by the field rheostat. The system works satisfactorily, and no difficulty is experienced in the striking of the arcs or any consequent pumping in the circuits. It would seem that a solution of the question propounded might be found on the above lines, and that if a switch were inserted in the shunt field the above conditions could be reproduced. Suppose it impossible to parallel a new machine with the defective one, or that outside influences compelled a complete shut down, then start up the dynamo with main switches in and shunt field broken. When up to speed, close first the separately excited field and then quickly the shunt field switches, and it would seem that there is little fear that the arcs strike badly or that undue pumping results.—S. E. T.

[Other replies to Question No. 757 will be given in our next issue.—ED. *E. E.*]

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

### QUESTIONS.

765. Explain some simple and effective system of recording on which side of a three-wire supply any new consumer must be connected, giving details as to how any probable out of balance may be quickly looked up for any particular district.—MAINS.

766. A central-station engineer of good experience and ability in running steam-driven stations is appointed to take charge of a plant driven by three-crank vertical high-speed gas-engines, direct coupled, and fed from gas producers. What are the chief points he should watch in order to run with the lowest possible amount of coal per unit generated, together with freedom from breakdowns and a light maintenance bill?—SILICA.

### ANSWERS.

*Question No.* 757.—A steam-driven set, shunt-wound and separately excited, is supplying about 400 arcs, eight in series. They are switched a few circuits at a time in the street. In the event of a breakdown, what is the best way to get on another similar set without sending out men to switch off all circuits?

*Answer to No.* 757 (*awarded* 7*s.* 6*d.*).—It is well known that an arc lamp, at the moment of switching on, takes an excessive current compared to its normal working current, and it is this objectionable feature which must be overcome in the circumstance postulated. It evidently would not do to run the machine up to normal voltage (say 400), and then throw it on the circuit. Any method to be successful must be of the following nature: A sufficient voltage must be put on the circuit to pass the normal working current. The arcs will then commence to "strike," and the current will drop. The voltage may then gradually be raised until the full E.M.F. is on the circuit. Two ways of doing this commend themselves:

1. As the machines are separately excited, the exciting current of the incoming machine must be reduced as low as practicable. The machine should next be switched on to the circuit *and then* started cautiously. As the machine is run up the ammeter will show the condition of the current. If the exciting current and the speed are then *slowly* increased, it will be found that the current will not exceed its normal working value, and that finally the voltage will be normal. The great point is to avoid putting excess pressure (and therefore excess current) upon the circuits until the carbons in the arcs have separated.

2. Another method that might be adopted in cases where the exciting current arrangements did not permit of much regulation, and where slow engine speeds could not be easily obtained, is as follows: Instead of switching the machine directly on to the circuit, it could be switched on through a resistance, and this resistance could be gradually cut out, the final voltage being equal to the normal voltage when eventually all the resistance was cut out. The ammeter in the main circuit would indicate the current, and serve to indicate to the attendant how fast he might cut the resistance out. The best resistance that could be used would probably be a water resistance, which could be quickly made in a wooden tub. Two lead plates of about one square foot area would easily suffice for the normal current (say about 500 amperes). A little acid would be needed in the water.

The machine should be run up to full speed, and one plate being in the liquid, the other should be gradually lowered in, the ammeter being watched closely. The plates should then be brought gradually closer. Finally, when the circuit voltmeter and ammeter showed promising readings the water resistance could be totally cut out by a short-circuiting switch. The water resistance would be best, since it is so easily adjustable and can take such large currents, but it would be an awful nuisance to have to rig up in series with the machine in case of a breakdown, and would only be resorted to in cases where the first method could not be employed. The object of any method that could be successfully employed would be based on considerations of avoiding the current in the main circuit exceeding its normal working value.—T. T.

*Answer to No.* 757 (*awarded* 7*s.* 6*d.*).—The arc lamps being eight in series will, of course, be of such a type that if through any cause one of them should fail to strike an arc, a resistance is inserted in circuit with the remaining seven, such that the drop of potential across the resistance will be equal to the drop of potential across the arc lamp, due to the resistance and back E.M.F. of the arc, if it were struck. If this were not so, it is obvious that the failure of one arc to strike would shut down the remaining seven in series, which would be a serious matter. Now, it is obvious that if the fresh set be run up to speed, and its voltage adjusted to 400 and the main switches put in, all the arcs will attempt to strike at once, the tremendous load being suddenly thrown on the engine will pull it up. Thus it will be seen that we must slowly increase the current in the circuit until all the arcs have struck. This would be a difficult matter if it were not for the resistances being in circuit as described above, as they will be with all the arcs out. This can be best done by using the method here described. First run the engine up to full speed, having the main and field switches out. Then put the regulating rheostat for the field in such a position that all the resistance is in the field circuit, and close the field switch and the main switches. Thus it will be seen that we have the whole system in series with the armature, but as yet there is little or no current flowing, owing to the field of the machine not yet being built up. If we now note the reading on the machine voltmeter, it will probably be zero. Now we must increase the current in the field winding of the generator by cutting out resistance in the field regulating rheostat. This will cause the field to build up, the voltage of the generator will slowly increase, as will the current flowing through the arc-lamp system. It is obvious that we are now applying the load slowly to the engine. Now, it will be seen that owing to the great current passing along the mains there will be a great drop in potential, and therefore there will be a greater difference of potential across the terminals of a set of eight arc lamps nearer the power-house than there will be at the far end of the feeder, so that as we gradually increase the current flowing in the mains, the arcs near the power-house will be the first to strike. It will therefore be seen that as we increase the current flowing through the field winding of the generator, we shall increase the voltage of the machine to such a point that a large enough current will flow through the arc lamps near the power-house, and they will strike, and, finally, the arcs at the far end of the feeder will strike. The voltage of the machine will be finally adjusted to 400 volts. I think this method is the best, because it needs no further resistances to be used other than the ordinary complement of the unit.

The same result could be obtained by inserting a resistance in circuit with the armature of the generator, and then, with the engine running at full speed and the voltage of the generator adjusted to 400 volts, cutting out this resistance slowly, at the same time regulating the field rheostat so as to keep the volts constant. This method, of course, labours under the disadvantage of having the extra resistance for the armature circuit. I have several times had occasion to use the method described, first on an ordinary incandescent lighting circuit, and I find that the time taken to get the fresh set on load is very small indeed.—ERNEST P. HOLLIS.

*Answer to No.* 757 (*awarded* 5*s.*).—From the way in which the question is stated, it appears that the street-lighting is supplied through two special feeders, from which distributors to each street are taken. The best method of getting in a fresh machine after a breakdown has happened is to get the machine turning at about quarter speed and then switch in, controlling the voltage by bringing up the speed and by adjusting the shunt rheostat and bringing up

Digitized by Google

the volts gradually. If this precaution is not taken and the machine run up to speed, fully excited and then switched in, the result will be excessive sparking, and, perhaps, a flash over, a sudden drop in voltage, hunting, and also pumping at the arcs for some time, the reason being that the lamps being out at the time of switching in their carbons are together, and thus present a very easy path for the current; the resistance of this path being much lower than that through the arc, a very excessive current will flow, and will lead to the above results. If, however, the machine is run up and switched in as advised, the time taken from switching in to attaining a normal condition of things will not exceed two minutes, and although the arcs will pump until proper voltage is reached, the moment this is reached they will burn properly.—W. T. W.

*Question No.* 758.—Give arguments *pro* and *con.* relating to fuses being fixed on neutral on consumer's main and branch circuits from the station, and fire and personal risk points of view.

*Answer to No.* 758 (*awarded 7s. 6d.*).—It is evident that if the neutral wire of an installation was made continuous and connected to the earthed main of a three-wire system, there would be no danger of shocks being experienced from contact with the neutral wire or anything touching it. This danger, however, may exist in any badly-erected installation, whether for light or power, and whether neutral is continuous or not, and is due to the wiring being run in metal tubing which is not properly earthed, or to similar causes. This tubing or other object in contact with the wires is quite as likely to become alive from a fault on the supply mains as from a fault on a broken neutral, and the remedy for this danger is not a continuous neutral, but a continuous tubing connected to earth. As far as systems wired with insulated conductors throughout are concerned, the question of fuses or no fuses on the neutral seems to be of little importance. In an earthed concentric system the case is different. If a break is made in the neutral of an installation of this class, the current merely finds its way across the gap through an earth path, and, therefore, fuses are not only useless but dangerous from a fire point of view. Danger from shock in installations of the ordinary type is best prevented by efficiently earthing all parts of the installation which ought not to carry current, such as motor-starter frames, iron-clad switches, etc. Where this precaution is impossible, extra care should be taken in the selection and erection of fittings. Another source of danger is accidental contact with live metal parts, due to failure of the light when the neutral fuse blows. This is really a more serious danger, but may be partially counteracted in the manner suggested lower down, and wholly avoided by the system of covering all live parts with an earthed metal cover. The next point to be considered is the risk of fire from escaping currents, the fire being generally caused by the fusion of a gas-pipe, and the ignition of the escaping gas by a spark or by some exterior means.

The figure represents a house installation on the "distribution board" system, but the reasoning is applicable to any system where the circuits are in parallel. Suppose a fault to earth occurs on circuit 3 in the place shown, part of the return current from circuits 1, 2, and 3 will flow through the fault, and the remainder down the neutral wire, the currents in the two branches being inversely proportional to the resistances of the branches. If the fault is of sufficiently low resistance a considerable current may be shunted, and unless circuit 3 was fused on the neutral side, damage to the wires, and possibly fire, would result. The blowing of the fuse, and in certain cases the dimming of the lights, serves to indicate the faulty circuit; without this happening the only indication of anything unusual would be a deflection of the middle-wire ammeter at the station. The neutral fuse, therefore, should only open the circuit when there is a fault on the neutral wire; the supply fuse ought to deal with all other cases, as when a fuse on the latter side blows the circuit is dead, whereas if the neutral fuse blows the lights go out or become dim, leaving the circuit alive. This may cause accidents, as explained above. To meet this difficulty, the neutral fuses should be heavier than the supply fuses. So much, then, for branch circuits.

The question of fusing the neutral main is very similar. The supply authorities usually instal one set of fuses to protect their meters and wiring, and in series with these are the consumer's fuses, which protect the cables between main fuses and 'bus bars of distribution board. The latter fuses are lighter than the former, so that inconvenience may not be caused by the sealed fuses of the supply authorities blowing, unless there is a fault in their apparatus or wiring. Both neutral fuses should be heavier than supply fuses, for the reason that in the event of a fault occurring on the neutral cable between 'bus bar and street main, the current passing through the fault will be augmented by some of the return current from other installations on the system, just as the current through the fault in Fig. 1 consisted partly of return current from circuits 1 and 2.

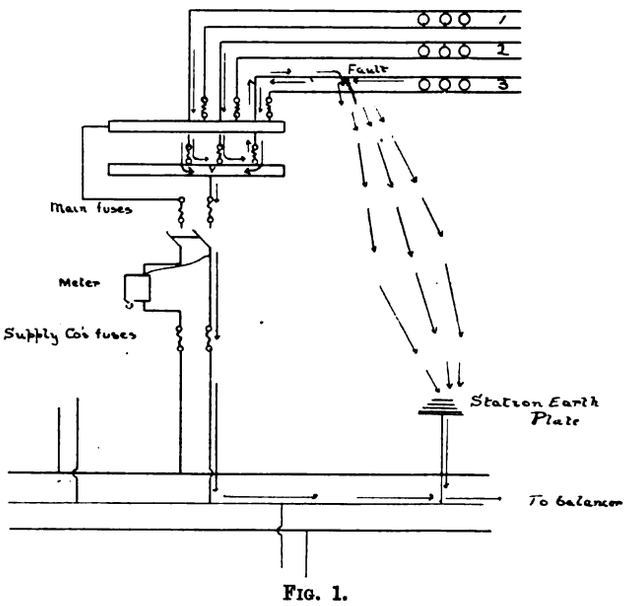

FIG. 1.

The question of expense is too small to be considered. To put the matter briefly: safety from shock is not greatly dependent on a continuous neutral, whereas safety from fire is greatly increased by the use of fuses on the neutral. The utility of a fuse as a fault indicator is also a fact which must not be overlooked. There is but one safe way of abolishing neutral fuses, and this to have a continuously earthed neutral over the whole network. This, however, is a wider subject altogether.—D. HUTCHISON.

*Answer to No.* 758 (*awarded 7s. 6d.*).—It is well known that a double-pole fuse is better protection in all cases than a single-pole, and as most installations connected to the supply mains are practically wired on two-wire system, it is certainly better to have fuses inserted in the leads connected to the neutral conductor of the three-wire system, both from the station and consumers' points of view. If we

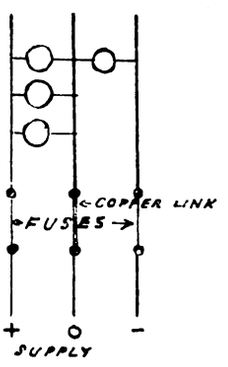

FIG. 1.

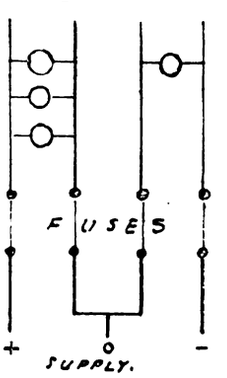

FIG. 2.

consider the following cases, which recently came before the writer's notice, we shall see that the *pros* predominate. For purposes of balancing, the wiring of large buildings is generally arranged so that approximately equal demands are made, at the same time on each side of the three-wire system, to prevent heavy currents flowing in the neutral conductor of the street mains; and in very large installations the three-wire system is maintained within the building (as in Fig. 1), instead of two separate two-wire systems

Digitized by Google

(as shown in Fig. 2). In this case it is essential that the connection to the neutral conductor should be a solid one, as otherwise the blowing of this fuse, say, from overheating due to bad contact, or damage during insertion, would, if the load unbalanced, give excessive pressure on lightly loaded side and low pressure on heavily loaded one, with consequent damage to lamps and apparatus. If the wiring is arranged as in Fig. 2, it will be noticed that the blowing of a fuse, connecting either side to the neutral, will not in any way affect the other side, nor cause dangerous rise of pressure, and will give protection against risks mentioned later. Now, if we consider Fig. 3, and assume that consumer A is connected between negative and neutral and

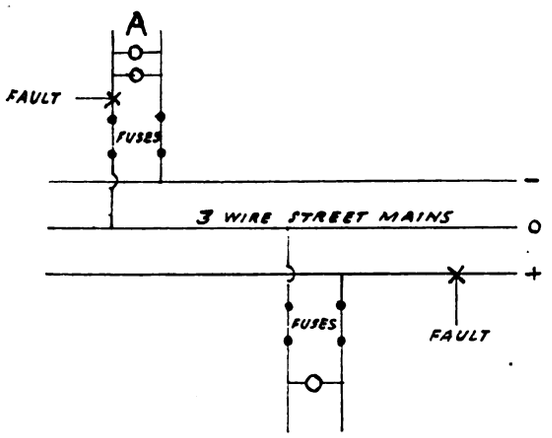

Fig 3.

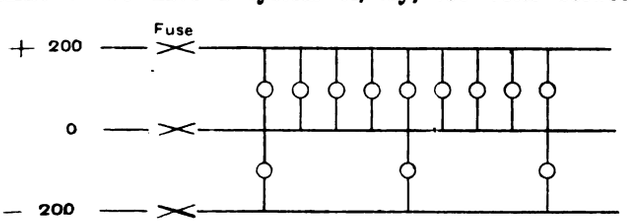
has a metallic contact, say, between one of his main leads and a gas, water, or other earthed body, and that solid connection is made to neutral, it will be seen that a leakage from the positive of street mains or other installation will cause considerable arcing at this contact and probably ignite insulation, with disastrous results; but if we had a fuse inserted, this would be blown and installation isolated. It is also better from the station engineer's point of view to have fuses on neutral, as it is common practice, when slight "earth" exists on this conductor, to put pressure between it and earth and thus blow fuse connecting faulty installation to the mains.—A. T.

*Answer to No.* 758 (*awarded* 5*s*.).—I think that a fuse of any description in a neutral circuit is to be avoided. Let us consider under what conditions a neutral fuse will blow. It must be remembered that the current flowing in a neutral wire is the arithmetical difference between the currents flowing in the outers. Now, for this current in the neutral to be great, it is necessary for the currents in the outers to be greatly out of balance. Of course, if a consumer's main or a branch circuit is only on one side of the system—*i.e.*, the wires used are either positive and neutral or negative and neutral—a fuse in the neutral will perform the same duties as one in the positive (or negative), but even then the outer main is left alive, which is exceedingly undesirable. It must be remembered that if we have a system of, say, 400 volts between



the outers, as shown in the diagram, and through any reason whatever the fuse in the neutral circuit should blow, the neutral circuit only is broken and there is still a passage for the current through the lamps which form the system. Moreover, if the system is considerably out of balance, as will be very likely if the neutral fuse should blow, it will be seen that between the positive and neutral, say, there are a large number of lamps in parallel, and between the neutral and negative a small number of lamps in parallel. These two groups of lamps are therefore in series, and it will be easily seen that as the lesser number of lamps have the greatest combined resistance there will be a greater drop of potential across them than across the larger number, and it is therefore exceedingly probable that these lamps between the neutral and negative will be burnt out. I have had considerable experience with neutral fuses, and I have found that in nearly every case the fuse has blown, the lamps on one side of the system have been burnt out. It follows, of course, that the lamps on the other side of the system will have been extinguished, since the circuit is broken between them and the positive main. Now, if there had been no fuse in the neutral, and any serious trouble had occurred, the fuse in one of the outers would have blown, leaving the neutral and the outer intact, and thus only interfering with the lights on one side. As the cables are only intended to stand 200 volts, a serious breakdown may occur when a neutral fuse blows, since it is shown that it places one cable 400 volts above earth, and if the cable is in a house serious fire risks will be incurred. The element of personal risk is also great, since it is quite conceivable that a switch which will be quite safe with 200 volts will break down under the stress of 400 volts, and serious personal injury may be done to anyone who may touch it. On the other hand, a neutral fuse would be of great use if by any chance a fuse in the outer should arc over instead of blowing completely. This, however, is exceedingly improbable with a properly designed type of modern fuse. I think it is obvious that a fuse in the neutral is a weak point in any system, and that any trouble that may occur should be fully dealt with by the fuses in the outers.—Ernest P. Hollis.

*Answer to No.* 758 (*awarded* 5*s*.).—Taking the question first as to the advisability of placing fuses on the middle wire of a consumer's service mains, such an arrangement would be decidedly disadvantageous to the consumer. In the event of the fuse on middle wire blowing, the two sets of lamps would be in series across the outers, and although the current flowing might not cause the fuses on the outers to go, yet the excess current flowing through that side on which were the fewer lamps might result in dangerously heating the conductors. Such heating might easily cause

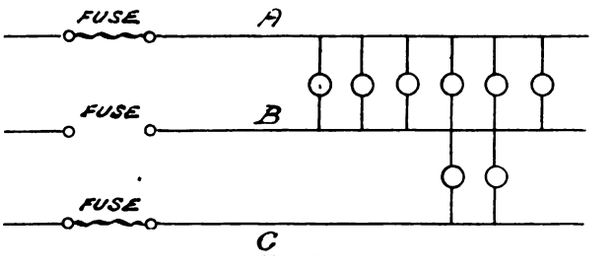


Fig 1.

a fire; besides, there is very considerable danger of spoiling the lamps through their being over-run. Fig. 1 will explain such a condition of affairs. Owing to the unequal loads, there will be a greater drop of potential between B and C than between A and B; the lamps between B and C may therefore be over-run, while those between A and B are insufficiently lighted. There may then be an abnormally large current flowing through the two lamps, such current being enough to burn out lamps or connections, while not enough to blow the fuses on the outers. Suppose, however, that the consumer has his service mains brought to a switchboard (Fig. 2), then local circuits, as D and E, may conveniently be provided with double-pole switches and fuses. The service mains should be fused on outers only, the middle wire being connected by means of a metallic link. This infusible link may be removed, if necessary, for purposes of testing, etc. Should a fault occur in either of the circuits D or E, the blowing of the fuses will only affect that particular circuit on which are the fuses. An advantage with such an arrangement of local circuits is that they may be immediately isolated from the supply mains. It is considered the best practice, when switches or fuses are fitted on the middle wire, to so arrange matters that in the case of fuses the fuse on the neutral wire is the last to go, and in the case of switches that the switch on neutral opens *after* and closes *before* those on the outers. General practice now is to earth the middle wire at the station through a resistance, and to keep the middle wire itself continuous

Digitized by Google

throughout. At feeding points, and where junctions have to be made, instead of fuses infusible metallic links are employed, these links being readily removed if found necessary. A fuse in the neutral is rather a snare than a protection, and except under such conditions as have been specified is unnecessary.—M. M.

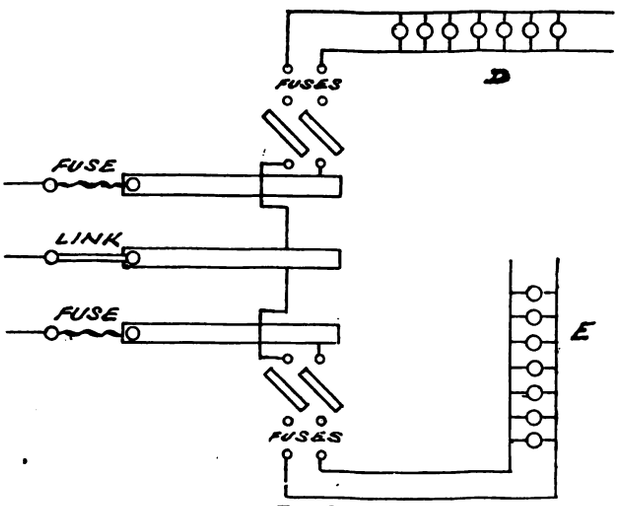

FIG. 2.

*Question No.* 759.—It is assumed that mains are to be laid for supply to a small town on the three-wire continuous-current system, part of the scheme being the entire public lighting by ½-ampere Nernst lamps. What arrangements would you make for switching on all the street lamps from the generating station? The circuits of public lamps must be arranged to approximately balance one another, and precautions must be taken to prevent sudden "kicks" by switching on too many lamps at a time.

*Answer to No.* 759 (*awarded* 7*s.* 6*d.*).—Nernst lamps are getting increasingly popular for street-lighting on account of their low current consumption, good light-giving properties, and of their not wanting much attention. Their chief disadvantage is the uncertainty as to how long they will last. Mr. R. Hammond, in a discussion on Nernst lamps before the Institution of Electrical Engineers in 1903, mentioned that he was trying a mile of street-lighting, using these lamps, and found that the average life of the lamps was 300 hours. They varied from 15 hours to over 1,000 hours. Just recently, in a case I know of, where two miles of street-lighting with Nernst lamps was tried, eight lamps out of 70 gave out the first week. In six cases out of the eight the filament had broken, and in the other two the heating coil had given out. The vibration due to heavy tramway traffic had most likely something to do with the numerous breakages of the filaments. In choosing the type of lamp to use, one should be chosen in which the burner is easily replaceable.

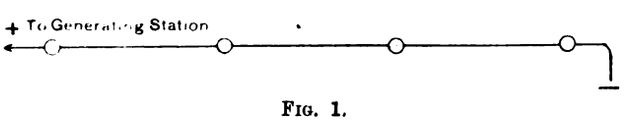

FIG. 1.

As to the method of wiring and balancing the lights there are several alternatives, each with its own advantages. In Fig. 1, 110-volt one-ampere Nernst lamps are wired four in series across the outers at 440 volts. Each set of four lamps is connected to the negative main in the street and to the positive street-lighting main going to the generating station. In this system there is a minimum of jointing and also of cable; also the feeders going to the station only carry half the current that they would do if arranged as in the following two systems. The only disadvantage is that if one lamp goes out, the other three in series do so also. Of course, with this system there is a perfect balance.

Fig. 2 shows the same size lamps, only connected up two in series, and connected to the middle wire. The advantages are that, if one lamp goes out, only one other lamp is affected, and also the attendant at the station can put all the lamps on the positive side of the system, the negative side, or half the lamps on each side. This last is a great convenience in a three-wire station, as it often happens that, however carefully the three-wire system is balanced, sometimes there will be a bigger out-of-balance than the balancers can manage. The attendant could then, by means of a street-lighting switchboard, put all the street

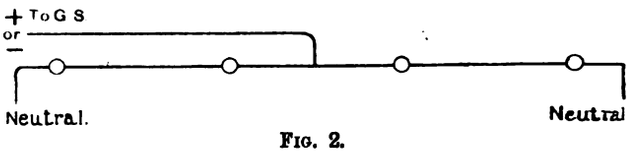

FIG. 2.

Fig. 3 shows 220-volt ½-ampere lamps connected between either of the outers and the neutral main. A broken filament in this case would only affect the lamp itself. The lights on the lightly-loaded side of the system and restore the balance.

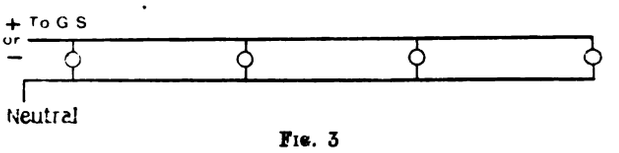

FIG. 3

greatest length of cable would be needed, and the largest number of joints. Under ordinary working conditions the current should always be kept flowing through the lamp in the same direction, otherwise the lamps seem to have a shorter life from some obscure cause.

For ordinary street-lighting have the lamps about 40 yards apart. Well-designed reflectors and globes have a good deal to do with efficient street-lighting. One so often sees the ground at the base of the pole brilliantly

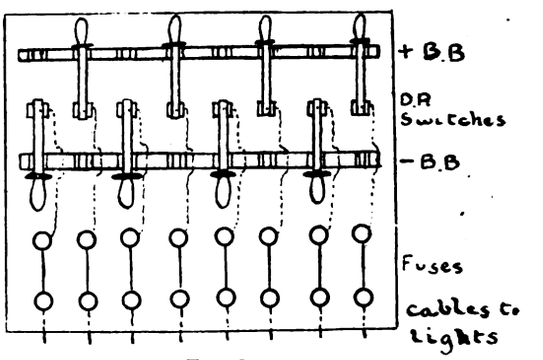

FIG. 4.

illuminated while halfway between the poles dense darkness reigns. Arrange the number of street-lighting cables coming to the switchboard in the generating station so that they average about 20 amperes each. This will avoid any trouble due to out-of-balance, and also if one of these cables break down it will not cause a great number of lights to be put out.—W. A. T.

[Other replies to Question No. 757 will be given in our next issue.—ED. *E. E.*]

## REVIEWS.

**Magnetism and Electricity for the Second-Step Examination of the Board of Education.** By R. WALLACE STEWART, D.Sc.(Lond.). Second edition. Rewritten and enlarged. London: W. B. Clive, University Tutorial Press.

The syllabus of an examination determines the scope and largely the arrangement of any book written primarily for those who desire to pass that examination. This book, however, is far better than the usual examination text-books, and, indeed, forms an exceedingly good book whereby young students can obtain a satisfactory introduction into the subject on which it treats. We have long inclined to the opinion that in teaching the subject we should prefer to reverse the arrangement adopted, and start with "current electricity," leaving "electrostatics" to wind up with. But these views may not be generally held, and even if they are militate nothing against the value of this book, which commences with electrostatics and ends with current electricity.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

767. An isolated three-wire network is fed from a sub-station by means of 100-kw. continuous-current transformers transforming from 2,500 to 440 volts. Two transformers are running at nearly full load, supplying the load and charging a battery at its normal rate—viz., 120 amperes a side—by means of a balancer booster fitted with shunt and series windings on the balancer fields. The motor and generator windings of the transformers are superposed, the high-tension winding being on the outside. These machines are self-exciting, shunt wound, there being also a high-tension series field for starting up, which is cut out automatically when the low-tension field is sufficiently strong. All machines and the battery are fused at about 200 per cent. overload. Under these conditions, if one of the transformer armatures breaks down from high tension to low tension, what will be the effect inside and outside the sub-station, and what approximately will be the extent of the damage?—H. JOSEPH.

### ANSWERS.

*Question No.* 759.—It is assumed that mains are to be laid for supply to a small town on the three-wire continuous-current system, part of the scheme being the entire public lighting by ½-ampere Nernst lamps. What arrangements would you make for switching on all the street lamps from the generating station? The circuits of public lamps must be arranged to approximately balance one another, and precautions must be taken to prevent sudden "kicks" by switching on too many lamps at a time.

*Answer to No.* 759 (*awarded 7s. 6d*).—From the question it is impossible to ascertain whether it is intended to run special mains, through switches and fuses in the generating station, out through the streets, or whether the current for the lamps is to be taken from the ordinary supply mains for the town consumers. This, it will be seen, divides the question into two separate cases, and it will be necessary to attain the end in view in either case by a different method.

Let us first consider the case of where separate cables are laid from the station out under the streets to various feeding points for the lamps. Being a three-wire system, these Nernst lamps will, of course, have been balanced, half having been arranged to be lit from one side and half from the other. The street-lighting mains will enter a sort of feeder pillar which will contain fuses for the lights in each street, and if the three cables—the positive, neutral, and negative—all enter this box the balancing of the load will have been arranged here. Assume that there are several such street-lighting feeders from the station running in different directions, and that they are in no way inter-connected, then, obviously, it would be possible to switch on one feeder at a time at the station, and so minimise the trouble of kicks in the voltage. As a Nernst lamp does not light up instantly, but takes nearly half a minute to warm up before it really lights, this will leave time for the switchboard attendant to adjust his voltage, after first switching on, before the glowers light up. Also, it is improbable that all the lamps switched on will light up at the same instant, but it may take five seconds, say, before they are all on after the first one. If the voltmeters be watched very attentively now, the voltage may be kept pretty steady by means of the shunt rheostat. After a minute or so it will be possible to switch on the next feeder and so on. By this means all the street-lighting may be switched on without having much of a kick on the voltmeter. Another way of doing this occurs to me, and it is this. At the time the street lamps have to go on, the main town supply lighting load will also be coming on. This will, in all probability, necessitate running up another generator, and paralleling it with the one, or ones, at present on load. If the switchboard contains more than one set of 'bus bars, and means are provided for paralleling these sets, it would be possible to run up the new generator, plugging it on to a second set of 'bus bars. Now, if the street-lighting be plugged also on to this separate set, the Nernst lamps can be lit up off this set of 'bus bars. Not so much attention now need be paid to the voltage regulation on these, as, of course, it cannot affect the network. Too high a voltage is very bad for this type of lamp, but too low a voltage will only affect the candle-power for the time being, and will not affect the length of life of the lamps. Now the two sets of 'bus bars can be paralleled, and if it be desired the new generator and the lighting feeders can be plugged on to the main bars. The result is that two operations have been performed in one—*i.e.*, the lamps have been lit up without affecting the voltage on the network, and also a new machine has been paralleled in with the others for the evening load. Exactly similar operations, only in the reverse direction, could be performed when it was time to put out the lamps, care having been taken to work over an amount of the total load equivalent to that taken by the Nernst lamps before separating the two sets of bars. This will prevent any sudden rises in the voltage on the network. It is quite possible that at this time it would not be desired to shut down a generator, in which case the lamps would be switched off a feeder at a time, and the voltage adjusted each time before switching off.

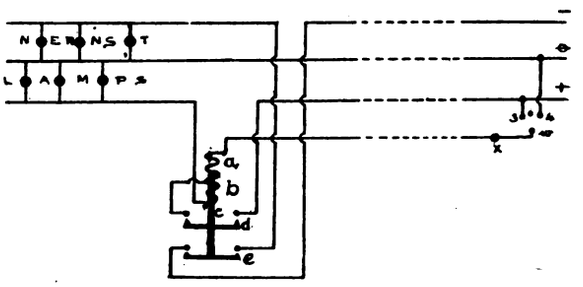

FIG. 1

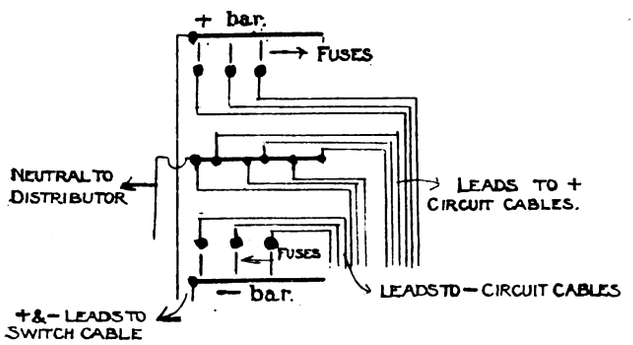
We will now refer to the method to be employed in the case where the Nernst lamps are lit up off the main feeders for the network. These feeders from the station go out straight to feeder pillars in different parts of the town. Here they go through fuses on to a small set of 'bus bars, and from thence through fuses the distributors go in all directions to supply the current to the different consumers. For the street-lighting there would be separate circuits run from this feeder pillar, also through fuses. The question distinctly states that these are to be controlled from the generating station, so some sort of switching apparatus must be also put in this feeder pillar. This will be best to be electrically operated, and I would refer the querist to an article in the *Electrical Engineer* for Aug. 19 and 26, 1904, in which descriptions are given of several kinds of switches for this kind of work. The following description shows the style of arrangement I mean, and it seems to be about as good as any. It is described as a magnetically-locked switch. Fig. 1 is a diagram of the connections, and is similar to Fig. 6 in the *Electrical Engineer*, but this has been added to to allow for three-wire working. The exciting coil, *a b*, consists of two windings—a thin one, actuating the switching in and out, and a thick one (main coil), which serves to hold the switch in the "on" position. In order to light the lamps, the switch, *w*, is put on to contact 3. A current then flows from the positive pole through the switch, lamp *x*, the two windings in series, and the lamps back to the negative or neutral. The core, *c*, is attracted, and the brushes, *d* and *e*, close the circuits. Both ends of *a* are thus connected to the same pole, and *a* carries no

Digitized by Google

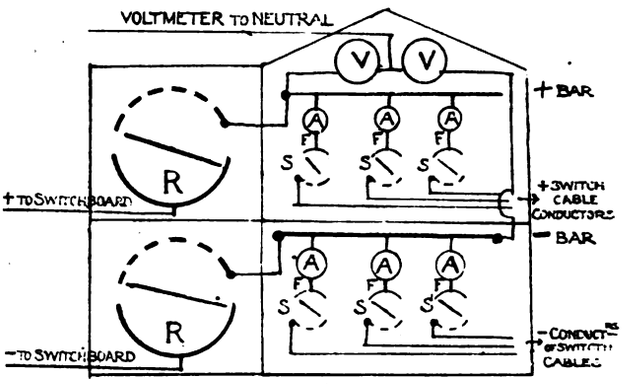
current, whilst the supply flows through *b* in the same direction as on first switching on, and so keeps the switch closed. If the switch, *w*, be moved to contact 4, *a* will receive a current in the opposite direction, and will oppose *b*, so that *c* falls and opens the main contacts. In order to see whether the switch is operating satisfactorily, a lamp has been inserted in the lead connecting the switch, *w*, with the coil *a* in the station. This will only light up whilst switching in or out. If it burns continuously it is a proof that the apparatus is not working correctly. The switches can, of course, be arranged to control as many lamps as is thought advisable, but as far as possible there should be an equal number on each side of the system so as not to upset the existing balance of the network. The smaller the number of lamps controlled per switch the less chance of kicks in the voltage on the network if the lamps be switched on one section at a time, but, of course, the capital cost and the particular features of the situation will determine how many lamps each switch shall control. For the switch wire from the station for controlling the switch a similar wire to the pilot wires for the voltmeter will be very suitable, as there is not much current for it to carry, and that is only momentary at the time of switching on and off. These few notes I think make clear what I should advise doing, and with discretion a reliable system should be the result.—E. R. ALEXANDER.

*Answer to No.* 759 (*awarded* 5*s.*).—In laying down a system of public street-lighting controlled from the generating station, it is necessary to bear in mind that the system must be both simple and reliable, and cheap in first cost, as a heavy capital outlay is a serious barrier to the success of a small lighting station. Assuming that the generating sets are of 50 kw. to 100 kw. capacity, it will be advisable that no more than 10 lamps be switched directly on to the mains, otherwise variations of pressure and "kicks" in the light will be unavoidable. On the other hand, to run switch cables back to the station for every 10 lamps would involve a multiplicity of cables and an unnecessary outlay, and an arrangement, therefore, similar to the following becomes necessary. The town is divided into several sections according to its size and the location of the streets, and in the most central position of each section a switch pillar is placed, from which all the lighting circuits for that section radiate, each circuit being arranged alternately on the positive or negative, so as to balance one against the other as far as possible. The section or switch pillar contains positive, negative, and neutral bars, each circuit cable being coupled, one conductor to the positive or negative 'bus bar through a removable fuse fitting, and the other conductor direct to the neutral bar. By this means each circuit can easily be cut off for testing or repairs, and the renewal of a fuse is a simple matter. The two conductors of the switch cable from the



Arrangement of Switch Pillar.

works are connected direct to the positive and negative bars, and the neutral bar is coupled to the neutral of the nearest distributor. Each section pillar, being balanced in itself, is to all intents and purposes taking a high-voltage supply, thus effecting a saving in copper and main losses, while the out-of-balance current returns direct to the distributor network. The arrangement for supplying the two-wire switch cables from the station is as follows. From the positive and negative 'bus bars of the main switchboard two leads are run to the two bars on the public lighting board through two series resistance, each of which can be adjusted to maintain a constant and steady pressure. (This is a very important point, as on the steadiness of the pressure the success or failure of Nernst lighting depends, and where lamps are directly connected to the distributor steadiness of pressure can seldom be obtained.) The positive and negative conductors of each switch cable are connected to the positive and negative bars through an ammeter, fuse, and resistance switch having two or three contacts, so graduated that the initial current on closing the circuit shall not exceed five or six amperes. By this arrangement the amount of switch cable is reduced to a minimum. There



Arrangement of Lighting Board at Station.

is a high-voltage supply from the station to the section pillar, and the whole of the circuits are easily got at from three or four central positions in the town, whilst the switching on and off and the regulation of the pressure are under the direct control of the switchboard attendant.—B. S.

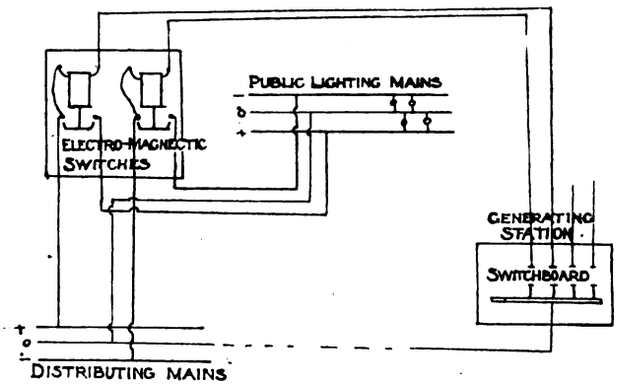
*Answer to No.* 759 (*awarded* 5*s.*).—There are two methods by which public street lamps can be lighted from the generating station—first, by means of special feeders, and, secondly, by means of distance-control switches.

Considering the case of special feeders for the lamps, the conditions of the question require that switching on too many lamps at a time must be avoided to prevent sudden "kicks." For this reason the public lighting network must be divided up into a number of sections, the number of sections depending on the number of lamps. Say it required 240 lamps to light the town, these could be divided into four sections of 60 lamps. Each section would require 15 amperes on each side of the three-wire system. Each section is supplied by a feeder from the station, the feeders being only on the outers, as there is no necessity for middle-wire feeders; the middle-wire cables could all be connected together, and connected on to the public supply network where available. With the second method—viz., distance-controlled switches—the town is divided up into sections, as in the case of feeders being used, but at each feeding point the public lighting network is connected with the distributing mains through an electromagnetic distance-controlled switch. These switches are made in numerous varieties, although they all work on the same principle. A switch is fixed to the core of an electromagnet in such a way that when a current is passing round the coils in one direction the core is sucked in and the switch closed, and held closed until the current is either interrupted or reversed. Some forms of this type of switch have a few coils, in series with the switch, which carry the main current, and serve to hold the switch on, saving the waste of keeping the shunt coils constantly energised. Each section would require two of these switches, one on the positive side and one on the negative side. From the shunt coils of each switch two small wires are connected, one to the distributing main side of the switch, and the other is laid to the generating station, where it is connected to the middle wire 'bus bar through a small switch (as in the sketch). When this switch is closed it will cause a current to pass round the coils of the electromagnetic switch, closing the switch and lighting the lamps. When the small switch is opened the coils

Digitized by Google

release the switch-blade, and the lamps are put out. Some switches depend on the current being reversed in the coils before they will open; in this case it is necessary to run both wires to the station, and connect them through a two-way switch on to the 'bus bars.

As regards balancing, there need be no difficulty in getting the lamps to balance well. Each section should be arranged to be approximately balanced independently. It is not economical to lay a three-wire cable down every street, so it will not be possible to arrange alternate lamps on opposite sides of the three-wire system. Three-wire cables should be laid down the principal streets, and the lamps in one side street arranged to balance with the lamps in the next side street. If the number of lamps in the side streets on one side of the principal street are about equal in number to the lamps in the side streets on the other side, the lamps in the streets on one side of the main street could all be on the positive side, and the lamps in the streets on the other side all on the negative side of the system.



The decision as to which system is to be used will depend on the size and shape of the town, and also on the amount of capital which can be spent. It is generally found cheaper to instal distance-controlled switches than special feeders; in a compact, small town, which is rarely met with, it might be as cheap in the long run to lay feeders. With the distance-controlled switches the distributing mains have to be of a larger size to carry the public lighting supply; the switches themselves are sometimes apt to stick, and necessitate a journey round to set things right. They should be fitted in pillars as free from dampness as possible, and should be kept clean.—J. B. R.

*Question No.* 760.—What is the method of calculating the repulsion effect of a magnet excited by single-phase alternating current. For instance, it is required to suspend in air a weight of about 4oz. at a distance of ½in. from the end of the magnet. Current available, 35 volts 28 amperes.

*Answer to No.* 760 (*awarded* 7*s.* 6*d.*).—If a conductor be situated in an alternating magnetic field, and at any instant the strength of the field be B lines per square centimetre, the force, F, tending to repel the conductor in a direction parallel to the direction of the field is given by the equation

$$F = \frac{B^2 \mu}{8\pi} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

where $\mu$ is the magnetic permeability of the conductor. I shall not prove this equation (1), because, in the first place, the method of proving it is very long and intricate, involving higher calculus; and, in the second place, it is of little interest to practical engineers. However, if any reader requires the proof, it can be found in J. J. Thomson's "Elements of Electricity and Magnetism," Chapter XI. We will, however, suppose that our conductor is not one of the magnetic elements, and, therefore, has a permeability of 1, so that $\mu$ disappears from the expression. Equation (1) gives the repulsion at any instant, but since here B is proportional to cos $(p\,t + \phi)$ the mean value of $B^2$ is $\frac{H^2}{2}$, where H is the maximum value of B. Therefore, the mean value of the repulsion is given by the equation

$$F = \frac{H^2}{16\pi} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

Now "Regulus" wants an electromagnet designed which will exert a repelling force of 4oz. We must, therefore, first convert the ounces to dynes: 1oz = 28·35 grm. and 1 grm. = 981 dynes. ∴ 4oz. = 4 × 981 × 28·35 dynes = 111,250 dynes = F. We have now to find the flux which will bring about this repulsive force.

$$\frac{H^2}{16\pi} = 111{,}250. \quad \text{Taking } \pi = \frac{22}{7} \quad H = \sqrt{\frac{111{,}250 \times 16 \times 22}{7}}$$

$$= 2{,}100 \text{ lines.}$$

This gives us the maximum value of the flux, and as we generally make our calculations in mean value, we will convert it to such.

Mean ordinate of sine curve = $\frac{2}{\pi}$ maximum ordinate,

mean value of flux = ·636 × 2,100 = 1,336 lines.

We must remember that the flux density we have obtained is the actual flux cutting the conductor. Now, in this question the conductor is situated ½in. away from the magnet, and we shall, therefore, have to introduce a sort of leakage coefficient, because it will be seen that all the lines of force generated by the electromagnet do not cut the conductor. This is illustrated by Fig. 1. We have

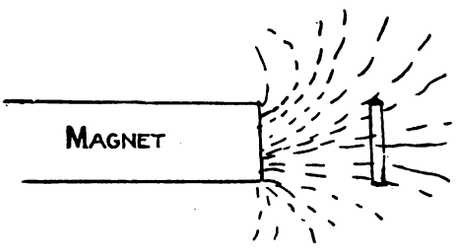


FIG 1.

now to decide the value of this "leakage coefficient," which is

$$\frac{\text{Number of lines generated by magnet}}{\text{Number of lines passing through conductor}}.$$

It will be very large indeed. It will depend on the length of the magnet, as with a long magnet the lines will spread out more in the air in order to return to the other pole of the magnet. It will also depend upon the flux density. I do not know of any definite data on the subject, but I suggest taking it with a fairly long magnet as 10. I do not think this is by any means too large. We therefore have to generate a flux of 1,670 × 10 = 16,700 lines.

Now, the intensity of the magnetic field down the middle of a solenoid of length $l$, having S spirals, carrying C amperes, with an iron core, and the permeability of the iron at this stage of magnetisation is $\mu$, will be given by

$$B = \frac{4\pi}{10} \frac{SC}{l} \mu.$$

Now, as we want a flux of about 16,700 lines, we obtain by referring to permeability curves that for this flux $\mu$ is 320 with soft annealed iron.

$$16{,}700 = \frac{4\pi}{10} \frac{SC}{l} \times 320 \qquad \frac{SC}{l} = 42 \text{ (taking } l \text{ as 20cm.)}$$

$$SC = 840 \text{ ampere-turns.}$$

Therefore, if we construct a solenoid having 100 turns and carrying 8·4 amperes, we shall obtain a flux density of 16,700 lines per square centimetre, and this, as shown above, will exert a repelling force on a conductor placed at a distance of ½in. away from the end of the magnet, of 4oz. per square centimetre.—ELECTRON.

*Answer to No.* 760 (*awarded* 5*s.*).—The formula given for the pull on a mass of iron in a magnetic field is—

$$\text{Pull in dynes} = \frac{B^2 A}{8\pi} \text{ dynes,}$$

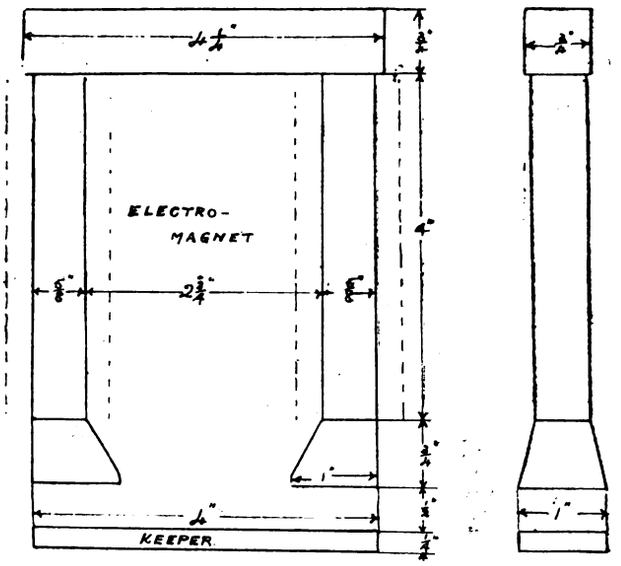
where B = lines per square centimetre entering iron, A = area of iron affected. If, however, we are given the induction in lines per square inch and the area in square inches,

$$\text{Pull in lbs.} = \frac{B_l{}^2 A_l}{10^6} \times \cdot 014.$$

The method of designing an electromagnet to comply with the given conditions is as follows: A weight of about 4oz. is to be suspended. We may take it that one cubic

Digitized by Google

inch of wrought iron weighs ¼lb. Therefore, our weight must be of a volume equal to one cubic inch. As shown in the sketch, it is tentatively made 1in. × 4in. × ¼in. It is



now proposed to make the weight itself—that is, the piece of wrought iron—be the keeper of the electromagnet which is to be excited by the single-phase current. As a preliminary the sizes given are taken, and a design based on them is run through. Should the result be unsatisfactory, the design would have to be modified to remedy objectionable features.

1. *Calculation of Number of Lines entering Keeper.*—

$$\text{Pull on keeper (lbs.)} = \frac{2\,B^2\,A}{10^6} \times \cdot 014.$$

(Note there are two air-gaps)—*i.e.*,

$$\frac{1}{4} = \frac{2\,B^2 \times 1}{10^6} \times \cdot 014.$$

Whence $B^2 = 8{,}900{,}000$, $B = 3{,}000$ lines per square inch, say.

Take a leakage coefficient of 1·5. Then flux through electromagnet = 1·5 × 3,000 = 4,500. This, of course, is the average flux passing through the magnetic circuit. It is assumed that the flux follows a sine law (in the same way as the E.M.F. current). The average flux $= \frac{2}{\pi}$ maximum flux = ·636 maximum flux. Obviously, therefore, the maximum flux may be calculated by multiplying the average flux by $\frac{1}{\cdot 636}$ (= 1·57). Then we get for the magnetic circuit—

| — | Flux (total). | | Average density of flux lines per square inch. | | Length of circuit. | | Max. flux density. |
|---|---|---|---|---|---|---|---|
| Armature ... | 3,000 | ... | 12,000 | ... | 3½in. | ... | 18,840 |
| Two air-gaps | 3,000 (each) | ... | 3,000 (each) | ... | 1in. | ... | 4,710 |
| Magnets..... | 4,500 | ... | 15,000 | ... | 14in. | ... | 23,550 |

2. *Calculation of Ampere-Turns.*—Now the ampere-turns per 1in. of length in magnets and armature may be taken to be equal to 4 (from curves). Also ampere-turns for two air-gaps: ·3133 B $l$. (B = induction in and $l$ = length of air-gap) = ·3133 × 4,710 + ½ × 2 = 1,476. ∴ total ampere-turns = 4 × (14 + 3½) + 1,476 = 1,546. These are what might be termed the (maximum ampere) turns. If we take the virtual value of the current to be $= \frac{1}{\sqrt{2}}$ maximum value, we have for (virtual ampere) turns $\frac{1{,}546}{\sqrt{2}} = 1{,}100$ say.

*Adjustment of Coils.*—It is supposed that the magnet is to be made to take up about 30 volts (that is to act as a choking coil to a certain extent), and as it will form an inductive load, the number of turns necessary to give a back E.M.F. of 30 volts must be calculated. Now the inductive E.M.F. of the magnet will be $= \frac{4\cdot 44\, n\,.\, f\, N_m}{10^8}$ where $n$ = number of turns, $f$ = frequency of alternating current, $N_m$ = maximum flux through magnet. As no value for $f$ is given, a periodicity of 50 is assumed, and therefore

$$30 = \frac{4\cdot 44\, n \times 50 \times 23{,}550}{10^8}. \quad \therefore n = 573.$$

The number of turns are taken at 600, and a current of two amperes is assumed. (Thus ample allowance for regulation will be obtained.)

For the magnet winding a No. 18 S.W.G. wire is used of cross-section = ·001809 square inch, of diameter (over double cotton covering) = ·059in., and having a resistance of ·00034613 ohm per inch. Hence about 4½ layers are needed on each limb of the magnet, 300 turns being wound on each. The resistance of the wire comes out at ·6716 ohm. Hence E M.F. to overcome ohmic resistance = C × R = 2 × ·6716 = 1·343 (The back E.M.F. voltage has been increased in the ratio $\frac{600}{573}$, but there is still sufficient margin below 350 for regulation purposes).

Power wasted by $C^2$ R loss in coils = $2^2$ × ·6716 = 2·68 watts. Assuming 1·75 watts lost in hysteresis and eddy currents, we have total waste = 4·43.

The coil area comes out at 30·5 square inches. ∴ watts to be dissipated per square inch $= \frac{4\cdot 43}{30\cdot 5} = \cdot 15$. This is well within the limit. If an excessive value had been obtained, a new design would have had to be made, altered in some way from the original in order to reduce the amount by increased surface.

As a practical check, it will be noticed that the current density in the coils is 1,100 amperes per square inch; a very fair value.—T. T.

[Other replies to Question No. 760 will be given in our next issue.—Ed. *E. E.*]

## *RE* QUESTION 755.

Sir,—Kindly express my best thanks to "B. W. X." for his friendly criticism and correction. The mistake was due to careless wording; the sentence should have read: "Allowing for all losses, this gives us 35ft. per second as the velocity of the steam and hot gases inside the chimney." Had more data as to the plant been available, I should have also considered the plan of gradually reducing the area of the exhaust pipe from the base of the chimney to its discharge. This in itself would have increased the draught, but as no data was given in the question as to size of pipe, quantity of steam, or back pressure, I deemed it advisable to show the exhaust pipe with a free discharge.—Yours, etc., W. T. W.

## REVIEWS.

**Experimentelle Elektrizitatslehre mit Besonderer Berucksichtigung der Neueren Anschauungen und Ergebnisse.** By Dr. Hermann Starke, Privatdozent au der Universitat, Berlin. B. G. Teubner, Leipzig.

Besides describing the more important experiments conducted in the electrical laboratory and lecture-room, this book introduces the modern theory of electrical science. In a work of this kind it is impossible to be entirely original. Much ground has of necessity to be covered which has been traversed before, and the main points of difference are style and relative clearness of exposition. As regards the latter point, we have no fault to find with the book before us. The author has succeeded in writing down to the level of his audience, a task which some writers with similar ends in view have found beyond them. He uses none but elementary mathematics, and his methods of illustrating well-known phenomena bear the resemblance of originality at times. The book possesses the further advantage of being up-to-date. Thus sections are devoted respectively to wireless telegraphy, Röntgen, Becquerel, radium, and polonium rays, etc. No doubt the work will be found a welcome addition to the text-books intended for German students, especially as it is from the pen of one so able to impart his knowledge to others.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

769. In a variable-speed motor the speed variation, say from 1 to 3½, is effected by varying shunt excitation by resistance in circuit. Auxiliary coils are placed between shunt coils and are in series with armature. In other respects the machine is connected as a long shunt motor. The machine is sparkless from no load to full load at all speeds, and at all speeds on reversal, with fixed brushes, the output remaining constant. Explain theory of sparkless commutation and influence of auxiliary poles on same. At certain low excitations, if the brushes were shifted 1mm. in the backward direction the motor ran away (hunted), and got up an abnormal speed in a second's notice. Explain this peculiarity.—AUXILIARY.

770. In installing boiler feed pumps in generating stations the present-day practice seems to be either a direct-acting steam pump, giving a slow-speed highly efficient pump but a wasteful system of driving, or an electrically-driven three-throw high-speed pump, giving an economical method of driving but a wasteful type of pump, generally driven through two reduction gears. How is it that a combination as described under is not used—viz.: slow-speed electric motor coupled by worm gearing to a slow-speed (2-10 double strokes per minute) three-throw pump, thus giving economy of driving and economy in pumping, worm gears at present obtainable being of high efficiency and large ratio?—W. T. W.

### ANSWERS.

*Question No.* 762.—A three-wire feeder, ·25, ·125, ·25, which under ordinary circumstances carries 180 amperes, has developed a fault on the + side, and now takes only 80 amperes, the − side taking the same amount as before the fault occurred. The feeder is on the same 'bus bar as other feeders, and feeds into a network box 60 yards from switchboard. The fault is between network box and switchboard. Is there any means of locating same without breaking up the ground? as to do so would be very inconvenient, the feeder crossing a busy thoroughfare. The feeder is laid solid in iron troughing, and is free from earth faults.

*Answer to No.* 762 (*awarded* 10*s.*).—The question does not state whether the cable is concentric, three-core, or three single cables, but probably the latter is the case. The feeder being only 60 yards long, it is unlikely that the fault, the nature of which is an increase by about 100 per cent. of the resistance of the positive cable, is in a joint due to bad sweating, or the use of a corrosive flux, but it is probably due to corrosion having set up owing to some foreign substance in the insulation of the cable, or the surrounding bitumen. The corrosion is evidently not due to moisture, as there is no earth fault, but it is extremely probable that the insulation resistance to earth is rather low at this point.

Now if the only fault is an increase of resistance, it is impossible in its present state to find where this extra resistance has crept in; therefore, the best plan appears to be to break down the insulation, which will no doubt happen at the fault. To do this, earth one side of a generator, and couple the other end to the faulty length of main through a light fuse, and run up the machine until it attains its maximum voltage. If this does not break it down, an attempt should be made to disturb the fault by the passage of a heavy current. This is best done by short-circuiting all three cables at the far end (see Fig. 1) and coupling the positive to one pole of the dynamo through an ammeter, A, and the negative and neutral to the other. The station end of the negative and neutral is also earthed through a low-reading ammeter, *a*, and a light fuse, F. The generator is now separately excited and run up dead slow (possibly a water resistance may be necessary to keep the current within reasonable limits) until the current reaches about 500 to 1,000 amperes. After a time the fault will probably burn out, and in doing so earth itself, in which case a reading will show on ammeter *a*, or the fuse will blow.

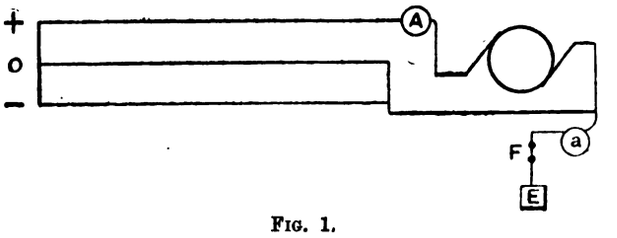

FIG. 1.

In the case of three single cables laid solid in iron troughing, this will probably result in the positive main earthing itself on to the troughing without contaminating the other cores, in which case the ordinary loop test is applicable, and as this has been frequently described in these columns of late I need not detail it again. If the resultant fault is a short, with or without an earth, the following test is probably the simplest. (See Fig. 2.) A battery of

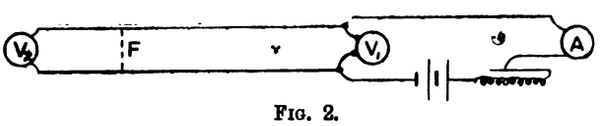

FIG. 2.

two storage cells in series with a regulating resistance and an accurate ammeter reading up to 15 or 20 amperes is coupled across the two short-circuited cables, and two accurate low-reading ammeters, such, for instance, as are used for taking the voltage of individual cells of a battery, are coupled across either end. The current is adjusted to give suitable readings on the voltmeters, and at a given signal simultaneous readings of A, $V_1$, and $V_2$ are taken. Then resistance of cable + fault $= \frac{V_1}{C}$ and resistance of fault $= \frac{V_2}{C}$. $\therefore$ Resistance of length of cable up to fault $= \frac{V_1}{C} - \frac{V_2}{C}$, whence the distance of the fault can be calculated by knowing the resistance per yard of the cable. This should be checked by taking readings from the other end.

If the attempt to disturb the fault has resulted in burning the cable asunder, the above test may still be applied with the following variation. Take readings $C_1$ and $V_1$ with battery, ammeter, and voltmeter at one end, and then $C_2$ and $V_2$ from the other end. Let $R_1$ and $R_2$ be the respective resistances (unknown) of the cable from either end to the fault, and $R_F$ resistance of fault.

Then
$$\frac{V_1}{C_1} = R_1 + R_F \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and
$$\frac{V_2}{C_2} = R_2 + R_F \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$\therefore \frac{V_1}{C_1} + \frac{V_2}{C_2} = R_1 + R_2 + 2R_F \quad . \quad . \quad . \quad (3)$$

$R_1 + R_2$ is the resistance of $60 \times 2$ yards of ·25 cable, and hence the value of $R_F$ can be found from equation (3); and by substituting this value in (1) and (2) we can find $R_1$ and $R_2$, and hence the position of the fault.—H. J.

*Answer to No.* 762 (*awarded* 7*s.* 6*d.*).—When a fault of the type suggested in the question develops, one of two things may be wrong with the cable—*i.e.*: (1) a bad joint has been made, and the exposed metal has afterwards

Digitized by Google

corroded, thus increasing the resistance of the cable; (2) the cable has been laid in such a manner that some part of it has been in a state of stress—this has caused the copper to crack, and thus a *partial* break in the cable has resulted.

The first thing to do is to make a close examination of all the joints in the cable, and if any corrosion or other defect found it must be immediately remedied and the subsequent effect on the working of the feeder noted. Failing any defect in the joint, the fault in the feeder must be due to a partial break. Now, I think it is obvious that it is impossible, in the existing state of affairs, to directly locate the fault, as no matter where it is situated in the cable, the capacity resistance, etc., of the cable will still remain unaltered. The only way to locate is to pass a large current through the cable and thus burn out the fault. This, of course, will burn through the insulation to earth, and then ordinary methods of locating the fault can be used. First disconnect the cable, preferably, of course, during time of light load, so that the other feeders feeding on to the network can easily supply the demand without a great drop in pressure. Now earth the end of the cable at the junction box, making a good connection. Then plug the other end of the cable on to a spare set of 'bus bars, and make a good earth connection from the neutral bar. Now plug a standing shunt-wound generating set on to the same set of 'bus bars, as shown in Fig. 1, with all the resistance in the field circuit. Then run the set slowly up to speed.

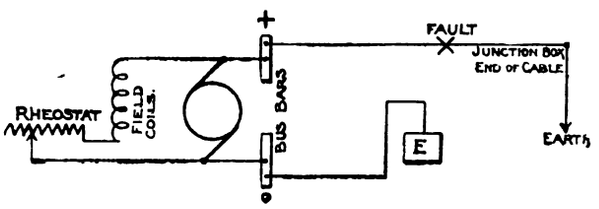

FIG. 1.

If the resistance in the field circuit be large, little voltage will be generated, but in any case watch the feeder ammeter closely until about 80 amperes are passing through it, then slowly increase the voltage generated by reducing the resistance in the field circuit. If there is a circuit breaker in the generator circuit, it will be as well to set it as near as possible to the point at which it is expected the cable will break down—say, 150 or 200 amperes. Then, of course, the current will reach such dimensions that the fault will burn out to earth. The circuit breakers on the machine will come out, or, if there is not a circuit breaker, owing to the exceedingly small voltage being generated—say, 20 or 30 volts—the field of the machine will die down, and it can be shut down. Now, if we have an earth fault developed on the cable it is comparatively an easy matter to locate it. Disconnect the cable from all the previous connections.

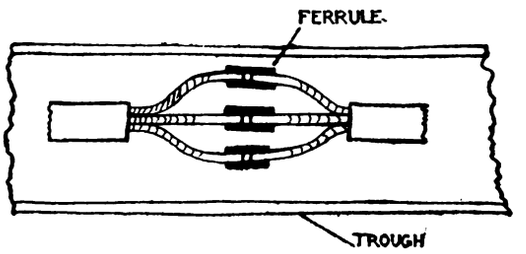
The best method of localisation of the fault is the induction method. An alternating or interrupted current is passed through the faulty cable, the circuit being completed through earth. A coil, in circuit with which is a telephone receiver, is taken over the route of the faulty cable, starting from the point at which the testing current is applied. In a successful test the receiver beats steadily until the point of the fault is reached, when the beating dies away owing to the testing current going to earth.

I will refer the reader to the paper on "Localisation of Faults" by Mr. W. E. Groves, read before the Institution of Electrical Engineers, Birmingham Local Section, Jan. 16, 1904, where a full description of this test and the apparatus is given. There are, of course, many other tests, such as the "loop" test, which may be used, but this one is generally found very successful indeed.—ERNEST P. HOLLIS.

*Answer to No.* 762 (*awarded* 7*s.* 6*d.*).—As this fault is a very curious one, it would be best to prove that the short length of positive cable mentioned is the cause of the trouble. This can easily be done by disconnecting the positive and negative ends of the cable at the switchboards and at the network box mentioned, and cross connecting them. The negative cable, which is of the same section as the positive, would now be taking the place of the supposed faulty section of positive cable. If the original load of 180 amperes is now shown on the positive feeder ammeter, while the negative only shows 80 amperes, then this 60 yards of cable in question is faulty. If, however, only 80 amperes is shown on the positive meter, then some change in the outside load is responsible for it.

Supposing that the fault is proved, it remains to find out what kind of a fault it is, so that some method may be used of locating it. Test the insulation resistances between the positive cable (60 yards in question only) and the neutral wire, positive cable and negative wire, positive and earth; preferably the iron troughing the cable is laid in. If the cable has had an earth or short-circuit on it, the fault will have burnt itself clear. It is possible that somewhere in this 60-yard length of cable the original fault, having burnt itself clear, has reduced the section of the cable and thus affected its resistance. Let us suppose the network is supplied by two sets of feeders and that the resistance of the positive cable in one set is increased. Then the positive cable of the other set would supply a larger share of current to the network, and relieve the first-mentioned positive cable of part of its load. To find out whether this is so, disconnect the set of feeders in question, bridge across from the neutral to the negative cable in the street box, and test the resistance of the two cables from the switchboard. Then, using the same clamp, connect the neutral to the positive cable and test the resistance of these two cables. As the positive cable is of the same area as the negative, and the neutral cable and connections were included in both tests, the resistances should be the same in each case if the positive cable is unaffected by the fault. When the above tests have been made, something definite will be known about the cable. If the cable has a fault to earth, neutral, or negative cable, it can be easily and accurately determined by means of a loop test. A good, practical method of taking this test was described recently in this paper in reply to Question No. 735. If the cable has been injured by a fault which has burnt itself quite clear, then the only thing to do is to dig the cable up.—W. A. T.

*Answer to No.* 762 (*awarded* 5*s.*).—The fault in the cable mentioned is not of the kind most commonly met with—viz., faulty insulation. The fact that less current flows with the same drop of potential along the positive conductor shows that its resistance has increased, owing, probably, to a reduction of its cross-section in one or more places. Two cases similar to the above came under my notice a short time ago. In one case, one of the outers of the feeder, nearly a mile long, was first found to carry about half the current it used to, the remainder being distributed among the corresponding outers of the other feeders in parallel with it. On the following days the current gradually fell off, and ultimately dropped to zero. On testing the affected outer of the cable, the conductor was found to be discontinuous, the cable being otherwise satisfactory. The fault was found to exist at one of the joints, which was of the kind shown in the sketch.



A gap of about $\frac{1}{4}$in. was left between the ends of the cores, and a ferrule slipped over them, the spaces between the cores and the ferrule being made solid by running in solder. This kind of connection may be very unsatisfactory. If the ferrule be too large, and either core not projecting a sufficient distance inside the ferrule, and due care not exercised to fill up properly with solder, the resistance of the joint may be high enough to cause heating, resulting in the solder running out of the ferrule. If the joints be buried in bitumen untaped, as was done in the above instance, the bitumen may flow into the space

Digitized by Google

originally occupied by the solder. Thus, in time, the two cores may become insulated from each other.

The cable referred to by the querist, being a short one, may be in one length, in which case one may be justified in suspecting the joints at the street-box or switchboard end. On the other hand, if a joint exist along the length of cable, and is of the kind mentioned above, I should expect, as the result of my experience, to find the fault there, after making sure of the connections at each end.—H. J. W.

*Question No.* 763.—What are the advantages of the Alberger or barometric type of condenser over other types commonly in use?

*Answer to No.* 763 (*awarded* 10s.).—In order to compare the barometric type of condenser with the various other types in use, it will be necessary to just briefly glance at the main types found in practice. Condensers may be divided into two main classes, in which (*a*) the condensing water and the steam intermingle and (*b*) the condensing water and the steam are kept entirely separate. The first class may be sub-divided into (1) parallel-current jet condensers; (2) counter-current jet condensers; (3) barometric condensers; (4) ejector condensers; and the second class may be sub-divided into (2) surface condensers; (3) evaporative condensers.

*Parallel-Current Jet Condensers.*—In this condenser, shown diagrammatically in Fig. 1, the steam and cooling water flow

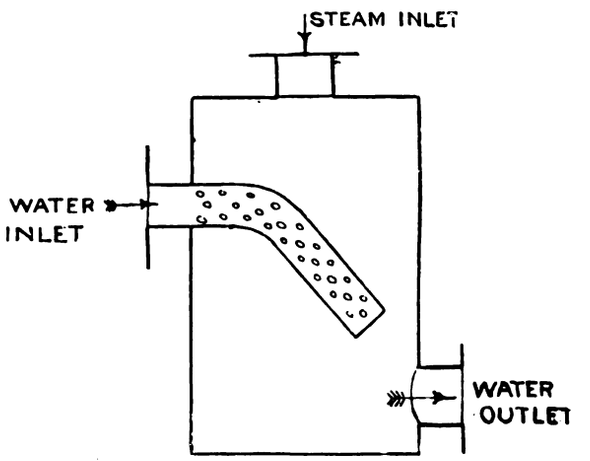


FIG. 1

into the upper end of the condenser, and are, generally speaking, withdrawn by one wet-air pump from the lower end. This type will be recognised as the one largely adopted in slow-speed stationary engine practice. This type of condenser has for several reasons been preferred to the surface condenser for land service; simplicity of construction and comparative smallness of first cost largely account for this. Further, other conditions being suitable, the jet condenser is more efficient than the surface condenser, and gives feed water for the boilers at a higher temperature in the hot-well.

*Counter-Current Jet Condensers.*—In this condenser, shown diagrammatically in Fig. 2, the water and steam inlets are separated as far as possible, the water being withdrawn by a separate water-pump and the air by a dry-air pump. This type, although foreshadowed by Watt, has only been developed commercially during the last few years, notwithstanding that it possesses advantages in economy, in construction, and motive power, as well as in efficiency. As has already been said, the dry-air pump in this type of plant draws its charge from the top of the condensing chamber at a point adjacent to the cooling water inlet, whilst the exhaust steam enters the chamber low down and near to the outlet of the cooling water. Baffle plates are arranged in the interior of the condenser to ensure the complete mixing of the steam and water; air and uncondensed vapour as they rise meet water increasing in coldness, until at the point of exit they are at the temperature of the incoming water. At this point, also, the air pressure is highest, the air denser, and therefore the air is greatly reduced in volume. The saving in volumetric capacity of the air-pumps due to this arrangement, as compared with those required to produce equal results in the ordinary parallel-current jet condenser, is as much as 40 per cent. As the duty of these pumps is simply to compress air, the expenditure of power will also be reduced in the same ratio. Hence with this system, using pumps of equal volumetric capacity, a higher vacuum may be obtained, or for a given vacuum smaller pumps may be employed.

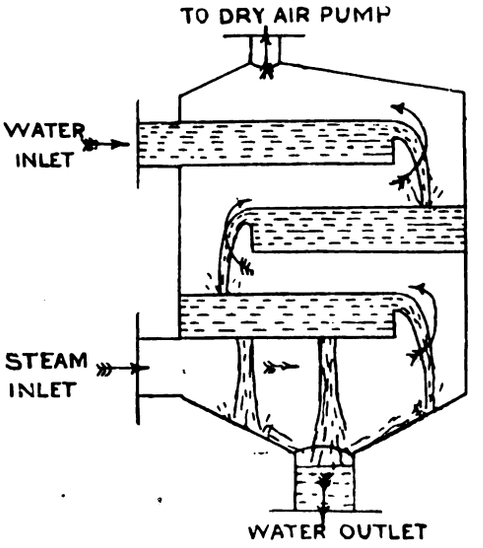

FIG. 2.

*Barometric Condensers.*—The use of the barometric condenser, in which the cooling water mixed with the air and uncondensed vapour is discharged through a column 33ft. to 34ft. in height, is common in connection with industrial installations where boiling and evaporating *in vacuo* are effected under low temperatures. It is not often that a simple barometric condenser is used in connection with a large power plant. Fig. 3 shows one of the simple barometric condensers installed at one of the Manchester electric lighting stations. The exhaust steam enters

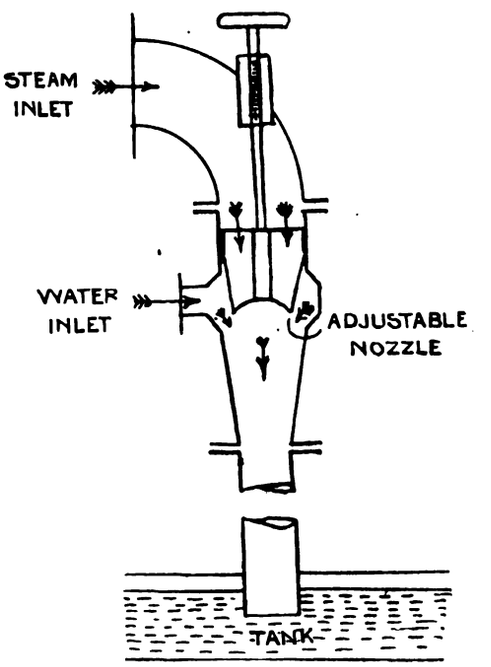

FIG. 3

at the top and passes through a taper nozzle which is adjustable vertically. The injection water enters at the side and passes through an annular space which can be varied in size by moving the nozzle, thus regulating the water supply to the quantity necessary to produce the best vacuum. It will at once be noted that no air-pump is used, and that if the water can be obtained with a head of about 15ft. above the inlet, no pump of any sort is required. But usually the water has to be raised some distance, and to overcome the friction in the pipes and the difference in pressure between the condenser and atmosphere, a centrifugal pump is inserted in the injection pipe. This pump has only to deal with cold water, whereas with

Digitized by Google

counter-current jet condensers the water-pump has to withdraw the hot water from a space which is already highly exhausted. Great care is needed in designing these pumps to prevent lodgment of air in either suction or delivery passages. The water being hot and under such low pressures gives out much air, which must be completely expelled at every stroke, or the pump becomes inoperative. With the simple barometric condenser a vacuum of 26½in. to 27in. can be obtained. Much better results may be obtained with the arrangement sketched in Fig. 4, which shows a counter-current barometric condenser in combination with a dry-air pump. This arrangement combines the advantages of the barometric and counter-current jet condensers without their defects and limitations. At Neasden power-house barometric condensers are employed in conjunction with two-stage dry-air pumps—*i.e.*, pumps in which one pump is used to exhaust the clearance space of the first—and centrifugal pumps on the injection pipes, and should give exceptional results.

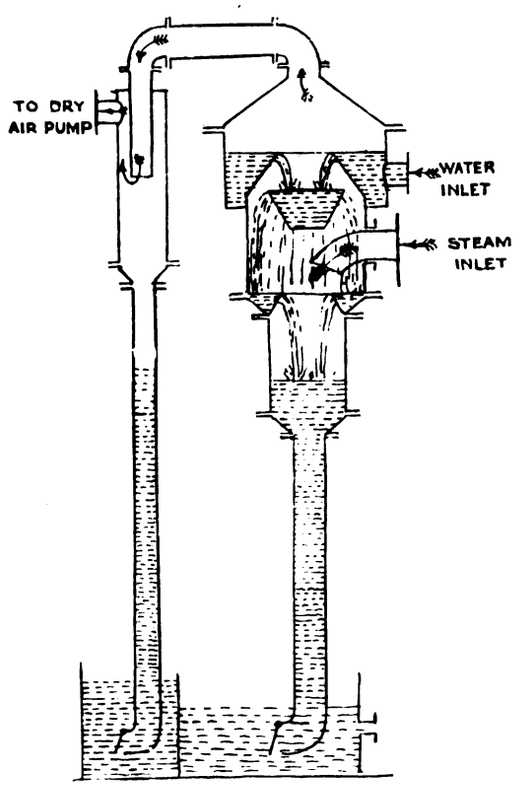

FIG. 4

*Ejector Condensers.* — The endeavour to obtain the simplicity and cheapness in first cost and working of the barometric condenser without its limitations, has produced the ejector condenser in its various forms. In this type of condenser the atmospheric pressure is overcome by the great velocity attained by the cooling water due to a certain pressure head and contraction in area of the supply pipe. The air, vapour, and water of condensation are withdrawn by a stream of water operating as a simple water-jet pump. Fig. 5 shows diagrammatically Korting's ejector condenser. The velocity of the outflowing water prevents the ingress of air from outside, and so a short discharge leg and a water seal alone are required on the outlet side. As water passages are fairly large, very impure water can be used without detriment. The vacuum is, however, rather low—about 25in.

*Surface Condensers.*—In the ordinary form of surface condenser the steam is led into a closed chamber containing a large number of tubes through which cooling water is passed (Fig 6). The tubular condenser in its simple form is rather inefficient, owing to the want of intimate contact between the water and steam, a large quantity of the water flowing placidly through the tubes, absorbing scarcely any heat. On board ship, where the necessity of providing water for feed purposes of a different quality to that available for cooling water is an important factor, the surface condenser must be employed. Much ingenuity has been expended on devices for increasing the efficiency of surface condensers, which are far too numerous to mention here.

*Evaporative Condensers.*—Generally these consist of stacks of cast-iron pipes with conducting fins throughout their length, erected in the open, and having the cooling water distributed in a thin stream over the whole surface. The heat of the exhaust steam is expended in evaporating this film of water, and when the conditions are favourable a satisfactory

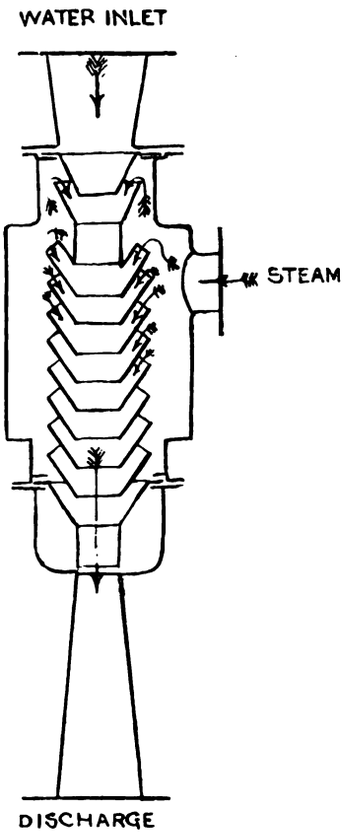

FIG. 5.

vacuum is obtained with the use of a quantity of cooling water even less than that of the steam condensed. Two conditions are essential to success: (*a*) that the numerous pipe joints subject to atmospheric pressure are kept tight; (*b*) that the cooling water, on being evaporated, leaves behind it no incrustation which will act as a non-conductor. The latter is the more serious difficulty in plant of this kind,

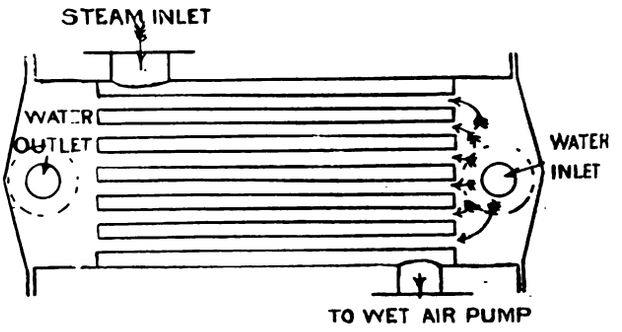

FIG. 6.

and really stands in the way of its more extensive development; otherwise it has much to recommend it. The first cost is not high. The fact that it can most effectually be placed on the roof gives the advantage of a barometric discharge for the water of condensation; hence only a dry vacuum pump is needed to maintain the vacuum in the condenser, and the quantity of cooling water required is so small that, even if it has to be raised a considerable height, the power expended is very small.—H. E. H.

[Other replies to Question No. 763 will be given in our next issue.—ED. *E. E.*]

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

### QUESTIONS.

771. What is the cause of the difficulties experienced in regulating voltage on a two-phase alternating system supplied through three-core cables, and having a partly inductive load? Are these entirely absent on a four-core or double-concentric system?—THREE-CORE.

### ANSWERS.

*Question No.* 763.—What are the advantages of the Alberger or barometric type of condenser over other types commonly in use?

*Answer to No.* 763 (*awarded* 10*s.*). — Before discussing the peculiar advantages of the barometric condenser

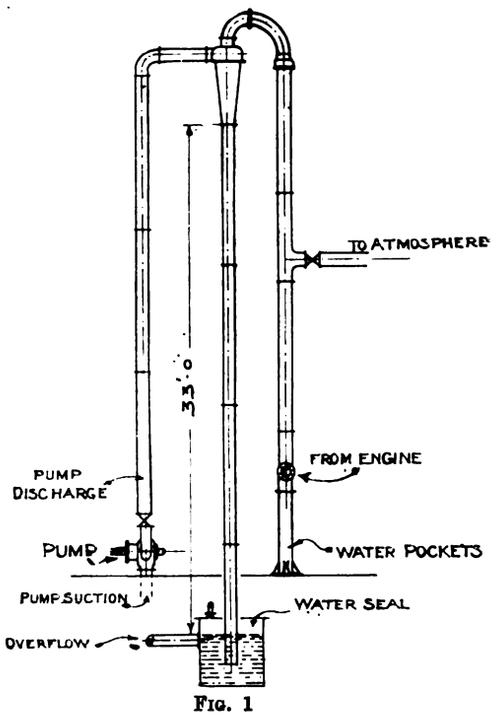

FIG. 1

it would, perhaps, be as well to briefly consider the principles of its working. The whole arrangement is very simple, and is shown in Fig. 1, which nearly explains itself. The exhaust steam from engines is carried up to the top of the condenser head, where it is condensed by jets of water; the whole mixture then falls down the barometric column into a water-tank, where it is taken away by an overflow pipe. Fig. 2 shows a section through a very simple type of condenser head, but which, nevertheless, has proved itself efficient even on a large scale, being quite capable of maintaining a vacuum of 26in., and using 28lb. of condensing water per pound of steam. The jets of water are inclined at an angle of 60deg. to the horizontal, and the water enters at rather a high velocity, thus effectually sucking all the air in the steam with it down the barometric column. If a higher vacuum is required, a small dry-air pump is fitted to suck the air out of the space above the jets. A centrifugal pump is used to lift the condensing water into the condenser. It has to be made large enough to be able to deliver full bore of water if there is no vacuum at the top, but, of course, much less power is required when the plant is running and there is a vacuum. It will be seen from the foregoing description that the great advantage of a barometric condenser is its simplicity, there being no troublesome air-pump with its initial cost and upkeep expenses. Of course where suitable feed water cannot be obtained cheaply, a surface condenser must be put in, but where a form of jet condenser can be used the barometric type will generally be worth consideration. Now a word on the disadvantages of the barometric plant. Special means must be provided for draining the exhaust pipe. Water cannot run down into the condenser as in the ordinary jet, which is generally placed low down, and, of course, the water cannot be drained away direct without first destroying the vacuum. One method used to overcome this difficulty is to fit a water pocket at the bottom of the exhaust pipe. From this pocket a drain pipe is taken to a closed reservoir, the top end of which is connected through a small pipe and cock to the vacuum space. The condensed water then drains down to this reservoir. When full it is cut off completely from the exhaust range, its top end opened to atmosphere, and the water allowed to drain away. Apparatus is made to do all this automatically. Accidents have occurred through water getting from the condenser into the engine. The most frequent cause of this is the water seal at the bottom of the down comer getting broken by the water level falling through some cause or other. Large bubbles of air then rush up the pipe and

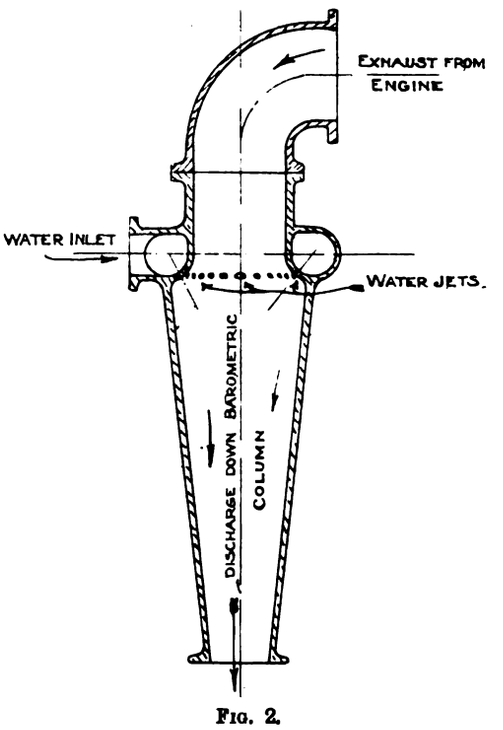

FIG. 2.

drive some of the water in it over the bend. Mishaps of this or a similar nature have prejudiced some engineers against the barometric condenser, but, in the writer's opinion, when carefully designed, the plant, under suitable conditions, is most satisfactory, being cheap and reliable.—E. J.

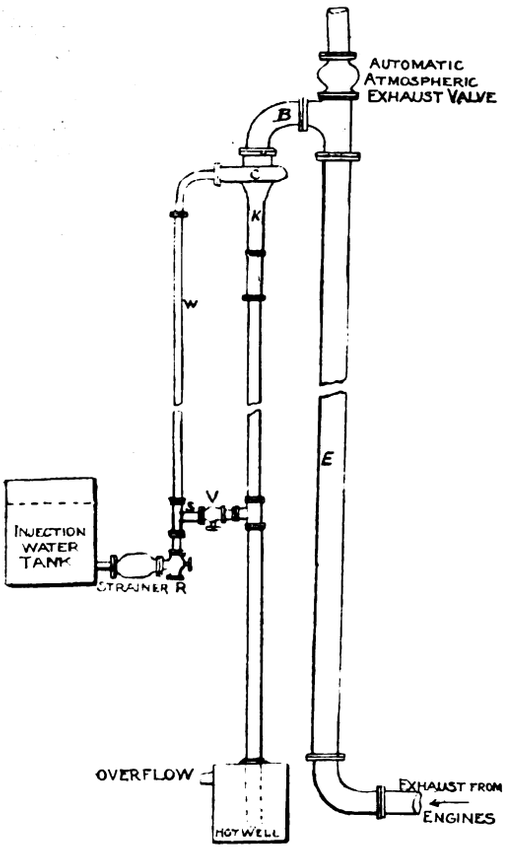
*Answer to No.* 763 (*awarded* 7*s.* 6*d.*).—The accompanying sketch shows a well-known form of barometric condenser; an examination of its properties will bring out its points of advantage. The exhaust steam from the engines passes up the vertical pipe, E, round the bend, B, into the vertical down-pipe, in which the condenser, K, is placed. The injection water enters a cone, C, at the top of the condenser, and has imparted to it a rotatory motion. The exhaust steam entering the top of the condenser comes into contact with the water and is condensed, the resulting water falling with the injection water down the discharge pipe to the hot-well. This discharge—or barometric—pipe is of length sufficient to support the water column by the atmospheric pressure, and is at least 30ft. from hot-well overflow to condenser.

The figure shows a practically automatic type of condenser, in which the injection water is siphoned from a tank, and this can be done if the water-supply level is not

Digitized by Google

less than 10ft. above the hot-well overflow. To start the condenser, a cross pipe, S, is provided, and the starting valve, V, opened until the vacuum is sufficient to draw the water up the pipe, W, and maintain the siphon. The valve, V, is then shut, and the injection supply regulated by the valve, R. If the head of water is less than 10ft. above the hot-well overflow, a pump must be provided to lift the injection water. Once started, this type maintains a steady and high vacuum with less water than the ordinary type of injection condenser. It is reliable in its action, easily started, simple, has no wearing parts. It is easily erected and requires no special foundations; it may be placed outside a building, and thus requires but little space. Its upkeep is practically nil, and cleaning is a small item. It requires no attention when once started.

In comparing the qualities of different types of condensers, the question of boiler feed necessarily enters, but if it be merely a matter of condensation and apart from the ultimate use of the condensed steam, the comparison is straightforward. Surface condensers entail the use of air and water pumps, and the consequent maintenance and attention. The tubes require frequent cleaning, and an

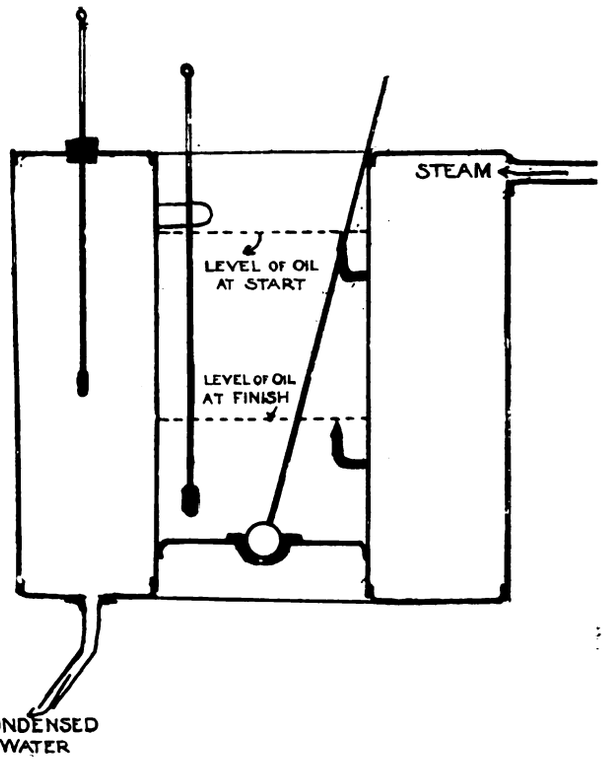


accident to air or water pump means that the plant is out of action. The floor space is considerable, the pumps at least having to be, so to speak, housed. Injector condensers of the ordinary type require an air-pump, and consequently, but to a lesser degree, the remarks made under the heading of surface condensers apply. Ejector condensers cannot be termed economical. They do not produce high vacuums—except under very special conditions with excessive water supply—and are not steady in their action. The above remarks would seem to claim that the barometric condenser is economical, simple, durable, and practically self-acting.—S E. T.

*Question No.* 764.—Give a few simple yet reliable methods of testing cylinder and other lubricating oils, so that a poor consignment may at once be "spotted."

*Answer to No.* 764 (*awarded* 10*s*).—Oils may be classified under the following headings: (*a*) mineral oils, and (*b*) animal and vegetable oils. The former belong mainly to a series of chemical bodies which contain only hydrogen and carbon. These are chemically inactive, and are therefore very suitable for lubricating purposes, as they do not attack the metal with which they must come in contact, and are not acted upon by air or steam. The most elementary member of this series of chemical compounds to which the mineral oil belongs is a gas, namely—ordinary marsh gas. The more complicated members of the series are more or less volatile liquids, comprising naphtha, petrol, kerosine, and paraffin. The higher members are the thick oils used for lubricating purposes, and the very highest are solids such as vaseline and paraffin wax. Many different degrees of oils are contained in the crude mineral form, so that by suitable refining oils of a prescribed consistency may be separated out. The animal and vegetable oils belong to a different class of chemical compounds, known as *glycerides*, and are in general of complicated constitution, and contain oxygen in various proportions and methods of combination. They have the undesirable properties that they absorb oxygen to form gummy viscous fluids, and attack metals to form soaps,* which last process is facilitated by the presence of steam.

The following heads are suggested on which lubricating oils should be tested: (1) viscosity at the temperature at which they are to be used; (2) uniformity of chemical composition; (3) either the flashing point or the volatility; (4) oxidising tendencies due to percentage of vegetable and animal oils; (5) tendency to act on metals owing to similar causes as in (4); (6) presence of mineral matter. Under some of these heads some simple tests can be suggested, but these, as a rule, should not be considered final, but only



as giving indications for further careful investigation, for inasmuch as the adulteration of oils is a specialised scientific process, it requires scientific knowledge and manipulation to detect such adulteration. We will deal with the heads in order.

1 *Viscosity.*—A rough indication of this may, of course, be obtained by shaking the oil in a bottle. A better way is to gauge how long a certain quantity takes to run out of a vessel through a small opening (a pipette would do very well), or again observing the time taken for bubbles to rise in a narrow tube containing the oil. If the same piece of apparatus is always used, a sample sent by the refiners may be taken as a standard, and later consignments should then come up to the same degree of perfection. The viscosity in the case of cylinder oils should be tested at a fairly high temperature, while for bearing lubricants the test should be made at the ordinary temperatures, and then again at about 50deg. C., and there should be no great difference of viscosity in the two cases. The accompanying sketch shows the form of apparatus supplied by several well-known firms for carrying out standard viscometry

* Ordinary hard soap is produced essentially by the interaction of caustic soda and some vegetable oil. In soft soap the metal potassium takes the place of the sodium.

Digitized by Google

tests. The hole at the bottom of the vessel is made through a cup of agate, into which a ball fits to stop the flow of the liquid.

2 The second test is to determine whether the viscosity of the oil has been artificially raised by the addition of solid paraffin, which does not combine, but only dissolves in the oil, and may, under the action of heat, become reduced to a lower member of the series, and thus lower the resulting viscosity of the mixture. Any such alteration of viscosity may have been noticed in (1), but another way is to place a test tube of the oil in a freezing mixture, when the dissolved matter tends to come out of solution. Very thick oils are sometimes adulterated with lighter oils, such as kerosine, and this may, with familiarity with the clear red or yellow tinge of good oil, be detected by the opalescent greenish hue assumed by the oil under these circumstances.

3. *The flashing point* is practically defined by Act of Parliament, and the apparatus for the test has been standardised by the Board of Trade. For our purpose, however, a more satisfactory test may be made by finding the loss in the oil occasioned by free exposure to the air at a fairly high temperature, this, of course, giving an indication of the total volatility of the oil.

4. An oil which is readily oxidised will on exposure to the air form a skin on the surface. As, however, it would be a very bad lubricant with which this tendency was present to any appreciable extent, a more delicate test is necessary. This is to observe any rise in temperature which may take place when moderately dilute sulphuric acid is added to the oil.

5. This is essentially a chemical test. One method of procedure is to place a piece of copper in the oil and leave it for some time. The liquid is then transferred to a separator and shaken up with ether and dilute sulphuric acid. The latter mixture is then drained off, and if any of the copper had been taken by the oil its presence will be shown by the ether becoming blue when ammonia is added. In connection with this test it is a curious thing that animal and vegetable oils, when present in fairly small quantities as adulterations in mineral oils, attack metal more readily than in the pure state.

6. In this test the oil is allowed to burn in a small porcelain crucible, and mineral matter will be left as a residue when all the oil has burned.

In conclusion, it may be pointed out that as no oil is perfect the passing of oils for various purposes becomes, therefore, a question of carefully weighing advantages and disadvantages, and as such requires some little experience.—X Y. Z

*Answer to No.* 764 (*awarded* 7*s.* 6*d.*).—I have bought oils very successfully for many years for my machinery, and have selected from a great many samples. The chief tests I apply are simple and quick, but a little knowledge is more than advisable on the subject. To begin with, let us suppose a cylinder oil is to be submitted. Only samples should be admitted which are suitable for the pressure used in the steam cylinders. If a pressure of, say, 100lb. per square inch of steam is used, then an oil of high flash-point, such as about 600deg. F., should be sought; but with pressures of 50lb. and under a cheaper oil can be used. I prefer a black oil, but some people prefer an oil with a dark-green tinge. For high-pressure steam a pure mineral oil must be chosen, quite free from vegetable or animal or fish oil, as these would be decomposed by the steam. The first thing I do is to take a very little of the oil between my finger and thumb and start rubbing them together. If the oil is good it will work easier as it gets warm, but will not lose its body or consistence, and consequently my finger and thumb will not touch each other. If the oil gets thin and watery, I reject it. I now get a chemical test tube at a cost of 1d., and put oil into it to a depth of 1½in. to 2in., and heat it considerably over a flame. A good oil gets thin and mobile with the heat, but on cooling resumes its former consistency, and is none the worse for the experiment, but a bad oil will crackle and spit as it warms in an alarming way—at all events, at first. Then on cooling it will often show brown lumps, and will even refuse to run out of the tube when it is considerably tilted. Such a bad oil blocks the lubricators, and is apt to be a nuisance. I suppose the brown lumps are more or less adulteration. A good oil will smell the same before and after this experiment, but a bad one will change its odour, and will froth long before it begins to boil. I have given up taking the specific gravity, but I have had good oil at a gravity of 897 and bad oil at ·878. I also have a special bearing which I know is apt to be troublesome, and I put the sample of oil on this, noting how many drops a minute are required to keep it cool, and I find this a very excellent means of comparison.

For an oil to lubricate machine bearings I employ exactly the same tests and ignore the specific gravities, but I have never known any of them turn brown and lumpy by heating. Their chief fault seems to be loss of consistency by rubbing between finger and thumb, and another thing to look out for is a hard watery feeling. Oils with these defects are useless on heavy fast-running machine bearings. The best test, by far, is to put them into a sight-feed lubricator and try them on the special bearing above mentioned, and to note the number of drops used per minute to keep the bearing cool. These oils are generally of a brown or yellow colour, and are apt to be adulterated with paraffin oil to make them thin and cheap, but this "oil" is useless on bearings as a lubricant, and it may be detected by its peculiar blue tinge known as its "bloom," which can be easily seen when the sample is put into the test tube. These oils are also apt to contain vegetable oil, which may be considered a disadvantage, because then they are gummy, and make the bearings, etc., sticky and dirty. Gumminess may be detected by letting the oil flow very slowly down a slightly inclined plane of glass or bright metal in a warm atmosphere, or it may be allowed to siphon over its containing vessel by means of a single strand of worsted, which will become sticky in a day or so if much gumminess is present.

The only other test necessary is to put a bright piece of steel into the sample of oil and leave it there. If the oil is acid, the steel will rust in a few days, and, of course, the oil which rusts the steel will also rust the bearings of the journals, piston rods, cylinders, etc., but it would have to be a very bad sample of mineral oil to behave in this way. As mineral oils have now almost entirely superseded vegetable and animal oils for lubricating heavy machinery, and are cheaper and better, nothing further than that already said above need be mentioned about them. These oils turn rancid and gummy, and should then be refused, because they are acid when rancid, and are dirty and unsatisfactory when gummy.

Any reader wishing to pursue the subject further will find interesting information in the "Questions and Answers" columns of the *Electrical Engineer* for Feb. 28, 1902.—F. G. A.

*Answer to No.* 764 (*awarded* 7*s.* 6*d.*).—Although many ingenious pieces of apparatus have been invented for the purpose of testing oils, they require some considerable experience to get reliable results. The majority of practical engineers either rely on a cursory examination, or, if instruments are employed, they are for the most part of a very simple character. To explain what is meant by a cursory examination, the writer often tastes a sample of oil, by which a fair guess as to its composition and acidity can be obtained. To get an approximate idea as to its "body," take a pinch between finger and thumb and rub together. After a short time oil that is deficient in body will not only lose a great part of its greasy feeling, but may even give a rasping sensation. In order to perform a more satisfactory series of tests, the following are suggested:

*Specific Gravity.*—This very useful test may be taken by pouring some of the oil in a test tube and using a hydrometer. The hydrometer for the purpose should read from ·7 to 1. For very thick oils a specific gravity bottle is sometimes employed. The specific gravity bottle has a glass stopper, through which is a very fine hole; the bottle when filled with distilled water and then carefully wiped weighs a known amount. By filling with any other liquid and weighing, we are therefore enabled to obtain the specific gravity of that liquid. A suitable cylinder oil should have a specific gravity of about ·895, while castor oil is about ·966. Specific gravities of oils are usually taken at 15deg. C.

Digitized by Google

*Viscosity*.—This is sometimes of very great importance. For instance, many otherwise good lubricating oils are so thick that when used on bearings having rotating ring oilers they prevent the rings from turning, thus putting a stop to the flow of oil. A good piece of apparatus with which to obtain the relative viscosity of oils is a glass tube having a small hole at the bottom. The oil drops through this hole, and the time is noted during which the surface of the oil in the tube falls through a certain distance. Another and quicker method is to place some oil in a test tube, and in this place a smaller tube loaded at the bottom. The time taken by the small tube to fall to the bottom of the larger one is then noted, and from this the viscosity is deduced. The temperature must be carefully taken, as oils do not by any means change in viscosity equally with the same alteration in temperature.

*Acidity*.—This is generally found by means of blue litmus paper, but some prefer to note effects when the oil is placed in shallow copper saucers. The latter method will show acidity, if present, by the formation of salts of copper; it will also enable an opinion to be formed of the tendency of the oil to "gum."

*Gumming*.—One method is to measure the distance a drop of the oil will trickle down an inclined clean glass plate in a given time. Another is to place a small weighed quantity in a watch glass, and after, say, 24 hours, weigh again and obtain the loss by evaporation. The tackiness and any tendency of the oil to gum must be carefully noted.

*Flashing Point*.—The temperature at which an oil gives off inflammable vapour is another test. A good cylinder oil should have a flashing point of at least 200deg. C. For delicate tests elaborate apparatus is necessary, but the following will usually satisfy an engineer. Half fill a porcelain crucible with the oil and place over a Bunsen burner, place a thermometer in the oil and note the temperature when the vapour given off by the oil may be ignited by a match. This is, roughly, the flashing point. In order to test the lubricating properties of an oil for journals, etc., some form of testing machine is necessary. One satisfactory contrivance has two discs which may be brought together as desired with an adjustable known pressure. By this means one is enabled to obtain the coefficient of friction of the oil.

As the testing of oils is really a series of comparative measurements, great experience is necessary in order to form correct conclusions, also it must be remembered that an oil unsuitable for one purpose may be particularly satisfactory under other conditions.—M. M.

*Answer to No.* 764 (*awarded* 5*s*.).—Oils used for lubricating purposes may be tested for acidity, viscosity, and solidification.

*Acidity*.—A simple test for this is to take a piece of sheet copper and carefully clean it with fine white sand until a perfectly bright, clean surface is obtained. Now smear the oil to be tested over one-half of the surface of the copper. After a short time wipe off the oil with a clean rag, and note the difference in brightness of the two halves of the copper surface. In order to compare different oils, streaks of oil may be placed side by side on the same piece of copper.

*Viscosity*.—A rough idea of the "body" of an oil may be got by dipping a finger in the sample and "feeling," by rubbing finger and thumb together. The viscosity of an oil may be tested in the following way. Procure a circular vessel, as shown in Fig. 1, about 3in. diameter and 5in. or 6in. deep, fitted with stop-cock, as shown. Suspend across the mouth of the vessel a point gauge having two pairs of points, $a$ $b$, and $a_1$ $b_1$. These points are directed upwards, as shown in the figure. The method of using it is as follows. The cock being closed, and the point gauge in position, a sufficient quantity of the oil to be tested is poured into the vessel to cover the point $a$. The cock is now opened, and the level of the oil falls, thus discovering the points $a$, $b$, $a_1$, $b_1$ in succession. The points will show quite definitely when the oil has fallen to their level. The time, in seconds, is noted between the points $b$ and $b_1$. The points $a$ and $a_1$ are only intended to act as warning points to $b$ and $b_1$ respectively. The test should be repeated a few times and the mean taken. The vessel should now be cleaned out with paraffin oil, and the test repeated, using water as the liquid. The viscosity of the oil compared with that of water will be directly proportional to the time taken in the two cases. Lamansky, in "Dingler's Polytechnische Zeitschrift," gives the following viscosities relative to water:

| Oil tested. | Viscosity (relative) (Water = 1 at 20deg. C). |
|---|---|
| Cylinder oil | 191 |
| Machine oil | 102 |
| Olive oil | 22 |

The Lahmeyer Company make an apparatus for testing the frictional coefficient of different grades of oil at various temperatures.

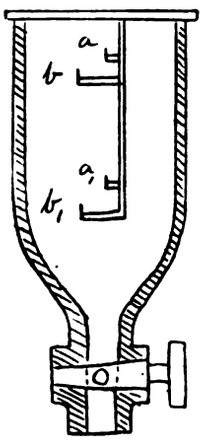


FIG. 1.

*Solidification*.—Take two polished iron plates and lay them together, with a little oil between. Should the oil be liable to solidify it will be found, after a short time, that it is difficult to move the iron plates against one another. If, however, it is found that the oil easily withstands this test, especially after being in stock a few weeks, it will be fairly safe to order the oil wanted.—L. S.

**Electromagnets in the Surgery**.—A writer in the *Scientific American* describes a large electromagnet constructed by him for uses which, save in respect of optical work, appears to be novel. It occurred to Dr. F. M. Wilson, of the Bridgeport Hospital, Conn, that the practice of oculists in using magnets for extracting particles of steel or iron from the eyes might be greatly extended. At his request the author of the article in question designed an electromagnet with a core 4ft. long and 6in. in diameter, insulated with special cartridge paper. A current of 30 amperes at 110 volts has in general been found the most suitable. One end of the magnet is placed in proximity to the part of the body affected, when, as the author naïvely expresses it, "the presence of the piece of steel or iron will be immediately felt by the patient, because of the magnet's attraction." Some remarkable instances of treatment by this method are given, amongst which may be noted a case in which a piece of a hammer-head had been driven into the muscles of the upper arm, and another in which a piece of a chisel had become embedded in the forearm. The surgeons advised no operation, trusting that the pieces would work out of themselves; but, instead of this, the wounds festered, so the magnet was tried. The result was completely successful, the pieces immediately appearing on the magnet. Similar success attended the extraction of a chip of steel that had been embedded in the palm of a man's hand for 1½ years, another piece of steel that had been in the back of the hand for seven years, and a broken sewing needle that had caused much pain. In all these cases the particles appear to have made their exit through the channel by which they entered, and without any surgical operation. The physician has often been aided by electrotherapeutics, and it looks as though magnetism is coming to the assistance of the surgeon. Especially in military hospitals should the new method be of value, in order to remove pieces of shell and steel bullets.

Supplement to "The Electrical Engineer,"
MARCH 24, 1905.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

772. In testing a short length of triple-concentric, lead-sheathed cable with a Silvertown set battery, volts 200, no deflections were obtained on the galvanometer unshunted, ·23deg with 100 shunt through 50,000 ohms. On testing the same cable with an Evershed ohmmeter set, the following readings were obtained: + to −, 40 megohms; + to ⌒⌣, ∞; + to lead, ∞; − to ⌒⌣, 5 megohms; − to lead, 50 megohms; ⌒⌣ to lead, 5 megohms. What is the reason for the differences?—E. H. H.

773. A quantity of lighting cable (200 volts, say) is suspected of being largely composed of reclaimed rubber instead of pure. Is it possible to decide the point, naturally without referring to the makers, and what would be the effect on the cable were such found to be the case?—R. R. R.

### ANSWERS.

*Question No.* 765.—Explain some simple and effective system of recording on which side of a three-wire supply any new consumer must be connected, giving details as to how any probable out of balance may be quickly looked up for any particular district.

*Answer to No.* 765 (*awarded 7s. 6d.*).—The answer to this question resolves itself into the best ways of balancing consumers one against another on a three-wire system, and therefore the methods by which the out-of-balance current flowing into the neutral main can be found at any time on any particular part of the distributing system, with a minimum of time and trouble. In the writer's opinion it is advisable to have at each feeding point a feeder pillar standing above ground, with 'bus bars inside, off which are tapped the various distributors through switch fuses of the Bates type, the middle wires of the various distributors being brought on to the neutral 'bus bar through links. In this pillar, on the back of the marble panel, can be placed a maximum demand current indicator, or a recording ammeter with a plug which can be connected in series with any one middle wire of any distributor in place of its disconnecting link, and thus the out-of-balance current will be registered continuously. The instrument can also be connected in series with any + or − outer of any distributor, and in this way it is easy to find the amount of out-of-balance current on any side of any length of distributor main, and so arrange consumers to the best advantage (see Fig. 1).

There is another way of finding the out-of-balance current, and that is by substituting for the ordinary middle-wire link (and for the outer links if thought desirable) in the distributor disconnecting boxes a special link with a known resistance. This link has at either end small holes, into which are plugged a special portable direct-reading ammeter, so calibrated in regard to the link (which is practically a shunt to the instrument) that it reads direct in amperes the current flowing through the link. The so-called ammeter is, of course, in reality, a milli-voltmeter, as it records the drop across the link at varying currents, but it is calibrated to read the amperes flowing upon which the drop depends. This instrument can readily be used at any disconnecting box, and gives the out-of-balance current flowing at the time. I believe this idea is patented by Mr. Cooper, of the Reading electricity works (see Fig. 2).

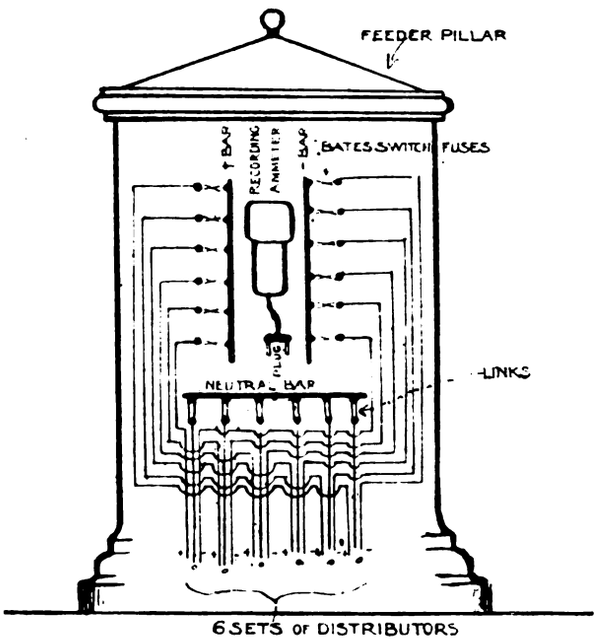

FIG. 1.—The Recording Ammeter can be plugged into any circuit (pos., neg., or neutral) in place of a switch fuse or link.

It is useful to keep at the station a large plan of the whole of the district (fixed on the wall for easy inspection), and have each consumer marked on same with the number of 8-c.p. lamps installed, those consumers on the positive side marked in red and those on the negative side blue.

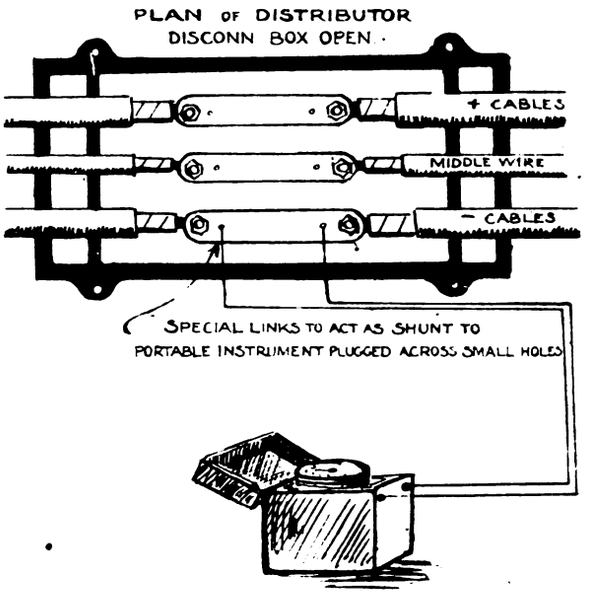

FIG. 2.

It is then easy to see how many lamps are connected on each side of the system on any particular distributor, and gives an indication of the side to connect future consumers.—DUPLICATOR.

*Answer to No.* 765 (*awarded 7s. 6d.*).—In connecting consumers to a three-wire system, it is necessary to give careful attention to the local balance in each street, otherwise there might be large local out-of-balance currents, causing bad regulation, when the balance recorded at the generating station is very good. To obtain good results, it is necessary to balance against each other those consumers having the same class of business. It would be very inferior practice to balance hotels against shops, or churches against

Digitized by Google

street-lighting. To keep a check on the local balance, the writer recommends a system of diagrams, which enable the mains superintendent to see at a glance the probable local conditions in any street and the side of system to which any new consumer should be connected. The local balance diagram book is ruled as shown in Fig. 1. It has a page for each street and for each side of streets where mains run along both sides. Each page of this book has diagrams for different classes of consumers, as shown. It may be divided into as many classes as the user finds convenient. The thick lines denote perfect balance in each class; out of balance to the positive side is set off above, and to negative side below them. As all consumers are liable to overlap on winter evenings, a diagram showing the effect when all are on together is drawn at the foot of page for each street.

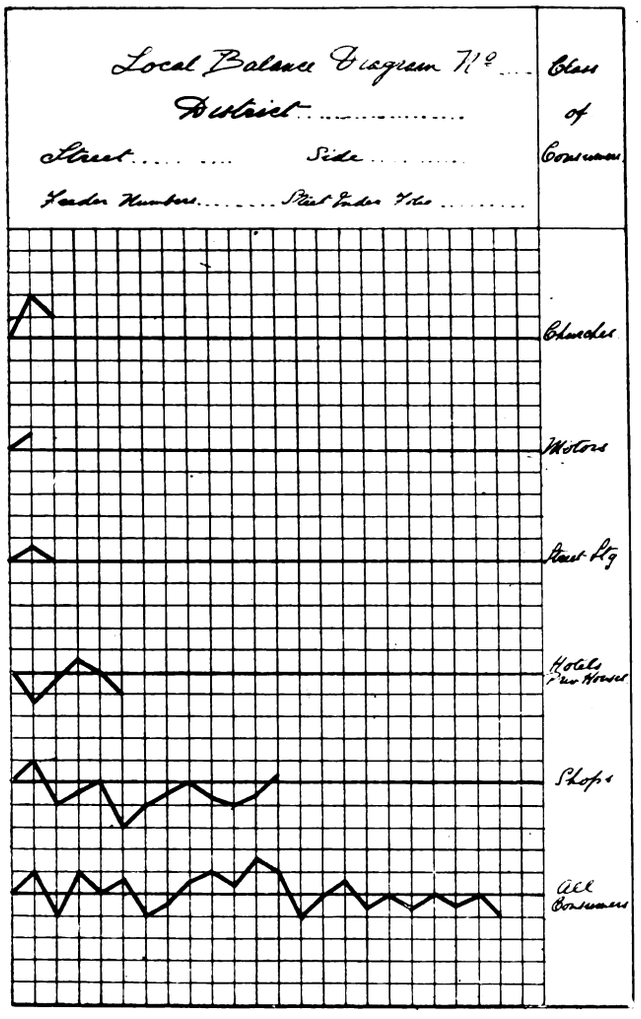

FIG. 1.

To keep the balance on the whole system good, another set of diagrams for each class of consumers should be kept, with every consumer in the area of supply entered thereon, and one showing the effect when all consumers in the area are on at the same time. The object in view when following these diagrams is to keep the out of balance for each class of consumer, both locally and over the whole system, as small as possible, and to so arrange it that when the loads overlap the out-of-balance currents due to different classes of consumers neutralise each other. The method of working is as follows: When a new consumer—say a shop—is to be connected, the mains man turns up the diagram for the street in which the connection is to be made, and looking at the diagram for shops, at once sees whether the out of balance is to positive or negative side. The new consumer is connected on the side that will improve the balance, and a line drawn on the chart for shops, showing the effect. At the same time a line is also drawn on the chart showing the balancing of shops over the whole area, and on the charts showing local out of balance, and total out of balance when all consumers' loads overlap.

To put the diagrams in use for the first time, it is advisable to make out lists of all the connections in each street for each class of consumer, and calculate the probable out of balance for each class. The diagrams are then started from these particulars, a mark being made on each chart. A little intelligent study of the switchboard log will show whether the different classes of consumers are using their lamps in the same proportion to numbers installed on each side of system, and if this is not the case the balance can be altered accordingly.

CONSUMERS' STREET INDEX. No.....

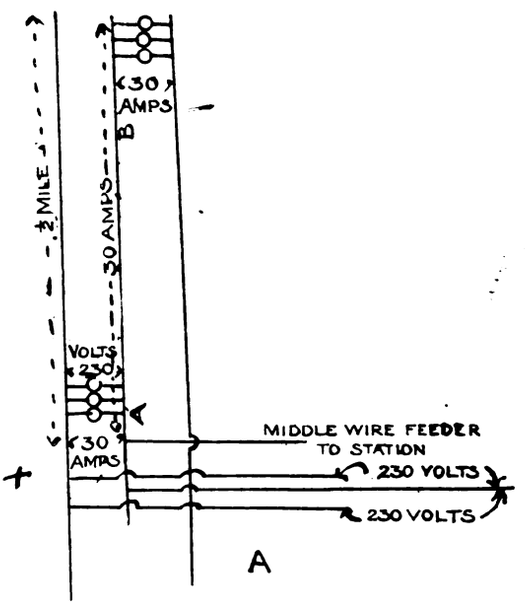
FIG. 2.

In addition to the above diagrams, a book should be kept recording the connections in every street, ruled after the manner of Fig. 2. Apparatus consuming current from the outers should be shown in both positive and negative columns of this book.—T. R.

*Answer to No.* 765 (*awarded 7s. 6d.*).—No hard-and-fast rule can be laid down for equal balancing of consumers on a three-wire supply system, owing to the difference in consumption a consumer is likely to make even if the same class of trade be taken as an example. Your middle-wire ammeter is the best guide to good balancing; by this I do not mean your middle-wire ammeter which is fixed on your station switchboard. By observing this and this alone, you are liable to make serious errors owing to local out of balance, which would not show on this meter provided the sum total was equal on both sides of your system; of course, this would be less marked were you able to plug your ammeter on any individual middle-wire feeder. Let us take, for example, an instance where you are out of balance to the extent of 30 amperes on + side of your network, and 30 amperes out of balance on your − side half a mile lower down. Referring to sketch A, it will be

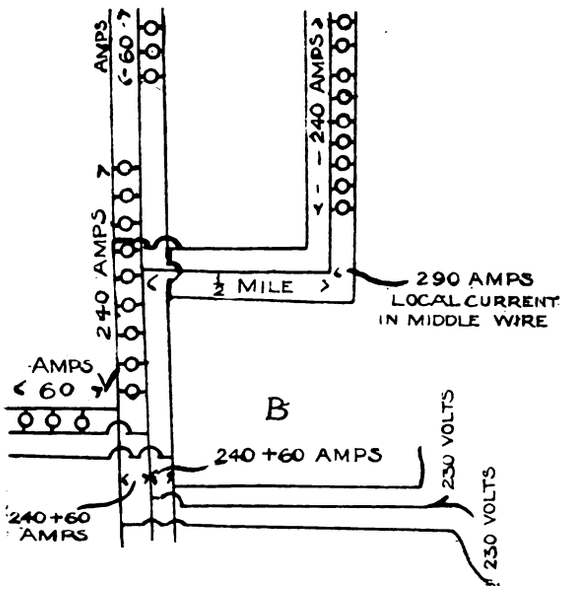


seen that the feeder being on the station side of your network and your pilots as well, no indication of anything wrong would show at the switchboard. The actual state of things would be this: on the + side you would have 230 volts and on your − side 230 volts less the drop in your middle-wire distributor between the point A and B. Sketch B shows a more extensive application of what the writer means.

It is the custom when balancing consumers to have a

Digitized by Google

balancing book which gives you the side any consumer is connected to, which is handy for ready reference, as it is most essential that each street or district should be as nearly as possible balanced on itself. The writer has found it a good plan to put three-wire services in consumers' premises in all districts where a big demand is made. These precautions do not cost much, as I find it little more expensive to put in a three than a two wire service,



and an advantage which far outweighs the convenience, as this comes in not only in the balancing of consumers, but in case of a fault on either outer developing consumers can be changed over till such times as it is convenient to locate the fault.—W. F. S.

*Answer to No.* 765 (*awarded* 5*s.*).—Obviously the best way, or at any rate the simplest method, of ascertaining on which side of a three-wire supply system it is best to connect up a new customer, so as to improve the balance in that neighbourhood, would be to refer to the log book in the station on the switchboard. In this it is usual at stated intervals to jot down the machine currents and also the currents on each side of each outgoing feeder, the out-of-balance amperes on each feeder, the resultant out-of-balance current, various voltages, etc. A little judicious consideration of the position on the network of the new consumer and the out-of-balance currents on the nearest feeder or feeders, will indicate on which side of the system in that neighbourhood is the heavier load, and then naturally the new consumer will be connected on the lightly loaded side. I am well aware that such a thing has been known as the log to be cooked up, but still, even then, the attendant on the switchboard would in all probability have cooked it up, making the general idea as to the load on each side approximately correct.

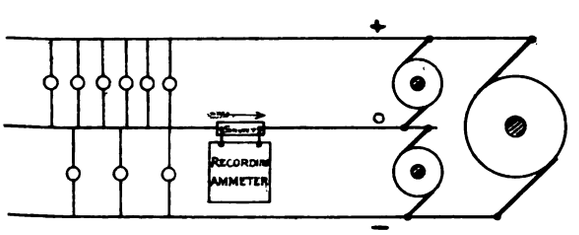


FIG. 1

Another method which could be adopted would be to instal recording ammeters in the neutral wire to show the out-of-balance current. According to how this is connected up, and which side of the central zero the curve usually lies, will be the indication as to which side is taking the bigger current, and then the new consumer should be put on the other side. Fig. 1 will explain the connection of this instrument, and the explanation is this. Suppose the positive side to be taking the bigger current, then the direction of the current in the middle wire will be that shown by the arrow. This current will cause the pen to deflect to one side of the central zero line. If the negative side had been taking the greater current, the direction of the current in the neutral would have been opposite to that indicated by the arrow, and hence the deflection of the recorder pen would have been to the other side.

A third method I should suggest would be to instal recording voltmeters in various parts of the network. These can be had wound differentially with two coils with a central zero, and if connected up correctly the pen will be on the zero line when the voltage is the same on each side of the system. If the pen is not on the zero line, but one side of it, it indicates that on that side of the system there is a greater difference of potential between the outer and the neutral than on the other side. Now, by Ohm's law it can be shown that the side with the fewer lamps on, and therefore the greater resistance, will have the greater voltage across, and hence the new consumer must be connected on the side that has the greater voltage across the outer and the neutral. This matter of the voltage on each side of a three-wire system has been discussed several times lately in these columns, that I think I hardly need go into it once again, but refer "Mains" to my answer to Question No. 745 published in the *Electrical Engineer* for Jan. 6, 1905, wherein I have discussed it fully. Instead of the expense of permanently installing several of these instruments on different parts of the network, no doubt a portable instrument wound and connected in this manner could be obtained. Readings of the voltages at different parts of the network could be taken by a man with one of these instruments at times of the peak load, and these records could be kept for reference, and would be useful at such a time as we are considering. The readings, however, should be taken at points remote from the feeding points, so as to obtain the maximum out-of-balance effects. Readings such as the above might be taken, say, once a month, which I think should be quite often enough.

With reference now to which of the above four methods I think best, I think the last is the best. The first method costs nothing, but only a rough idea can be obtained. The second method, with the neutral-wire ammeter, will also only give a rough idea very similar to the first. The recording voltmeter way is much better, and if enough of them are installed in different parts of the network remote from the feeding points a very definite conclusion can be arrived at. Against this, however, must be put first cost, and the bother of rewinding, inking, etc., of the instruments every day or so, and therefore I should recommend the adoption of the last method indicated with the portable "out-of-balance" voltmeter as being the cheaper and giving the best results.

If it be desired to come to a decision as to which side the consumer is to be put on without the use of any instruments, the best way will be to refer to the large scale map there will probably be in the station showing the positions of all the mains and the consumers. If this be kept well up to date, it may be possible to roughly judge which side is the heavier loaded in any locality, and then the consumer can be connected on the other side.—E. R. ALEXANDER

*Answer to No.* 765 (*awarded* 5*s.*).—The careful recording of particulars about consumers supplied from three-wire systems is most necessary if satisfactory lighting is desired. If the system be not well balanced there will be constant complaints of bad lighting, and consequently the use of electricity will not increase rapidly in the district. Out of

balance may exist which never shows on the feeder ammeters in the station It is advisable at certain periods for the switchboard attendant to take half-hourly readings of the feeder ammeters for a week and lay the results

Digitized by Google

before the mains engineer. He will be able to see in what district and at what time any out of balance comes on, and by referring to the consumer's street index will be easily able to locate the cause of this out of balance, and make a note that the next new customer in a certain class of business must be added to one side of network. A suggested sheet for taking ammeter readings on is shown in Fig. 1, and the consumers' street index kept by the mains department in Fig. 2.

FIG. 2.

The business of the consumer is a very important point to consider. Small workshops require the lights in the early morning, while public-houses, restaurants, and places of amusement late in the evening. Banks and offices only require light during the daytime, and shops until a certain hour in the evening. It would be absurd to connect a public-house to one side of a system and a workshop on the other and expect them to balance each other, supposing them to both require the same current. Each class of consumer should, if possible, be balanced with a consumer of the same class. Of course, premises requiring a large amount of current cause no trouble, for they are internally balanced, being supplied from both sides of the system. Any consumer requiring above 20 amperes should be supplied from both sides of system. It will not be so difficult to arrange consumers in the manner described as appears, for a certain class of consumer is generally found together. In one street there will be only private house lighting, while in another it will be chiefly shops, and so on. If the consumers' street index consists of sheets alphabetically arranged on a file they can be easily referred to, and in the case of much alteration in the arrangements in a certain district new sheets can be prepared to take the place of the old and inaccurate ones.—RESEARCH.

*Question No.* 766.—A central-station engineer of good experience and ability in running steam-driven stations is appointed to take charge of a plant driven by three-crank vertical high-speed gas-engines, direct coupled, and fed from gas producers. What are the chief points he should watch in order to run with the lowest possible amount of coal per unit generated, together with freedom from breakdowns and a light maintenance bill?

*Answer to No.* 766 (*awarded* 7*s.* 6*d.*).—Having held a similar position with same class of engines and gas producers, I mention a few things that it is important to watch.

1. See that your gas producers are kept clean, that they are fired regularly so as to keep the burden at a uniform height, that the peas used are perfectly dry, and that the generators are not blown excessively. Your sawdust in purifying boxes is well if changed once a month, and also clean grids at top of scrubbers weekly; this will enable you to make good *gas*, which, if so, will burn a light-blue colour with slight orange tip at top of flame.

2. Now, *re* your engines, you will be fortunate if you do not at times experience trouble. This may be classed as (1) back-firing, (2) pre-ignition, (3) mis-firing.

Back-firing may be caused by the charge having failed to ignite in the cylinder, and afterwards is exploded in the exhaust by the hot products of another explosion from another cylinder; or that the exhaust valve is not blowing properly, causing part of charge to be pushed by it instead of being compressed, and the explosion then travels from cylinder to exhaust pipe. The remedy for this is attention to ignition to ensure gas charge being properly burnt and attention to valves.

By pre-ignition is meant that the charge is by some means becoming ignited earlier than it is timed to do. This may be caused by the presence of carbon on top of piston block (a common occurrence in this class of engine). This becomes hot due to explosions, and, of course, fires charge too early sometimes. When the charge is entering by way of inlet valve, and often when compression is taking place, you will observe the latter by putting your ear to cylinder and observing a whistling noise, together with a lurch of your engine. The remedy is a clean piston head. Another cause of pre-ignition, and a very important one in this class of engine, is the leakage that often takes place under the seat of cover of inlet valve. When replacing this cover, you must be extra careful to see that the seat is perfectly clean, otherwise you will have considerable trouble, as this explosion takes place in mixing chamber, and at times it contaminates the mixture to the other cylinders, thereby causing a shut-down.

Mis-firing is often caused by failure of supply current. This is best obtained, if possible, from a set of accumulators. Then, of course, the igniters are likely at times to become grounded. This will at once shut your engine down; also the igniter stems require to be kept well ground in to prevent leakage, as if this takes place the stems become hot, causing them to stick. Keep points in good condition. Also, another point to be fully observed when running is the temperature of your engines. This is best at about 100deg. F., as if engine is run too cold sweating takes place, causing various troubles.

With regard to obtaining best results with your charges, this is obtained by firing your engines exactly at the proper time. This is best ascertained by means of indicator and diagrams; at the same time you may judge also the best mixture to use when running under load. The usual time of firing is between 20deg. to 30deg. in advance of crank, and the mixture to use is about 1 of gas to 1·5 of air; this I have found gives good results. *Re* all mechanical work, similar to steam-driven sets in repairs, etc.

In conclusion, I may say if you pay attention to the few points I have mentioned, you will be able to run your station well and reliable and also obtain good results. You will have a freedom from breakdowns and not a very large maintenance bill. As you admit your experience in gas-engines has been rather limited, I would advise you to proceed cautiously *re* making any alterations, and to read up at once any good work dealing with combustion engines in general.—S. H. L.

*Answer to No.* 766 (*awarded* 5*s.*).—In reply to "Silica," the following hints may be useful. First, with regard to the engines. The sparking plugs should be examined daily, and, if necessary, cleaned, as these are liable to get dirty and cause miss-fires. It will also be found that a certain amount of coke dust will be blown through with the gas, which collects on the mixing valve, inlet valves, and on top of the pistons. This should be cleared away about once a week and the inlet valves ground in, or pre-ignitions and back-fires will be caused. Oil in the crank chamber should be kept at a fixed height (the height being fixed by the makers) or it is liable to be sucked into the cylinders, where it gets carbonised and causes pre-ignitions. This oil will probably require filtering about once every three months. The settings of the valves should occasionally be examined, as they are liable to alter, and much trouble has been occasioned by one inlet valve not closing at the proper moment. Of course, there must be a plentiful supply of water to keep the cylinders cool.

With regard to the generators, if clinker is formed, it should be removed daily. The best gas is obtained when a level fire is kept with no holes in it, so that the stoker should bar down about every half-hour. The fire should also be kept as near as possible to one fixed height. With these precautions the writer has obtained as low a value as 1·8lb. of coal per unit generated. The best proportions for the gas are: $CO_2$, 6·8 per cent.; CO, 19·22 per cent; H, 19·24 per cent; O, a mere trace.

If these hints are followed out, "Silica" should obtain good results, with low maintenance and coal bills and few breakdowns.—R.

[Other replies to Question No. 766 will be given in our next issue.—ED. *E. E.*]

Supplement to "The Electrical Engineer,"
MARCH 31, 1905.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

774. In a description of the electrification of a railway in France some weeks ago, rotary converters were mentioned as running compounded with the series windings opposing the shunt. Explain how such machines work, and give any advantages which they possess over ordinary compound rotaries.—G. J. R.

### ANSWERS.

*Question No.* 766.—A central-station engineer of good experience and ability in running steam-driven stations is appointed to take charge of a plant driven by three-crank vertical high-speed gas-engines, direct coupled, and fed from gas producers. What are the chief points he should watch in order to run with the lowest possible amount of coal per unit generated, together with freedom from breakdowns and a light maintenance bill?

*Answer to No.* 766 (*awarded* 7*s.* 6*d*).—It may be assumed that the plant in charge of the engineer is modern, and that the question refers simply to actual running charges apart from any alterations or additions to the existing plant. Considering first the engines, the first point requiring particular attention is the relative volumes of gas and air. If too much air is supplied, the gas drawn in is necessarily too little, and the engine capacity is lowered; if too little air, there is an excess of gas, and thus a surplus unconsumed each cycle, and a consequent loss of economy. It is therefore incumbent that the air supply be so adjusted that the proper proportions of gas and air are mixed in the chambers, and if the gas varies in quality, the proportion of air must also be varied.

Compression and the clearance between cylinder head and piston is the next important point, and the higher the compression, and consequently the smaller the clearance, the more economic is the engine. The most economic compression consistent with safety from spontaneous combustion being arrived at by careful testing, the engineer must see that his clearance is maintained unaltered.

Premature ignition must be avoided, and the igniter must be watched. If electric, a reversal of current periodically reduces the wear on the terminals, and of course, if possible, spare breakers should be installed. The ignition time must be kept correct and constant at the point just when the piston is about to begin its stroke after compression. The exhaust valves must be adjusted to clear the cylinder and close promptly. Naturally, the wear on the main bearings is great and the alignment of the engine and machine bearings should be periodically tested and adjusted. The water supply must be carefully watched and an adequate amount allowed, the cylinder jackets must be efficient. To advise a competent engineer that periodic indication of the engines and analyses of the gas are necessary is superfluous.

The producer plant requires more care than is generally given it—the method of stoking, cleaning out of ashes, and blast being matters of paramount importance. The coal costs depend primarily on the quality and cost of the coal. A free-burning rough slack of only slight caking qualities—not a coking coal—is to be sought, one with 5 per cent. of hydrogen to 60 or 70 per cent. carbon would be good. Ash and moisture to 25 per cent.—if the coal be cheap—is not detrimental, for good gas can be obtained from such a coal. The gas should be clean as delivered to the engines, and care must be taken in such cleaning. Tar must not be delivered to the engines, and the gas should be carefully washed and filtered. Washing must not be done until the gas be cooled—this is done partly by a regenerator and finally in a cooler; coolers and filters must be kept clean. By-products may be worth recovery, and the residues are ofttimes readily saleable. Works costs from three gas-power stations averaging 446,000 units each per annum, and from six steam-power plants averaging 350,000 units, are given below, and it will be seen that while coal and maintenance are nearly equal in the two systems, oil, etc., and wages are higher for gas than steam. Theoretically, coal and wages should be lower for gas than steam, and an up-to-date plant will probably give a reversal of the figures given.

| | Coal. | Oil, etc. | Wages. | Repairs. |
|---|---|---|---|---|
| Gas | ·62*d*. | ·18 | ·46 | ·22 |
| Steam | ·59d. | ·07 | ·38 | ·24 |

—S. E. T.

*Answer to No.* 766 (*awarded* 5*s.*).—It is but a few years ago since engineers, as a rule, only considered the gas-engine as a makeshift for the more familiar and better understood steam-engine; at present, however, the gas-engine is better appreciated. Electrical plants are now run satisfactorily by means of gas-engines, although undoubtedly more care and attention is necessary than when steam-engines are employed. The writer, when first placed in charge of a gas-driven plant, felt very diffident as to the behaviour of the engines, but careful study of their idiosyncrasies changed that diffidence into confidence. Perhaps the recounting of a few of the difficulties that cropped up may be of service to the querist. Without exaggeration, I can say that at least three-fourths of these troubles were caused by faulty ignition. Having had experience with both hot tube and electric ignition, the latter method has proved the most reliable. Taking the hot tube first, in the case of miss-fires it will often be found on examination that the tube is insufficiently heated. The Bunsen burner should be turned up or down as may be required—the flame must be at just the right height in order to secure the maximum heating effect. Another cause of a poor heat is when the tube is not equally surrounded with the flame; this can easily be remedied. Ignition tubes are generally placed inside an iron case, the iron case being lined with asbestos millboard. This asbestos liner must be in good condition or it will be found difficult, if not impossible, to keep the ignition tube at the proper heat. The asbestos must be cut to fit, well soaked in water, and placed while wet inside the iron case; when dry it will be found to keep in its position perfectly. The care spent over fitting a new asbestos liner will be well repaid. When metal ignition tubes are employed, at the slightest sign of fracture a new tube should be fitted or the result may be a stop when under load. If porcelain tubes are fitted, the spare tube must always be kept in good condition. With electric ignition by batteries and induction coil all the parts must be kept in thorough order, and sparking points frequently cleaned. If a magneto is used, see that contact at sparking pin is good, and that the circuit is broken at the proper time, giving a good spark. With both these forms of electric ignition every care should be taken that the insulated wire is in good condition. A point that requires more care with gas than with steam engines, is the lubrication of the cylinders; a good mineral oil, and plenty of it, should be used. Oils that give an appreciable deposit should be discarded. Use fresh oil for the cylinders, afterwards filtering for use at bearings, etc., where the lubrication is not such an important matter as is the case with the cylinder. Such an arrangement will enable the engine attendant to use plenty of oil without making it come abnormally expensive. With some plants, the circulation of water round the cylinder is not all that might be desired; this must be watched, and the pipes kept free from any obstruction. Gas-engines

Digitized by Google

do not generally stand an overload so well as steam-engines; it is, therefore, good policy not to exceed the limit oftener than possible. It will be found better practice to run four units at three-quarter load than three units at full load. There will be little more difficulty in running machines in parallel than if steam-engines were employed, but, of course, more flywheel power is necessary. Gas-engines are sometimes a cause of annoyance by reason of the explosions, but good silencers will reduce this to a minimum. When using town gas precaution must be taken to ensure a good supply; pressure gauges may readily be fitted on each engine. With producer gas the case is more in the hands of the engineer himself, and, given suitable fuel, ordinary care should leave little fear of a "shut down."

With regard to the station cost per unit, gas-engines have several advantages over steam-engines. The stand-by charges are lower, and they show a greater thermal efficiency than steam-engines. Gas-engines, however, unless carefully looked after, are likely to run up a heavy repairs bill, but this again is a point where the ability, or inability, of the engineer-in-charge will assert itself. Generally, the writer is strongly of opinion that where the performance of gas-engines is unsatisfactory, much is to be attributed to the want of skill of those in command. These engines demand greater and more skilful attention than steam-engines, but if that is accorded them, they will do, and do well, all that may reasonably be expected.—M. M.

*Question No.* 767.—An isolated three-wire network is fed from a sub-station by means of 100-kw. continuous-current transformers transforming from 2,500 to 440 volts. Two transformers are running at nearly full load, supplying the load and charging a battery at its normal rate—viz., 120 amperes a side—by means of a balancer booster fitted with shunt and series windings on the balancer fields. The motor and generator windings of the transformers are superposed, the high-tension winding being on the outside. These machines are self-exciting, shunt wound, there being also a high-tension series field for starting up, which is cut out automatically when the low-tension field is sufficiently strong. All machines and the battery are fused at about 200 per cent. overload. Under these conditions, if one of the transformer armatures breaks down from high tension to low tension, what will be the effect inside and outside the sub-station, and what approximately will be the extent of the damage?

*Answer to No.* 767 (*awarded* 10*s*).—The conditions given may be represented diagrammatically as in Fig. 1. It may be assumed that the middle wire of the three-wire network is permanently earthed, and then three principal cases can be distinguished.

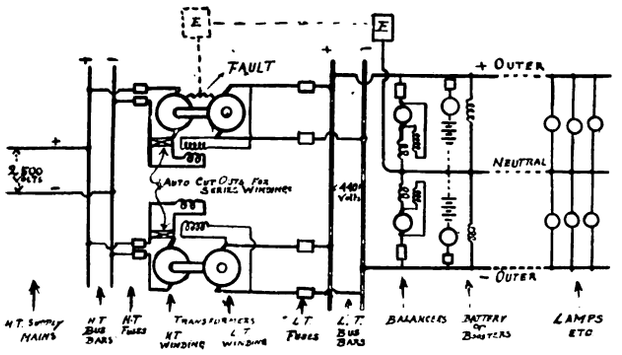

FIG. 1.

1. Should the fault in the transformer armature simply connect the high-tension and low-tension windings without putting them to earth, and should the high-tension supply mains both be thoroughly insulated from earth, no damage whatever need result, although the + and − low-tension outers would be subjected to a strain of $\frac{2,500}{2} = 1,250$ volts to earth (assuming that both high-tension supply mains have equal insulation resistances to earth) in place of their normal voltage of 220 to earth.

2. If the fault not only connects the high-tension and low-tension transformer windings, but also, as would most probably be the case, connects both of them to the armature core and so to earth, an intermittent short-circuit would occur, first on one side and then on the other side of the low-tension three-wire network. Every time the fault came under a low-tension + brush on the transformer the full 440 volts would occur between the middle wire and the negative outer, and at the same time the + outer and the middle wire would be short-circuited together, so that the + half of the battery would pass an excessive current to earth through the fault (see dotted lines in Fig. 1). In this way all the lamps on the negative side, and also the negative battery and balancer, would be subjected to 440 volts in place of 220 volts, and the + battery fuse and the + fuse on the low-tension side of the faulty transformer, as well as the balancer fuses, would be subjected to enormous currents. These effects would only occur intermittently, however, for when the fault arrived at a point midway between + and − low-tension brushes the normal state would again be reached, and, finally, when the fault reached the − low-tension brush the full 440 volts would occur across the + side of the network, whilst the negative outer and the middle wire would be short-circuited. This periodic action would repeat itself every time the fault passed from a brush of one sign to one of the opposite sign. In spite of the rapidly fluctuating nature of this voltage rise and overload, they would very soon lead to the burning out of all the lamps on the system, and the blowing of one or more of the fuses on the battery, balancers, and the low-tension side of the faulty transformer. So far the occurrences are only those which would occur on any ordinary low-tension three-wire supply if one of the main generators developed a fault to earth.

3. If, however, one of the high-tension supply mains (say the negative) is more or less earthed, and the transformer armature fault puts both high-tension and low-tension windings to earth as in (2), every time the armature fault reaches a + brush of the high-tension side of the faulty transformer, the high-tension mains will be more or less short-circuited (according to the quality of the earths on the negative and at the fault), and the high-tension fuses would very soon blow, though possibly not before the excessive current passing through the faulty high-tension winding had caused a flash over from + to − brush, and damaged the commutator and brush gear of that machine more or less. The excessive current passing through the earth on the armature would be sure to necessitate partial or complete rewinding of the armature. So long as the high-tension fuses did not blow, the occurrences described in (2) would also take place on the low-tension side.

In the rather unlikely event of the earthing of the high-tension and low-tension windings at the fault being imperfect, more or less of the full 2,500 volts would occur between the + low-tension outer and earth each time the fault reached a high-tension + brush, and this would probably cause serious damage to the insulation of the low-tension mains, and of the positive balancer and positive booster before the high-tension fuse had time to blow.—Q.

*Answer to No.* 767 (*awarded* 7*s.* 6*d.*).—Fig. 1 is a diagram showing the general arrangement of the connections on the high and low tension circuits, showing one complete transformer circuit, with balancer booster, etc. Under ordinary working conditions a current of about 40 amperes will flow along the high-tension cables, and one of 230 amperes along the low-tension of each transformer. In the event of a transformer armature breaking down from high tension to low tension, this means that the high-tension current has now a circuit of very low resistance to flow in. Consequently we have a very big rush of current taking place caused by this fault. Now, in the case of a fault occurring on a high-tension transformer circuit, it is necessary that the switch controlling that circuit should open automatically. Since the machines are set to 200 per cent. overload, this means that the switch will be carrying over three times its working current, and we shall have the contacts very badly burnt and require renewing. As regards the pressure on this high-tension transformer circuit it will not require to be considered, as since the transformer is running the switch will open the circuit, the pressure across the contacts being the difference between the high-tension 'bus bars and the back E.M.F. of the transformer. If the high-tension generators are working at nearly full load, we may have the extra high-tension current produced, causing the maximum cut-outs on the machines to act,

Digitized by Google

thus cutting out the machine from full load to no load, and probably breaking down the armature owing to the high pressure developed, as well as doing damage to the switch and brush gear. These dangers can to a great extent be overcome by using switchgear of the Ferranti type (Fig. 2), where instead of the circuit being broken on the switch, it is broken by the copper contact, C, on the horns, the arc travelling upwards and gradually dying away.

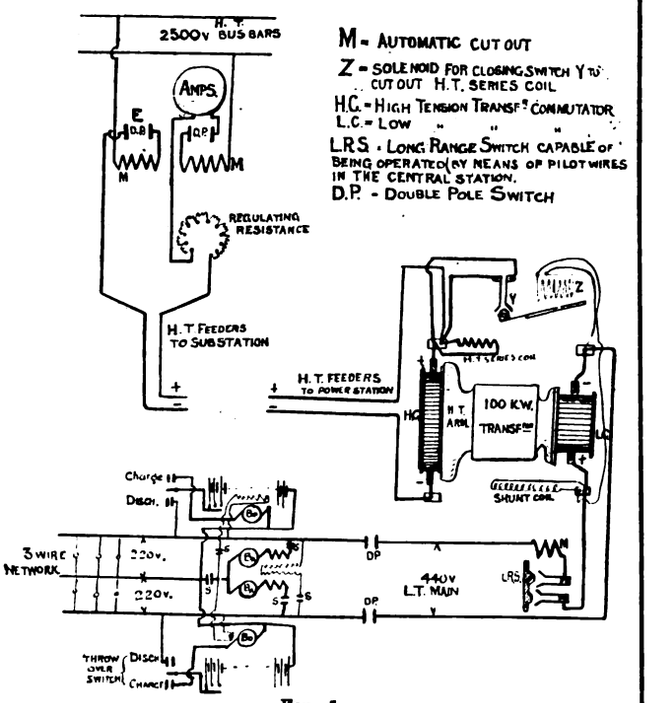

FIG. 1.

Turning to the sub-station, we find that the brushes and commutator on the high-tension transformer are very badly burnt owing to the excessive current (and the armature will require stripping and repairing), and that the pressure on the low-tension armature being practically six times the original (since the high-tension is now connected to low-tension), this without the heavy current may be sufficient to completely break down the insulation and earth it. This may probably be prevented by the maximum cut-out on the "long-range switch" picking up and breaking the circuit, and when this occurs it generally means that new

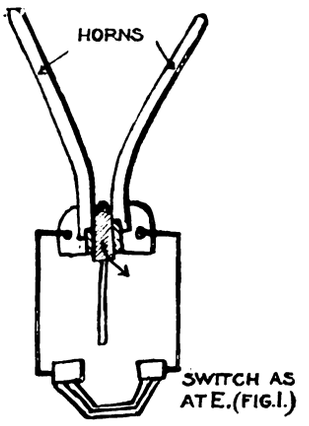

FIG. 2.

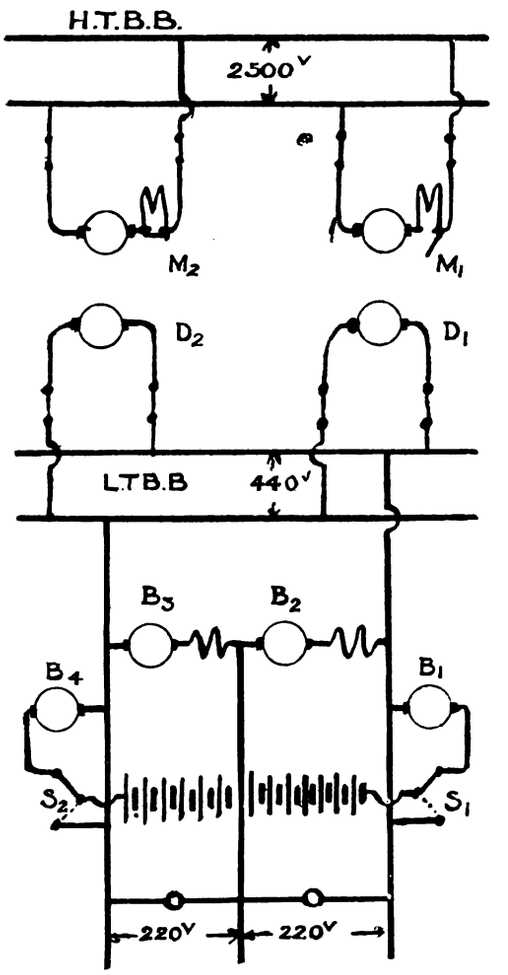
jaws, etc., are required on the switch; meanwhile we have the supply either cut off on the low-tension side (if the other transformer has cut out) or we have the pressure considerably dropped owing to the overloading of the other transformer, and the battery will discharge heavily through the boosters, and probably damage the plates or melt the connecting wires off. A lot depends upon the arrangement of the circuit breakers, as by these being properly set a lot of damage may be prevented, as the writer has known of cases where damage has been done which would not have occurred on later types of switchgear.—L. H.

*Answer to No. 767 (awarded 7s. 6d).*—To enable us to understand fully what is likely to happen under the circumstances mentioned, let us examine the sketch below. $M_1$ and $M_2$ are the high-tension commutators and series windings. The series windings are used in starting-up the transformer from the high-tension side, and when $D_1$ and $D_2$, the generators for the low-tension network, have started generating they are self-exciting, and supply the shunt current which passes through a solenoid, automatically short-circuiting the high-tension series windings. The compound balancers, $B_2$ and $B_3$, besides balancing the network drive the two battery boosters, $B_1$ and $B_4$, which are in circuit at the time, charging the two halves of the battery.

Suppose that the high-tension breaks down to the low-tension winding on No. 1 machine. The high-tension fuses of No. 1 machine would blow. They might blow before any further damage was done to the armature, but the chances are that the arc formed would earth the low-tension windings to the armature core. In the first case



No. 1 machine would probably simply run as a motor from the low-tension mains in the same direction as before. If, however, the low-tension windings were earthed, No. 2 machine and the battery combined would try at all events to blow the fuses of No. 1 machine on the low-tension side. We see that No. 1 machine would now either be running as a motor from low-tension side and giving no trouble, or all its fuses blown, making it completely dead. If the latter, the armature would be a complete wreck, owing to the large current that would flow before the large fuses would blow.

The two battery boosters, $B_1$ and $B_4$, are, or should be, fitted with automatic switches, $S_1$ and $S_2$, so that in case of an accident of any kind calling upon the batteries to discharge, the switch would automatically switch the booster off and drop into the bottom contacts, putting the battery straight on the line. If there is no device of this kind, the current will be flowing in the reverse direction through the battery booster armature, and as the shunt winding will remain the same, the booster will tend to run as motor in reverse direction, whilst the balancers

Digitized by Google

are striving to run in the ordinary direction, with bad results for the battery booster. Besides this, the battery discharge may be so heavy as to seriously heat up the booster armature, which is only designed for a definite charging current. The result of the accident would be that No. 2 machine would be doing all the load, which would only consist of the outside load, as the battery would no longer be on charge, as the booster armature would probably be cut out when the accident happened, leaving the battery straight across the bars ready to help No. 2 machine if the line volts fall low enough.—RESEARCH.

*Answer to No.* 767 (*awarded* 5*s.*).—There is but very little chance of any damage being done by the high tension breaking down to the low, for it is practically impossible for the high pressure to find its way to the low-tension mains—that is to say, the P.D. between the low-pressure mains will always be dependent on $\frac{N n Z}{10^8}$, no matter whether the two windings are in contact or not—where N is the flux passing through the armature, $n$ the speed in revolutions per second, and Z the number of armature conductors in series on the thick wire winding. Imagine one of the high-tension conductors in contact with one of the low, then the whole of the low-tension winding will be raised to the potential of this particular conductor, and the high P.D. will exist, not between the two low-tension mains, but between the high and low. Suppose that two of the high-tension conductors break down to the low in different parts of the armature—a condition that is not at all likely to occur—then it is fairly clear that the high pressure will urge a current round the thick wire winding which will either blow the fuse or burn out the armature, but the pressure on the low-tension side cannot be raised to a dangerous value on account of the low-resistance circuit formed by the thick wire winding. The whole arrangement appears to be good, and there is no cause for anxiety with regard to the high tension breaking down to the low, but it is, of course, advisable to take frequent insulation tests, for the blowing of high-tension fuses and machines burning out are not things that are desired in connection with an electric lighting supply. Also, it should be remembered that if a conductor on the high tension comes in contact with one on the low, the consumer's fittings will have a high P.D. between the high-tension mains, and should there happen to be an earth on the high-tension side, anyone handling the fittings is likely to receive a 2,500-volt shock. A voltmeter or a batch of lamps connected between earth and the low-tension side would indicate when such a condition exists.—E. AUSTEN.

*Answer to No.* 767 (*awarded* 5*s*).—Very little data in connection with the type of switchgear used is given in this question, and therefore only an approximate idea can be given as to the extent of the damage done by the breaking down of high-tension to low-tension windings. We will, however, assume that maximum cut-outs are fitted on the high-tension switches, and long-range switches at the sub-station fitted with maximum and reverse current cut-outs on the low tension. The chances of a high-tension continuous-current transformer (with superposed windings) breaking down to low tension are very small, since so much attention is paid to the insulation between the two windings. I have, however, known one case where this happened, and the result was that the fact of breaking down had burnt the insulation of the low-tension winding, due to the shorting of the adjacent conductors, to such an extent that the low-tension winding broke down to earth. A case of this kind necessitates the rewinding of the armature, unless the fault be at the end of the core, and then may, perhaps, be rectified by splicing, but in any case the steel bands would have to be taken off the armature.

The most frequent trouble with transformers of this system is the low-tension winding shorting or breaking down to earth. One of the worst troubles in connection with the running of these transformers is the sparking and commutation troubles. Now, if only two machines are feeding an isolated network on full load, and one breaks down, it is almost a certainty the other one will suffer when it is called upon to do 100 per cent. overload, and probably do considerable damage to the brush gear, and in some cases have been the cause of breaking other machines down to the earth. This, however, can be greatly eliminated by having automatic devices on the switchgear. Fuses are not to be recommended for any work when this system obtains, as they are the means of fires in many cases, although at the time of the breakdown the balance booster would be charging; the latter is no doubt fitted to operate in such a case, and the battery would take the load from the network. The battery would not, however, last long, and unless some means obtain to connect up to another network, the sooner more plant was got up the better.—G. S.

*Question No.* 768.—It is required to establish telephonic intercommunication between eight huts on the banks of a canal. The huts are a half-mile apart. It is desirable to use as few wires as possible, any reasonable system of signalling being permissible. Can this be accomplished with two or three wires, nine being entirely out of the question?

*Answer to No.* 768 (*awarded* 5*s.*).—I notice that "J. H." asks in this question whether certain telephonic results can be attained by the use of two or three wires, at the same time qualifying this question by stating that it is desirable to use as few wires as possible. I may therefore state at once that all he requires can be attained by the use of one wire only, and in view of the above qualification, I shall not enter into the desirability of employing more than one wire. I have had the same number of telephones that "J. H." requires—viz., eight—working most successfully in this way for the last five years. They are used on an electric power distribution system for which I am responsible. Some of them are in a mine, whilst the others are scattered about, the distance between the two farthest apart from each other being about 2½ miles, though there is no reason why this distance should not be much greater. It will be seen, therefore, that the installation of telephones that I allude to is of nearly the same type as that required by "J. H.," and is used for the same sort of purpose.

The telephones should be of the magneto type, and should all be joined up in series by a single wire, and only the instruments at each end of the line must be earthed. Each station must have its own call signal. Thus the signal for No. 1 may be a single ring; No. 3, three rings; No. 5, five rings; No. 6, two long, two short; No. 7, two long, three short; No. 8, eight rings. This may appear complicated on paper, but in practice it is found to work well, and anybody concerned soon gets to know all the signals. If one station is more important than the others, it will probably be desirable to give it the simplest ring as its call. With this system there can be no secrecy, of course, but probably this is of no practical importance in an industrial concern such as "J. H." mentions. It may even prove an advantage at times, as it is always open for anyone interested to find out what is going on, and so keep himself up to date without necessarily troubling other stations by calling them up. For instance, it often happens in the working of the power plant mentioned above that the engineer is at one or other of the telephone stations and hears another station being called up. If he is interested, he can take the receiver off his telephone without in any way interrupting the other stations, and listen to what is going on. Sometimes he may replace the receiver without remark, or at other times he may break into the conversation with advantage. Again, A may be talking to B and it may be desirable to obtain certain information from C before A finishes his conversation with B. C is called up therefore, and then A and B hear simultaneously what he has to say, and the conversation can be carried on between all three, thereby saving time and trouble.

I may add that on the system I have described above there are two branches, of half mile and 1½ miles respectively (with three telephones connected up), which are not permanently in circuit, but they can be "put through" when required. If "J. H." has any difficulty in carrying out the above suggestion, and will communicate with me, I shall be willing to assist him, if possible.—T. P. O. YALE.

[Other replies to Question No. 768 will be given in our next issue.—ED. *E. E.*]

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

### QUESTIONS.

775. A leading stoker in a certain central station is suspected of inefficiency. How can I tell whether he is getting the full duty out of his working boilers before putting in another on a rising load?—W. E. O.

### ANSWERS.

*Question No.* 768.—It is required to establish telephonic intercommunication between eight huts on the banks of a canal. The huts are a half-mile apart. It is desirable to use as few wires as possible, any reasonable system of signalling being permissible. Can this be accomplished with two or three wires, nine being entirely out of the question?

*Answer to No.* 768 (*awarded* 7*s.* 6*d.*).—The number of ways which these huts could be telephonically connected together by two or three wires are many, but of these we will only attempt two. We will assume that outside line construction is very expensive, and that as satisfactory signalling and metallic circuit speaking can be obtained by the use of only two wires, we will assume that it is decided only to use the one pair.

*Method No. 1.*—This system will no doubt give the most satisfactory signalling with far simpler apparatus, of a type which is much less liable to get out of order than any other. Fig. 1 shows a complete wiring diagram of this system—ordinary simple telephone circuit, including transmitter, receiver, switch hook; induction coil and two dry cells complete the listening and speaking circuit. The signalling circuit only comprises one small type of hand generator, with a single-line plug and two single-line jacks for calling and a 1,000-ohm magneto bell for receiving the signals. The plug and jacks in each station can easily be replaced by a one-lever two-position switch, if that is preferred. The circuit almost explains itself—the method of calling being to insert the plug in either jack according to which station is needed, and then giving the hand generator one, two, three, or four separate turns—that is, No. 1 station can be signalled by turning the hand generator at any other station once with the plug in the right-hand jack; No. 2, by giving two turns; No. 3, by giving three turns; and No. 4, by giving four turns; each turn causing the distinct signal on the bell. In the same way, stations 5, 6, 7, and 8 can be called by inserting the plug in the left-hand jack and ringing the requisite number of times. Of course, before anyone should attempt to ring on a line of this description, they must of necessity take the receiver off the hook and listen to ascertain whether anyone else is using the line, and if they are they must wait until it is clear. This system can be highly recommended, and will not give the slightest trouble after having been properly installed. Of course, the usual precautions must be taken against lightning and foreign currents, but that does not enter with the circuit in any way. The resistance between the lines, as can easily be seen, is 500 ohms, and as all of this is composed of wire wound round iron the retardation effect is very high, and absolutely clear speaking will result.

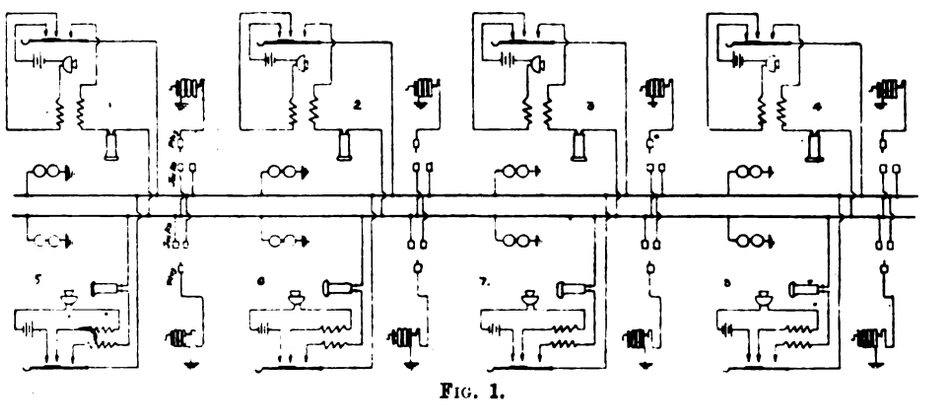

FIG. 1.

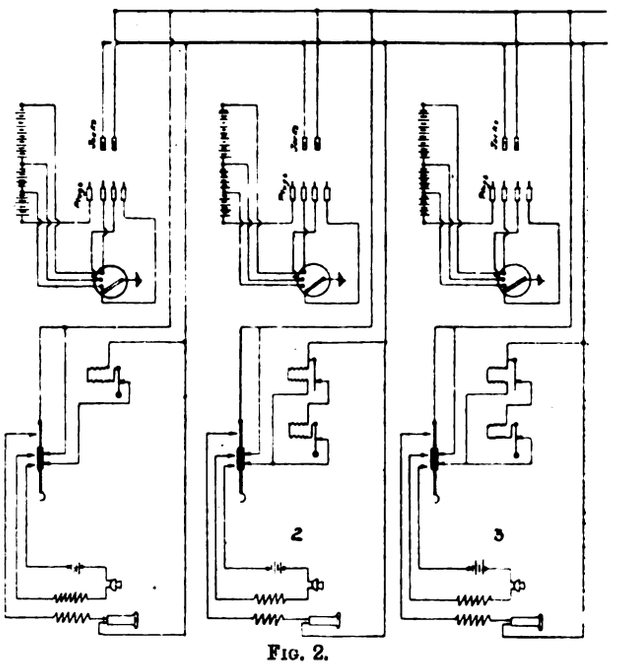

FIG. 2.

*Method No. 2.*—The only real objection that can be raised to method No. 1 is that four bells are rung at the same time instead of any particular one, and although in practice this is not found to have any serious objections, still, a system in which but one bell is rung at once is certainly superior, and we will now attempt to explain a method of connecting up the telephones so that this result is arrived at. Fig. 2 shows the connections of nine separate stations connected up on one pair of lines, and the following explanation will show how the circuit works. The same speaking and listening sets are used as in method No. 1, but the signalling circuit consists of direct-current bells and dry or wet batteries in the place of hand generators. A battery tapped, connected up at the two ends and at two intermediate points so as to give three separate voltages, must be installed at each station, and along with this the complete output comprises one four-point single-lever switch and four single-line plugs, and two single-line jacks must be used for calling. The apparatus for receiving the signals consists of direct-current bells arranged as follows:

*Station No. 1.*—A 1,000-ohm direct-current trembling bell adjusted to work with not less than 24 volts.

*Station No. 2.*—A direct-current trembling bell which will not work with less than 12 volts in series with a cut-off relay. This relay is an ordinary direct-current bell without gong or hammer connected up so as to cut off the current

Digitized by Google

from the bell immediately it operates, and adjusted to work with anything over 20 volts.

*Station No. 3.*—A direct-current trembling bell which will work with six volts in series with a similar cut-off relay to that mentioned in station No. 2, which will work with anything over 10 volts.

*Station No. 4* is equipped similar to station No. 1, except that the bell is polarised and adjusted so that it will work with the same current as the bell in No. 1, but only when the operating current flows in one direction.

*Stations Nos. 5 and 6* are similar to Nos. 2 and 3 respectively, except that the bells are polarised.

*Stations Nos 7, 8, and 9* are exactly similar to Nos. 4, 5, and 6 respectively, except that the bells are polarised to work in the opposite direction.

The method of operation is as follows: To ring stations Nos. 1, 2, 3, battery must be put direct across the line without earthing it and three voltages used respectively. Stations 4, 5, 6 are signalled in a similar manner by using three different voltages, but this time one side of the battery is earthed and the other side is put across the left-hand side line. Stations 7, 8, 9 are called by earthing one side of the battery and putting the other side on to the right-hand side. In a similar manner the same precautions must be taken against lightning and foreign currents. Before signalling is attempted the line should be listened upon to find out whether it is in use or not. The only difference between this method and Fig. 1 is in the signalling circuit. All the bells should be wound with the same resistance, say 1 000 ohms each, the variation in the adjustment for working at the different pressures being obtained by altering the number of ampere-turns and the tension in the armature springs. If the bells are of the above resistance, the fact of putting them across the line will not in any way materially affect the efficiency of speech transmission. This system will cost far more to keep up than in the first case, but with good lines, good installation, there is not the slightest reason why it should not work satisfactorily.

*Note.*—We will assume that the line used is of such a resistance that 8, 16, 32 volts will give satisfactory signals between any two stations, whether adjacent or at extreme ends of the line. The battery power selected may seem rather high, but when one considers that overhead lines are subjected to all kinds of weather and leakage effects, and possibly in some cases rather questionable joints, we think that the voltages chosen are not too high, but at the same time it is quite feasible to assume that with properly low resistance, insulated lines, and carefully adjusted apparatus, the pressures of, say, 5, 10, 20 volts, or even lower, might be used.—C. W. A.

*Answer to No.* 768 (*awarded* 7*s.* 6*d.*).—Before dealing with the above problematical, yet most interesting, question from the standpoint of a solution, or of an attempt at solution, it may be of service if we consider it briefly from the point of view of the information which can be gathered from it. In the first instance, we are given to understand that the establishment of telephonic intercommunication between eight huts situated at equal distances apart from each other, and extending from extreme hut to extreme hut over a total length of 3½ miles of the banks of a canal, is a desideratum. Now, although the question states specifically that the huts are situated on the *banks* of a canal, it does not give any information concerning the relative location of the huts—*i e*, as to the position which each hut occupies with respect to each and all of the seven remaining huts. Therefore it is necessary that some pre-assumption anent this point shall be made.

We will here assume that the huts are situated alternately on the two sides of the canal, for which arrangement see Fig. 1, in which figure $H_1$, $H_2$, $H_3$, . . . $H_8$ represent the eight huts, four being on one side and four on the other. This arrangement, until more definite information is forthcoming, appears, in the opinion of the writer, to be in perfect harmony with the conditions and requirements of the question, and yet is something definite as regards the comparative situation of the huts, which in actual practice is of the most vital importance. Again, there is not offered in the question any light respecting the peculiar conditions of the intercommunications—*i e*, as to whether or not it is required that a person in *any* one of the huts shall find it possible to communicate with another person in another hut, even although at that very moment connection may exist between two other persons who would be in actual communication. It is, however, not probable that the former condition of working will be demanded, because then it would not, with ordinary and *reasonable* telephonic apparatus, be possible to work successfully with a maximum of three line wires; hence we will assume here that the latter is the only possible contingency.

As regards the actual systems of lines, instruments, and connections, it may here be stated that there are several possible solutions to the above query which do not involve the use of nine line wires, but only two, three, and four lines respectively. These systems are, however, potentially and intrinsically different; one system possessing advantages which are the disadvantages of the others, and *vice versâ*. We will here consider the above three systems in the order in which they are arranged.

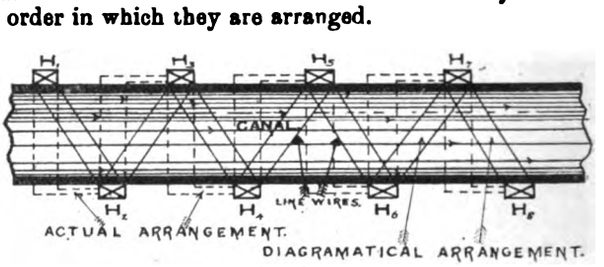

Fig. 1.

*The Two-Line Wire System*.—This system obviously involves the use of only two line wires, one acting as the forward wire and the other as the return wire. But although it possesses distinct advantages in the direction of the number of line wires, it is defective in directions which will be hereafter referred to. And it is on account of these defects having such a great influence upon the efficiency and general workability of the sys em, that only under exceptional and extraordinary circumstances would the writer dare to advise its introduction. In Fig. 2 will be found a diagram of all the necessary connections of the instruments in all the eight huts to accomplish the establishment of telephonic intercommunication between *any* one hut and *any* one of the remaining seven, at one

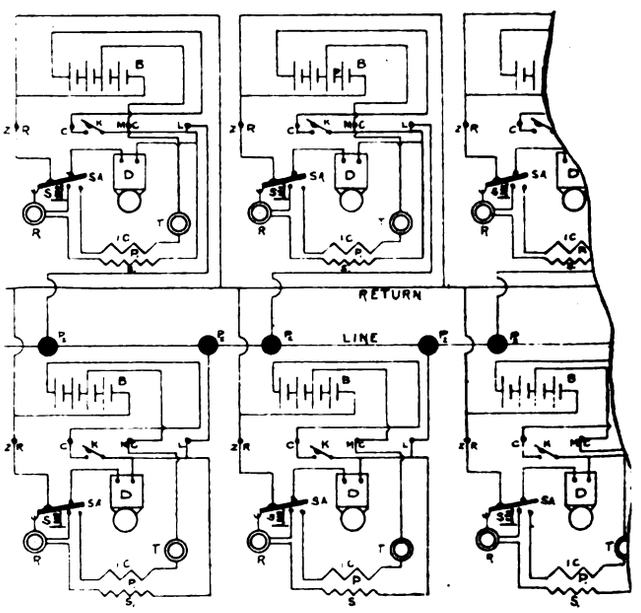

Fig. 2.

and the same time, on this system. On the introduction of such a system the chief difficulties which have to be contended with are those of the simultaneous ringing of the bells of all the instruments, though this may be partially advantageous, and the simultaneous working of all those bells which do not belong to the two instruments in communication during the time of that communication. For reference to Fig 2, the following index of parts may be of service: B is the battery, of about 10 or 12 volts pressure; R is the receiver; T is the microphone transmitter; I C is the induction coil; $P_1$ is the primary of the

Digitized by Google

induction coil; $S_1$ is the secondary of the induction coil; K is the key for ringing up other stations; D is the bell; S A is the switch arm or hook upon which the receiver hangs when not in use; S is the spring to pull S A down to the under-contact studs, when R is lifted off the switch hook; Z R is the terminal connection to the zinc of the battery and to the return wire of the system; C is the terminal connection to the end carbon of the battery; M C is the terminal connection to the middle carbon of the battery; L is the terminal connection to the line wire of the system; $P_2$ is a two-way plug switch (enlarged in Fig. 3), which is introduced into all the eight instruments.

A few words concerning the above-mentioned two-way plug switch will, probably, not be out of place here. From a consideration of Fig. 2 it will be observed that if the plug switch had been omitted in every instrument, it would be possible to ring all the bells of six instruments at once, and yet, at the same time, to speak only with another instrument distinctly and efficiently, the bell of which instrument would, consequent upon the falling of the switch arm, S A, be cut out of action. Now, this unnecessary bell ringing is disadvantageous for two prime reasons—the first, because the batteries will not last so long, having to perform more work, as would otherwise be the case; and the second, because the bell-ringing would develop into a nuisance, and prevent any ordinary conversation being carried in the affected huts. If, however, two-way plug switches are inserted in all the instruments, these disadvantages are palliated, if not entirely removed. When the instrument is not in use the plug is inserted in the *a* position, so that that instrument is connected to the line and return, and that no instruments are cut out of circuit. When one

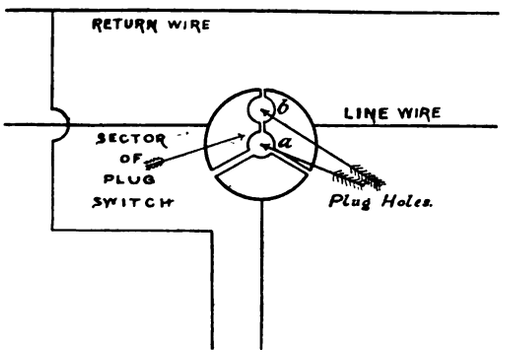

FIG. 3.

instrument is engaged with another instrument, the plug of each instrument which is then non-communicating is moved from the *a* position to the *b* position in order to prevent the continual bell-ringing nuisance. This, too, constitutes a disadvantage, because it can hardly be expected that under the circumstances the use of the instruments will admit of such elaborate manipulation.

The *modus operandi* is now as follows: Suppose that the instrument on the extreme left of Fig. 2 requires communication with the fourth instrument from the extreme left. Then the key, K, of the instrument on the extreme left is depressed, with the result that all the bells are set in action. To indicate which instrument it is required to speak with, a certain number of rings should be given in quick succession according to some prearranged code of signalling. In this case four rings should be sufficient to indicate that it is the fourth instrument which is required. Upon the receipt of the bell signal, every plug should be removed from the *a* position of the plug switch to the *b* position, except in the case of the two engaging instruments, in order to isolate the instruments for the time being and to prevent the continuous bell-ringing. Conversation can then be carried on between the first and fourth instruments without any interference or interruption from any of the other instruments. If a limit of, say, a three or four minutes' converation be imposed, then at the end of the period of the limit the plugs should be reinserted in the *a* position, and when such is accomplished there is no impedance to communication being obtained between any two instruments on the system. Speech on these two lines would probably be fairly satisfactory, but it will readily be seen that much trouble and inconvenience to persons using the instruments would be entailed in the insertion, removal, and reinsertion of the plugs; and if the plug is not in the *a* position, the instrument would not have any line connection, and consequently would not admit of any engagement with another instrument. Hence the whole system is inherently defective, but it is the only system which can be adopted if two-line wires are to be strictly adhered to.

*The Three-Line Wire System*.—This system, as will be shown further on, possesses decided advantages over the two-line wire system. As its name implies, three wires are used in the place of two, as in the previous system, and it is on account of this fact that this system stands in possession of qualities which are absent in the other system. In Fig. 4 there will be found a diagram of all the necessary connections of two of the eight instruments, the connections of all the instruments being identically similar to those of the two represented in the figure, the positions of the instruments making no difference whatever. In this system the defect of the continuous bell-ringing and its attendant nuisance have been obviated and entirely removed. The additional wire is marked "B L wire," and is so provided that one terminal of the bell of the instrument can be connected to it instead of to the receiver of the telephone and to the line wire. Fig. 4 is indexed in exactly the same way as is Fig. 2, and hence no further explanation of the index letters is needed. In this case there is no necessity for a two-way plug switch, as per Fig. 3, or any equivalent appliance, since the introduction of the third wire removes

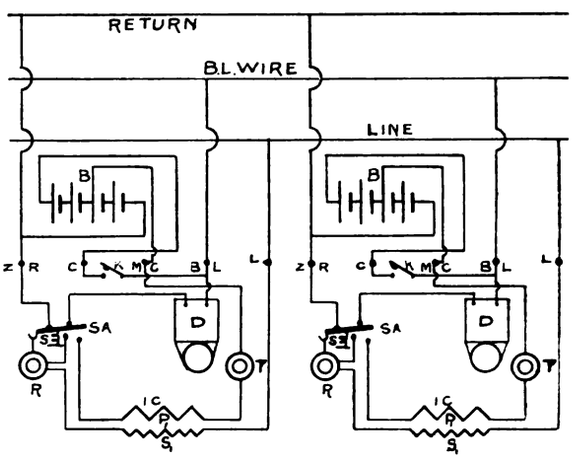

FIG. 4.

the cause of such a necessity. An alteration will, however, have to be made in the internal connections of every instrument. In the two-wire system, the right-hand terminal of the bell (see Fig. 2) is connected to the line-wire receiver and to the end carbon of the battery, whilst the left-hand terminal of the bell is connected to the upper terminal stud of the switch arm, S A. Now, in the three-wire system the first two connections—*i.e.*, the line and receiver connections—are disposed of, while the other two remain as in the former case. In disposing of these two connections another terminal, marked B L, could be well provided, as in the diagram. Then to this terminal the third wire is connected, as shown in Fig. 4.

The *modus operandi* of this system is as follows: When it is required to bring any one instrument into communication with another, the key, K, of the former is depressed, with the consequence that *all* the bells are set in action, and, following the arranged code of signalling, as referred to in the discussion of the previous system, or any other suitable and prearranged code, a certain signal is given to all the instruments. The instrument which answers to the signal given is connected to the communicating instrument by taking the receiver off the switch arm, S A, whilst the remaining six instruments should not—because they need not—be touched at all. When the communication is at an end the receivers are replaced on the hooks, and then the whole system is again normal and ready for the intercommunication between any two telephones. As is readily seen, this system is a great improvement upon the previous one, and the writer would strongly advise the querist to instal this system in preference to *any* two-wire system, even although the number of lines which are used is greater.

Digitized by Google

*The Four-Line Wire System.*—This system has been included in our considerations because, whilst not possessing any distinct advantages or qualities over the three-wire system, yet, nevertheless, it is a system which is even more flexible than the three-wire system, though the results obtained will be precisely the same in the two cases. In this case the bells are connected across two line wires, which are separate from the line wires used for the transmission of messages. In Fig. 5 all the necessary connections for two of the eight instruments are shown, the remaining six instruments being connected up in precisely the same manner as the two in the figure.

The *modus operandi* of this system is exactly like that of the three-wire system, and hence there is no need here to explain it, as reference to the latter will show how to work and use the instruments if this system be adopted. It cannot be said, however, that this system is worth adopting, because a fourth wire is run with no resulting increase in the efficiency and general usefulness of the system. The writer has been wondering whether or not an earth-return system could not be devised, and it has occurred to him that, in connection with the three-line wire system, the extra wire could conveniently be dispensed with, and, in place of such, the water in the canal could serve as a conducting medium, especially if there is any trace of metallic matter or salts in the water. In such a case the right-hand terminal of each bell should be connected to a

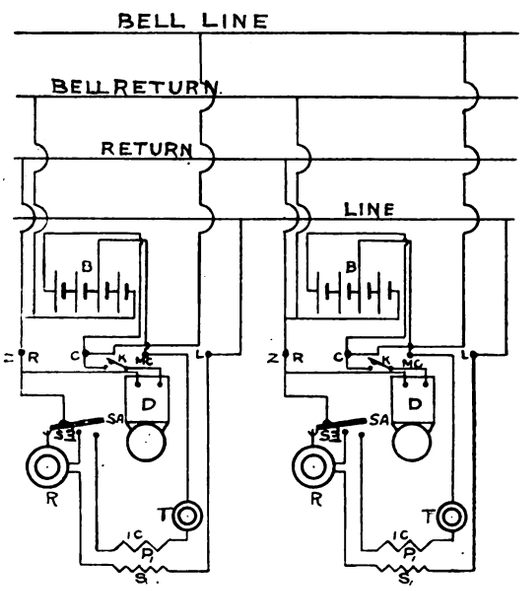

FIG. 5.

wire, which should be slightly weighted, and at the end of which there should be attached a plate or equivalent conductor which would provide a sufficiently large conductor area. Unless this is carried out, the possibility is that, at times depending upon conditions, the bells will refuse to ring, and will not even be coaxed to ring. The wires are then placed in the water at points which are immediately opposite the huts. All other connections remain as in the three-wire system. This method of arranging the third conductor would render this system still more serviceable from the standpoint of the number of wires, it would facilitate erection, and there appears to be no reason why its working qualities should not be, at least, equal to those of the three-wire system.—B. W. G.

*Answer to No.* 768 (*awarded* 5*s.*).—Either of the two usual methods of signalling—viz., battery and magneto—are available for this arrangement, but as there is a considerable length of open wire placed in an exposed position, a magneto system should be chosen in preference, although the cost of instruments is higher than with a battery system. It is less likely to get out of order, the maintenance is less, whilst the strength of the signals is constant, thus ensuring proper discrimination of calls. Two wires should be run throughout, and will be found sufficient. Every precaution should be taken to keep good insulation by the use of standard insulators and indiarubber-covered leads, a pair of which should be shunted from the two lines into each station.

The simple method of bridging each instrument across the line may be dismissed, for, although workable, the signals would be confusing, as the eighth station would require eight signals, and great distraction at the other stations would occur. If, however, the instruments are adapted as shown in Figs 1 and 2, only four rings need pass, which is within reasonable limits. Each instrument should be provided with generator, with automatic cut-out, switch hook, and two simple Morse keys, in addition to the speaking circuit (which should contain induction coil). It will be necessary to specify when ordering the instruments that the wiring should correspond with the sketch. This should cost very little, as the constructional parts are not affected. To describe the arrangement, it is seen that all the bells are permanently shunted from the line to earth, four bells being connected to the A line and the other four to the B line. They should be branched alternately as shown to ensure an even distribution of the bell earths, and conse-

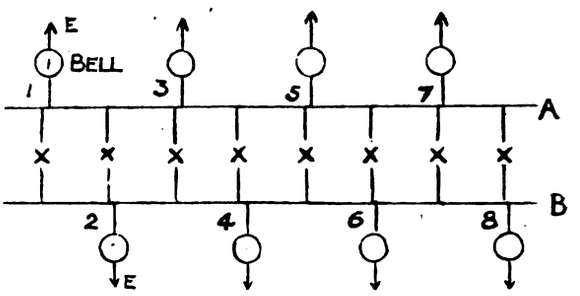

FIG. 1.

quently a quiet line free from inductive noises. When the line is not in use, only the earthed bell of each instrument is on the line, as the switch hook disconnects the other parts of the instruments. When a station desires to call another, No. 3 for instance, he will depress Morse key M, and thus by putting earth on the B line and on his generator he is able to send an earthed ringing current along the A line; only four bells will be actuated, and signals up to four will determine the station wanted. Similarly, stations on the B line are called by operating Morse key $M_1$ during the act of ringing. The cut-out of the generator is a cam action which removes spindle, S, from spring, D, allowing the latter to meet contact, C, during the act of turning. As seen

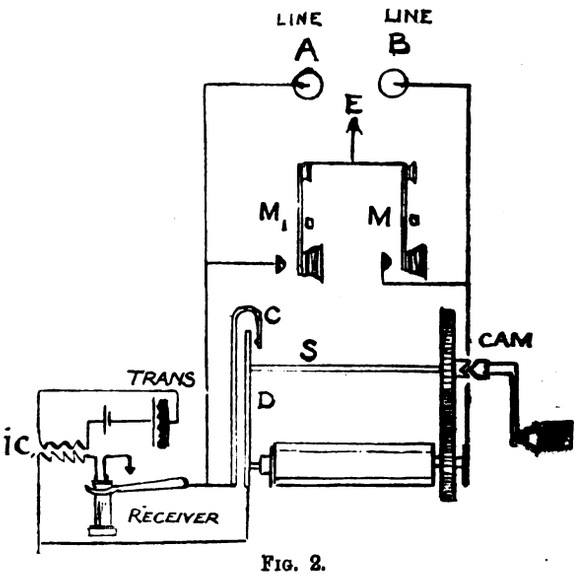

FIG. 2.

in Fig. 2 the contact of spindle, S, and spring, D, normally short-circuits the generator and provides a direct path for the secondary circuit. This short-circuit is removed whilst ringing and current passes through contact, C, direct to line or earth according to the key depressed. It is essential that all earths should be good and free from unsoldered joints. All bells should have a resistance of 1,000 ohms each, whilst if it is necessary to introduce exterior bells or indicators, they should be preferably placed in series with the instrument bell.—F. R.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

776. A four-core telephone cable 4½ miles long connects a sub-station to a generating station. The cores are twisted in pairs and used as two separate telephone lines. It is required to put up a pair of single-stroke bells, one at either end, to be worked by means of Morse keys in order to signal from generating station to sub-station, and *vice versâ*. Can this be done with existing cable, without interfering with the proper working of the telephones? If so, how? If not, why not? The resistance of the line (lead and return) is 350 ohms.—J.

### ANSWERS.

*Question No.* 769.—In a variable-speed motor the speed variation, say from 1 to 3½, is effected by varying shunt excitation by resistance in circuit. Auxiliary coils are placed between shunt coils and are in series with armature. In other respects the machine is connected as a long shunt motor. The machine is sparkless from no load to full load at all speeds, and at all speeds on reversal, with fixed brushes, the output remaining constant. Explain theory of sparkless commutation and influence of auxiliary poles on same. At certain low excitations, if the brushes were shifted 1mm. in the backward direction the motor ran away (hunted), and got up an abnormal speed in a second's notice. Explain this peculiarity.

*Answer to No.* 769 (*awarded* 10*s.*).—In tackling a question like this it is best to first consider what happens at the time of commutation in a machine, then give the theory of sparkless commutation, afterwards considering the case in point. When any one commutator segment is coming up to a brush, it is carrying a current through the coil to which it is attached of a certain magnitude and certain direction. After passing under the brush there will be an equal current now flowing, but in the opposite direction, and whilst under the brush the coil is short-circuited through the brush. Owing to the self-induction of the coil, this current will not die down and then grow again in the opposite direction instantaneously. Hence it is necessary that whilst short-circuited a current shall be generated in it of a similar magnitude and direction as that which will be passing through it after leaving the brush. This is accomplished by having the coil in a field of such a strength and direction so as just to accomplish this. If this is not done, there will be a tendency to sparking. The time necessary for the current to die down and then grow again in the opposite direction may be calculated from the following formula:

$$C = \frac{E}{R}\left(1 - \epsilon^{-\frac{Rt}{L}}\right)$$

In this

C = current in amperes;
E = reversing E.M.F. in volts generated by the coil in the weak reversing field;
R = resistance of coil and brush contact in ohms;
$\epsilon$ = 2·71828 = base of Napierian logarithms;
$t$ = time in seconds;
L = coefficient of self-induction in henries.

If this equation be solved for the value of $t$, we get

$$t = \frac{L}{R}\left(\frac{\log \frac{E}{E - CR}}{\log \epsilon}\right).$$

This gives the time the current takes to grow to the required value, so double this time should give the required time for it to die down and then grow up again. At first sight it may appear that the value E − C R in the denominator of the fraction in the numerator is equal to nothing, but this is not the case here, as if E be sufficiently large, and the time be prolonged, this short-circuit current will grow to a larger value than is required. The above is one theory, that the coil when commutated must be in a sufficiently strong reversing field for a sufficiently strong current to grow in it to the magnitude of that which will be passing through it after it leaves the brush.

Mr. Hobart in his paper read before the Institution at the Glasgow Engineering Congress in 1901, however, says that he doesn't think this idea of a reversing field has so much to do with sparkless commutation as reactance voltage, and goes on to say that he can design a machine to commutate sparklessly in a field of the wrong polarity. The value of this reactance voltage is given by the formula

$$r = 2\pi n L C,$$

where $r$ = reactance voltage in volts;
$n$ = periodicity of the reversal;
L = the coefficient of self-induction in henries;
C = the current in amperes.

The value of $n$ is given by $\frac{P}{2T}$, where P = the peripheral speed of the commutator in inches per second, and T = thickness of brush in inches. The value of $r$ should not exceed 2 or 3 for a well-designed machine. He considers a suitable value per ampere-turn per centimetre length of embedded portion of each turn to be 4 C.G.S. lines, and ·8 C.G.S. lines per ampere-turn per centimetre length of the free portion of the turn to calculate the value of L.

The currents circulating round the windings of the armature create a field which is at right angles to that due to the field poles. This is shown in Fig. 1, where it will

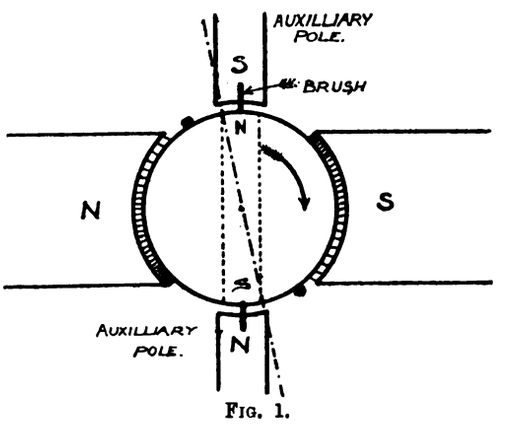

FIG. 1.

be seen that in this particular case I have indicated the flux due to the armature ampere-turn makes a north pole at the top and a south pole at the bottom. This flux is superposed on that due to the field coils, and distorts it in the manner shown, weakening the trailing tips and strengthening the leading tips of the poles in the case of a motor. Now, the necessary reversing field is got from the trailing tip of the pole which a coil is leaving in a motor, and this being weakened by the armature reaction, it becomes necessary to rock the brushes back a little so as to get the coils in a strong enough field to ensure sparkless commutation. I have indicated the direction of the currents in the two halves of the armature by means of the two small circles on the periphery, that with the dot in the centre indicating that the current is coming towards the observer, and that

Digitized by Google

with the cross shows the current to be going from the observer. Now, assuming that the brushes in a motor have been shifted back until the plane of commutation lies along the chain dotted line, then considering the turns lying between the two parallel dotted lines, we see that in the top one the current is flowing from us, and in the bottom ones to us. Hence we have so many ampere-turns generating a flux which is directly opposing the field flux, which will have a demagnetising action. In order to counteract or neutralise this armature reaction and consequent necessity for shifting the brushes, etc., many methods have been devised, including special armature windings, as the Sayers winding (strictly speaking, this is not to overcome armature reaction, but to improve commutation by means of generating a reversing E M F. in special armature windings), different shapings of the pole-shoes to prevent the distortion of the field by putting greater reluctance in the pole-tips, the use of a continuous magnetic iron ring round all the poles as used in Bruce Peebles machines so as to obtain a field for commutating in, special windings between and in the poles, the use of slots up the poles parallel to the shaft so as to prevent the flux from shifting, and also, as in this case, by the use of special poles left unwound or wound with series turns, to neutralise and take off the flux due to the armature ampere-turns. It is obvious that as the motor is to be reversible, any compensating device must be put midway between the poles; hence the auxiliary series-wound poles must be in this position. They will be connected up so as to be of opposite polarity to those created by the armature ampere-turns, that they may have the effect of sucking up this flux and preventing it distorting the flux in the ordinary field. As both the flux due to the armature ampere-turns and that due to the auxiliary poles will be proportional to the load, because these poles will be nowhere near the saturation point, the amount of this sucking-up effect will be proportional to the load, and hence the armature flux will not affect the field flux. Hence, as this is not distorted, it is no longer necessary to shift the brushes backwards, but if they are kept in the neutral position they will be in a sufficiently strong reversing field. The use of carbon brushes is also a factor to be considered in the prevention of sparking. These, I believe, have a contact resistance about 10 times as high as copper. By means of this there is a sort of grading effect, which is useful in the following manner. When a segment is just about to leave a brush the cross-sectional area is considerably reduced, and hence the contact resistance with that segment increased. This has the effect of decreasing the current through that segment, the balance passing through the next contact which has the full area, even though the coil itself be short-circuited. This action is very beneficial. Somewhat akin to this is the method by which resistance strips are used connecting the segments to the windings, but this method seems to be going out of favour. The use of equalising connections in the winding may also help the commutation, as it prevents currents circulating from one part of the winding to another through the brushes. So much for the theory of sparkless commutation and methods of promoting it. We will now turn to the part of the question where the motor races.

I beg to question this happening with only 1mm. movement of the brushes, as that is practically nothing. The motor is running with very weakly excited fields, but there will be no cross magnetising, as the auxiliary poles prevent that. When the brushes are moved backward we get a demagnetising belt of turns on the armature as explained before, depending on the angle through which they have been moved. As the armature amperes will be great, owing to the weak excitation, the demagnetising ampere-turns will likewise be great, and this, together with the weak field, which will be more susceptible to changes now, makes an appreciable diminution in the field flux. At a time like this the field due to the auxiliary poles will be at a maximum owing to the large series current and also the large value of the armature cross-magnetising turns, which have a magnetising effect on them. Being, however, approximately 90deg. out of position, they will have little or no effect except to make the machine spark frightfully as we are commutating in this relatively strong field. The net result, then, is that the machine races, being in a very weak field, and sparks dreadfully as described.—R. A. ALEXANDER.

*Answer to No.* 769 (*awarded* 7*s.* 6*d.*).—In order to understand this question we will first consider what conditions must be satisfied for a dynamo to operate sparklessly. In Fig. 1 the coil *a* has half the total current from the brush flowing in it; when it has moved to position *b*

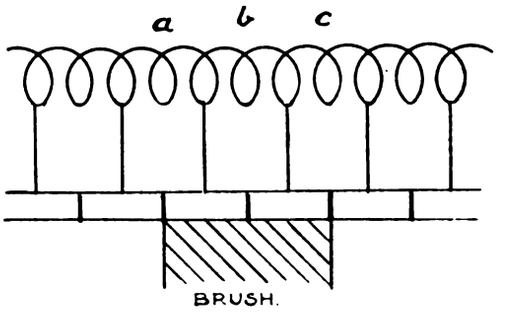

FIG. 1.

it is short-circuited, and when in position *c* the current must be reversed in direction through the coil. In order that the bar may leave the brush without a spark, it is evident the current must be reversed in the coil before the bar leaves the brush, therefore a reversing field must be provided. If the dynamo is acting as a motor, since the induced tension opposes the current, it will be seen that

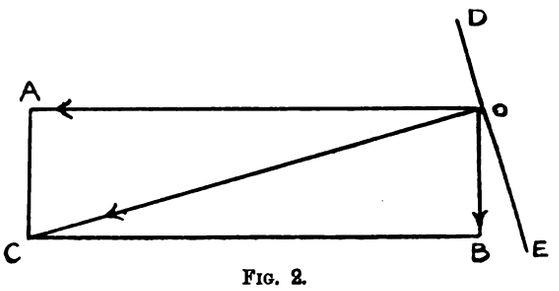

FIG. 2.

the brushes must be shifted from the neutral position in the opposite direction to that which the machine is running. We have so far assumed that there is no armature reaction, but as soon as any load is put on the motor the armature current will tend to distort the field. If O A (Fig. 2) represents the magnetic flux due to the field magnets in magnitude and direction, and O B that due to the armature

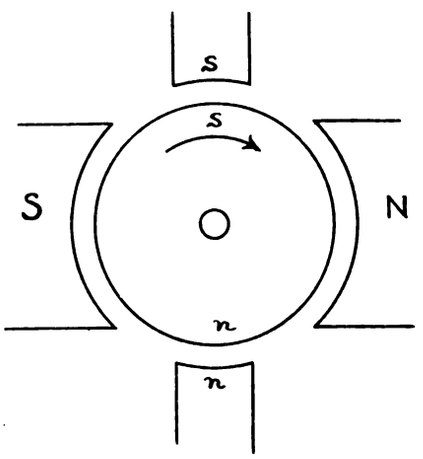

FIG. 3.

windings, the resultant flux will be represented by O C, and the brushes must be set at right angles to this—*i.e.*, on the line D E. Therefore the armature reaction necessitates shifting the brushes still further back. Coming now to the special case mentioned in the question, it is evident that as the motor runs in either direction the brushes must be set midway between the poles: and also they must be of carbon. As the brushes are not to be shifted with change

Digitized by Google

of load, it is necessary to provide some other means for the reversing field, and this is accomplished by means of the auxiliary poles.

In Fig. 3, if the machine runs in the direction of the arrow, then the top pole must be a S pole and the bottom one a N pole, in order to neutralise the poles set up in the armature by the armature current. As these poles must reverse when the direction of rotation is reversed, and must also be proportional to the armature current, it is evident that the latter must excite them—*i.e.*, they must be in series with the armature. These auxiliary poles would not be sufficient to entirely stop sparking were it not for the fact that carbon brushes are used, and it is well known that these are of considerably higher resistance than copper, and therefore, as a commutator bar is leaving the brush, the increased resistance tends to stop the current flowing, and hence the bar leaves the brush without a spark.

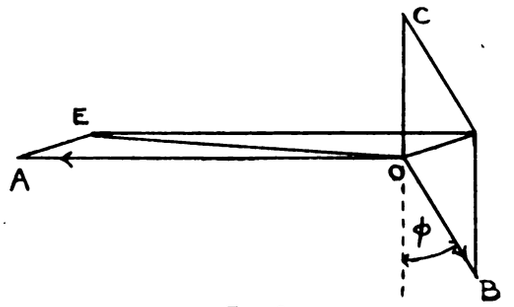

FIG. 4.

We now see how it is possible for the motor to run sparklessly at all loads and in either direction. We can also see why the motor runs away if the brushes are shifted backwards. If we draw the vector diagram of the various fluxes, we should have Fig. 4, where O A represents the flux due to the field magnets, O B that due to the armature, which is at an angle of $(90+\phi)$ with O A, where $\phi$ = angle of brush displacement, and O C the flux due to the auxiliary pole. The resultant of the system is O E, and it is seen that the field is weakened, besides being distorted. As the speed of a motor varies inversely as the strength of the field (neglecting armature resistance), it is seen that the shifting of the brushes may cause the motor to attain a high rate of speed. If the motor was loaded at the time it might pull up, in which case the fuse would, of course, blow, the current being equal to the line pressure divided by the resistance of the armature and leads.—H. C. H.

*Answer to No.* 769 (*awarded* 7*s.* 6*d*).—The motor is presumably of a similar type to that illustrated in Fig. 1.

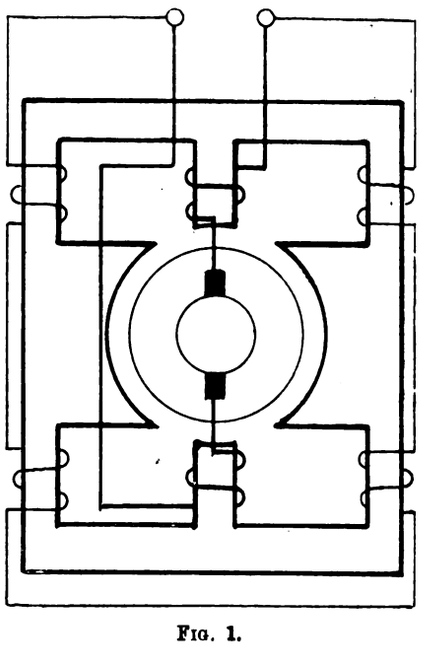

FIG. 1.

These small auxiliary poles were introduced some years ago to prevent the distortion of the field caused by armature reaction. When a motor has its speed regulated by means of varying the magnetic flux through the magnets, armature reaction becomes particularly troublesome; the province of these auxiliary poles is, therefore, to ensure that the sections of the armature winding undergoing commutation are in a pratically neutral field. When a motor—as the one under discussion—has to run in either direction the brushes must be in a fixed position, that position being such that they have neither backward nor forward lead. With a motor of this type it becomes imperative that the armature reaction is reduced to a minimum. In the case of a motor that only has to run in one direction. The brushes may have a backward lead and the result be

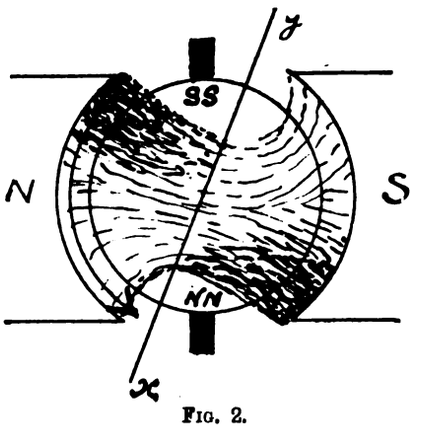

FIG. 2.

satisfactory. To attempt to reverse such a machine, however, would be totally impracticable owing to violent sparking. Figs. 2 and 3 will give a general idea of the theory of auxiliary poles in the neutralisation of armature reaction. In Fig 2 we have the ordinary case, no auxiliary poles; owing to armature reaction the "lines" pass through the armature core in some such manner as shown, the neutral axis being deflected to $x\,y$

In order to obtain sparkless commutation the brushes would require a backward lead, the distance being approximately given by $x\,y$. With a motor that ran in either direction such alteration to the brush position would be impracticable—we should then have more or less violent sparking. In Fig 3 the small auxiliary poles neutralise the magnetic effect due to the armature, and allow the magnetic flux to pass through the armature core as shown. The neutral axis is not deflected, but passes through the brushes, which are in the best position for commutation. As the winding round the auxiliary poles is in series with the armature, the auxiliary poles become stronger as the armature reaction increases. Any extra amount of armature reaction is, therefore, met by a correspondingly greater

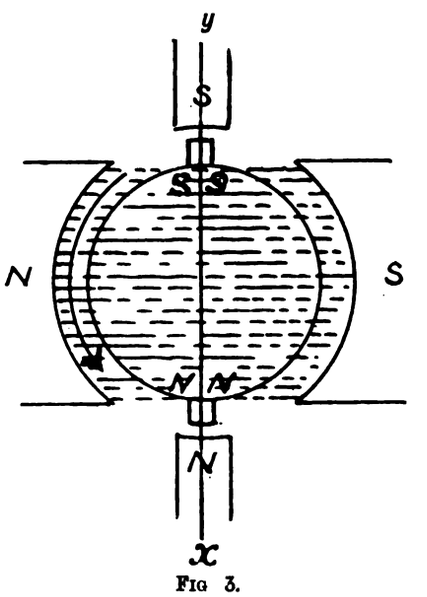

FIG 3.

neutralising effect on the part of the auxiliary poles. The neutral axis is then kept in its normal position, as shown

Digitized by Google

in Fig. 3. Auxiliary poles are now a thing of the past, most designers using other methods of construction.

To explain the running backwards when brushes are displaced, the field being weakly excited, consider Fig. 4. The brushes being shifted, so also is the polarity of the armature. Although the movement may be but through a small angle, the auxiliary poles tend to still further deflect the armature's polarity; this is shown diagrammatically by the positions of the letters representing armature poles. The armature is then

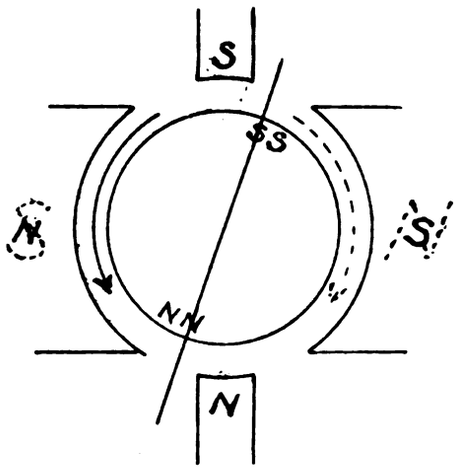

FIG. 4.

enabled to reverse the polarity of the magnets; original polarity is marked in black, reversed polarity in dotted letters. The armature will then run in the opposite direction, shown in the figure by a dotted arrow.—M. M.

*Answer to No.* 769 (*awarded* 5*s.*).—As is now well understood, there are two methods of obtaining sparkless commutation in an ordinary motor—first, keeping the reactance voltage low and depending on brush reversal, and second, using a reversing field by giving a lead to the brushes. In practice a combination of the two methods is generally used, but in the case of a motor with large speed variation neither method is easily applicable, for it is necessary to wind the motor with a large number of turns to get the low speed, with the result that it is almost impossible to get a low reactance voltage at the high speed, while at the high speed it is no use to rock the brushes, as the

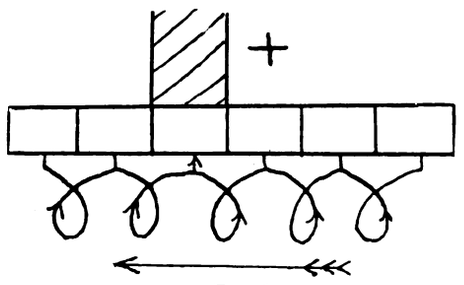

FIG. 1.

armature field completely overpowers the weakened main field and reverses the polarity of the trailing tip. Consequently it is necessary to provide some independent means of reversal.

Considering Fig. 1, it may be seen that the current in all coils to the right of the brush flows in a counter-clockwise direction, and in all coils to the left of it in the clockwise direction. Therefore the current in each coil has to be reversed while it is short-circuited. Now, each coil, being in a slot, is surrounded by a large number of lines of force which reverse with the current, and in reversing cause an E.M.F. in the bar, which always tends to prevent any alteration of the current in intensity or direction. This E.M.F. is called reactance voltage, and to overcome it it is necessary to inject into the coil an equal and opposite E.M.F., and this is the purpose of the auxiliary pole. Note that in a motor the E.M.F. caused by the rotation of the armature is in opposition to the current, therefore the auxiliary pole must have the same polarity as the main pole which the coils have just left.

The reactance voltage may easily be calculated from Hobart's formula, which has many times appeared in these columns, but stated more briefly it is equal to $\frac{d\,N}{d\,t}$, or the rate of change of lines surrounding the conductor. The E.M.F. caused by the motion of the coil under the auxiliary pole may also be expressed by $\frac{d\,N}{d\,t}$, and the two values must be equal and opposite.

Another way of looking at this, and perhaps a more convenient way, is arrived at by integrating $\frac{d\,N}{d\,t}$ over the whole time of short-circuit, which gives us N—that is, the total change of lines around the conductor in the slot must be equal to the total number of lines cut during short-circuit in passing under the reversing pole. The number of lines surrounding a conductor in a slot is given by Parshall as 10 per ampere-turn per inch of slot, and as these change from positive to negative, the total change is 20 per ampere-turn per inch, and this gives the number of lines to be cut under the reversing pole. In calculating the winding on the auxiliary pole, it must be remembered that it is necessary first of all to put on sufficient ampere-turns to balance the ampere-turns of the armature, and then add sufficient to drive the required flux through the auxiliary circuit.

Reversing poles are by no means new. They were mentioned as far back as 1885 by Mather in *La Lumière Electrique*, and Swinburne took out a patent for one of a simple type in 1889. L. B. Atkinson patented a number of similar devices in the early nineties; but although various makers have played with them at different times, they seem to be only now coming into serious use for variable-speed motors and high-speed turbo-driven generators.

With regard to the second part of the question, it will be seen from Fig. 2 that if the brushes are given a backward lead the motor becomes a differentially compounded

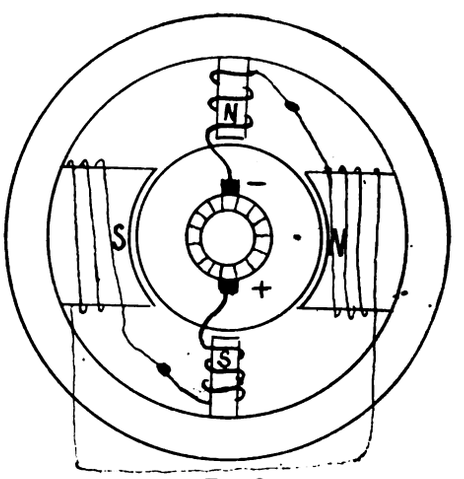

FIG. 2.

one, the series winding giving a field in one direction and the shunt in the other. If the shunt is sufficiently weakened, the total field will be reversed; but if this point is not quite reached the aggregate field will be very weak, and excessive speed will be the result. W.

ELECTRICAL PRINTING.—Messrs. J. H. Holmes and Co. have reissued, under date March, 1905, a revised list of newspapers, printers, and paper mills where their machinery is employed. The regular growth in the size of this issue shows how general the use of electric motors for driving printing machines has become. In glancing through the list one also notices what a large horse-power is needed by some of the printing works electrified. Thus, a rapid glance shows that installations between 100 h.p. and 500 h.p. are quite common. The number of motors employed in these larger installations is also an evidence of the advantage which has been proved of having individual motors to drive each printing machine.

Supplement to "The Electrical Engineer,"
APRIL 21, 1905.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

777. What is the customary limit of density of current (per square inch sectional area) in feeder cables? In what degree is the limit affected by the proximity of other feeders, or by the nature of the coverings, both protective and insulating? The reason for asking this question lies in the observation that a feeder (carrying 1,000 *a* per square inch during a breakdown of another feeder) became heated to such an extent as to alarm the workmen and jointers who were repairing the defective cables and had exposed the sound feeder. The feeders are lead and paper covered copper cables laid in tarred sand in wooden boxes.—E. B.

### ANSWERS.

*Question No.* 770.—In installing boiler feed pumps in generating stations the present-day practice seems to be either a direct-acting steam pump, giving a slow-speed highly efficient pump but a wasteful system of driving, or an electrically-driven three-throw high-speed pump, giving an economical method of driving but a wasteful type of pump, generally driven through two reduction gears. How is it that a combination as described under is not used—viz.: slow-speed electric motor coupled by worm gearing to a slow-speed (2-10 double strokes per minute) three-throw pump, thus giving economy of driving and economy in pumping, worm gears at present obtainable being of high efficiency and large ratio

*Best Answer to No.* 770 (*awarded* 10*s.*).—It has been demonstrated beyond doubt that electrically-driven auxiliary plant is by far the most economical. In a large station the total amount of steam necessary for the auxiliary plant (the latter being electrically driven) need not exceed 3 per cent. of the steam required for running the engines. Where steam is used to drive the feed, circulating, and air pumps, stokers, scrapers, conveyors, etc., the steam consumption of these may reach as much as 15 per cent. of that for the main engines. The minimum which steam auxiliaries use is probably from 10 to 12 per cent. of the steam consumption of the main engines. The following figures are from results obtained in actual practice on the 2,000-kw. direct-connected generators in the Union-street station at Brooklyn, all the auxiliary plant being electrically driven:

| | Percentage. |
|---|---|
| Boiler feed pumps | 0·42 |
| Air-pumps of surface-condensing plant | 0·53 |
| Circulating pumps of surface-condensing plant | 0·87 |
| Total for main auxiliaries | 1·82 |

It may be of interest to compare steam and electrically driven feed pumps. A very good example is to be found at the Pinkston generating station of the Glasgow Corporation tramways, a very complete description of this station and its equipment being given in *Traction and Transmission*, vol i., p. 253, from which the following remarks *re* feed pumps are abstracted:

*Feed Pumps.*—For supplying the boilers with water there are four electrically-driven feed pumps and one steam-driven feed pump, the former from Messrs. the Mirlees-Watson Company, and the latter from Messrs. C. and J. Weir, Limited. The electrically-driven pumps are each capable of delivering 8,000 gallons of water per hour against a boiler pressure of 180lb. per square inch. Each pump has three plungers of 6in. diameter driven by a three-throw crankshaft running at 45 revolutions per minute. The driving motor (supplied by Messrs. D. Bruce Peebles and Co.) is connected up to the 500-volt circuit, and can develop 27½ b.h.p. at 725 revolutions per minute. Double-reduction gearing is used to bring down this speed to 45 revolutions per minute, which is the speed of the pump. The steam-driven feed pump is of the twin-compound type, consisting of two separate direct-acting pumps of the well-known Weir type, connected together in such a way that either pump may be used independently; or, as in ordinary service, the steam from the cylinder of one pump exhausts into the steam-cylinder of the other. In addition to this, the steam is used expansively in the cylinders, which has the effect of slowing down the piston towards the end of the stroke, thereby avoiding the sharp return or shock which would otherwise occur. The steam-cylinders of the pump are 12½in. in diameter and 24in. stroke, while the pump cylinders are 9½in. diameter. The pump cylinders collectively can deliver 16,000 gallons of water per hour, against a boiler pressure of 180lb. per square inch, when running at their normal speed of 12 double strokes per minute.

An interesting paper read before the Queensland Institute on "High-Speed Feed Pumps and their Inefficiency" will be found in the *Electrical Engineer* for Jan. 13, 1905, p. 56, in which the author (Mr. E. C. Barton) gives a comparison between a slow and a high speed pump, pointing out that the greatest source of inefficiency of the high-speed pump lies with the friction of the packing, which is given as being 10 times greater in the high-speed pump than it is in the slow-speed pump. Incidentally, it should be noted that the loss due to inertia of the water in the delivery pipes is very much greater with a high-speed pump than with one built for a slow-speed.

Thus we see that an efficient pump must be of the slow-speed type, and in order to get a good overall efficiency the pump must be driven by an electric motor. In connection with electrically driven auxiliaries, the tendency of modern practice is to instal continuous-current motors for driving purposes, due probably to the economical method of speed regulation of this type of motor compared with induction motors. In cases where a low motor speed is required the induction motor is decidely inferior to the direct-current motor as regards efficiency and operation. In large power plants a supply of direct current is always available, and the pump motors, etc., may be run off this circuit.

A brief inspection may now be made of the effect of speed on continuous-current and induction motors, the following remarks being based on Mr. H. M. Hobart's valuable paper on "The Rated Speeds of Electric Motors as affecting the type to be employed" (*Journal* of Institute of Electrical Engineers, vol. xxxiii., p. 472). Mr. Hobart in this paper gives comparative designs for motors of 150 h.p. of the continuous-current and induction types. The principal conclusions to be drawn from these designs are briefly as follows: (1) the general performance and the mechanical construction of induction motors improve rapidly with increasing rated speed; (2) the general performance and the mechanical construction of continuous-current motors improve rapidly with decreasing speeds; (3) the use of low-speed induction motors and very high-speed continuous-current motors ought to be avoided whenever this is commercially practicable.

The curve of Fig. 1 is of interest, and is plotted from data taken from manufacturers' catalogues for continuous-current motors of 15 h.p. at various speeds. It will be observed

Digitized by Google

that for very low speeds the cost of the motor increases very rapidly. With continuous-current motors of a given output the efficiency at full load does not vary very much with the speed, while with induction motors the efficiency and power factor are very low for low speeds. This will probably explain the reason for the preference of continuous-current motors for driving pumps other than those of the centrifugal type.

It will thus be seen that for an economical pump running at, say, 10 revolutions per minute, the motor cannot be built economically unless a large reduction ratio be inserted between motor and pump. It is probably due to this that electrically-driven feed pumps run at comparatively high speeds, as there seems to be a prejudice against the use of worm gearing. The motor, from the economical standpoint, must run at a fair speed, and with spur gearing with a reduction of 1 : 20 or 1 : 30, this gives a high pump speed, resulting in a wasteful type of pump. Thus for an economical pump, and also an economical method of driving, the limiting feature is the reduction gear. In connection with reduction gears for moderate powers we have the choice of (1) ordinary spur gearing, (2) worm gearing, and also (3) spur gearing with special double helical teeth. The first of these may be dismissed, and the final comparison rests with worm gearing and double helical wheels. The

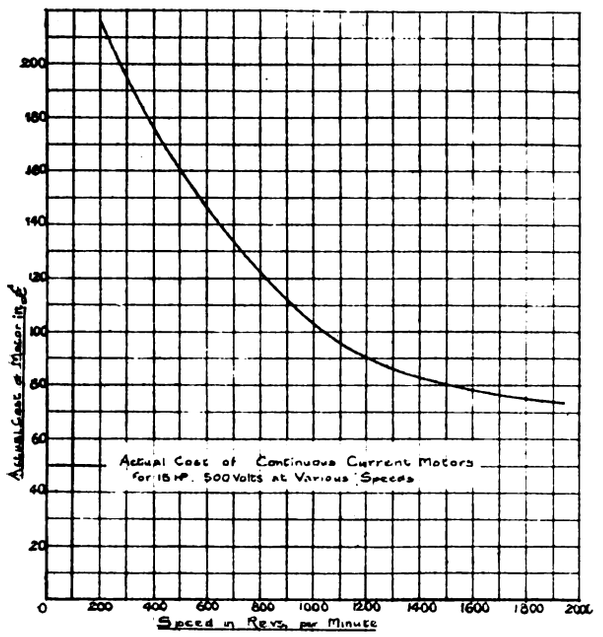

FIG. 1.

principal objections to worm gearing which appear to be apparent are (1) axis of motor at right angles to axis of pump, and (2) end thrust of worm to be taken up by ball bearings. The wear and tear of worm gearing, when properly constructed, is very small, indeed, and it must not be overlooked that to obtain a high efficiency requires a carefully-designed worm, good workmanship, and efficient ball bearings, but a very slight error in design, or the absence of a proper oil bath, may reduce the efficiency enormously. The Oerlikon Company has made extensive use of worm gearing fitted with ball bearings, the results being very excellent.

The curve shown, Fig. 2 (taken from Mr. Philip Dawson's exhaustive work on "Electric Cranes"), is a result of several tests recently made on worm gearing by the Oerlikon Company. The worm in question had five threads, with a diameter of $3\frac{3}{4}$in. at the pitch line, and a pitch of 7·28in., the wormwheel had 68 teeth, and the diameter at the pitch was $31\frac{1}{2}$in. It is to be noted that the efficiency is very high when above 10 h.p. is being transmitted. The motor connected to the worm ran at 780 revolutions per minute, and the ratio was 5 : 68.

The third class of gearing—viz., spur gearing with special machine-cut double helical teeth—has only recently been placed on the market, and it is intended as a substitute for worm gearing. The teeth of this gear are cut on a special machine, and the double arrangement is obtained by staggering the teeth on one side with respect to the other. This arrangement permits of the cutter to finish off the teeth completely, so that no further machinery is necessary. In the pinions, the space where the teeth intersect in the centre is turned down to a diameter corresponding to the diameter at the roots of the teeth. Due to the arrangement of staggering the teeth, the gear is practically noiseless since there is no backlash, and the engaging surface of the teeth is much greater than in other

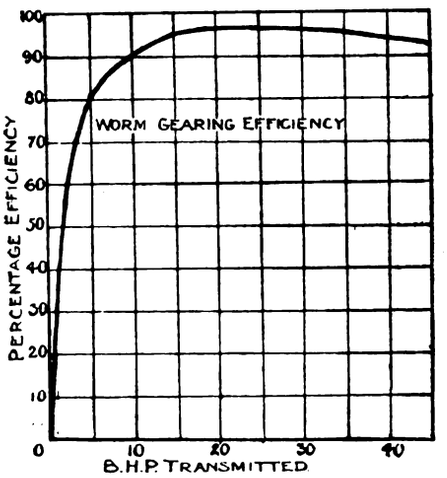

FIG. 2.

forms of spur gear. The arrangement of the double-reduction gear with these wheels is of special interest, and will be clearly understood by reference to Fig. 3, which shows a vertical section through the centre of a double-reduction gear. The shaft of the motor is fitted with a half-coupling, A, which is connected to another half-coupling on the shaft, B. A pinion, C (with double helical teeth), is securely fixed to this shaft as shown. This pinion drives a wheel, D, which is securely keyed to an extension of the boss of the pinion, E. This pinion drives another wheel, G, which is keyed to the low-speed shaft, H. The pinion, E, runs loosely on the shaft, F, which is fixed in the casing, an ample bearing surface being allowed. A striking feature in this gear is the arrangement of the main shafts. It will be noticed that the high-speed shaft runs on the low-speed shaft in the same direction, the end of the low-speed shaft being bored out and bushed to

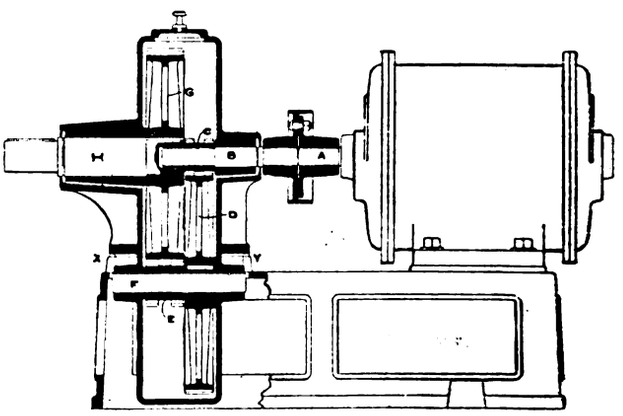

FIG. 3.

receive the high-speed shaft. The gear is enclosed in a cast-iron casing, which serves also as an oil-bath, the casing being divided along the line X Y in the smaller sizes, while in the larger sizes a second division line is added. This gear can be used for reductions up to 1 : 60, with an efficiency of not less than 90 per cent., while the reductions for 1 : 30 and 1 : 40 give an efficiency of from 93 to 95 per cent. This should prove very useful for the purpose previously mentioned, and overcomes the objection to the motor shaft being at right angles to the pump shaft, and incidentally does away with necessity for ball bearings. For a pump running at 10 revolutions per minute the 1 : 60 reduction would give a speed of 600 revolutions

Digitized by Google

per minute for the driving motor, thus enabling a favourable design to be made. We should thus have the desideratum of the station engineer.—MONOPHASE.

*Answer to No.* 770 (*awarded* 7*s.* 6*d*).—There are many generating stations where the combination mentioned by "W. T. W." is used. There has been very little published about the matter, and so not much is known about the comparative efficiencies and first costs of the different systems. Mr. H. F. Proctor, in a paper read before the British Association, gives some interesting results obtained from the electrically-operated auxiliary plant at Bristol. The figures given show a decided advantage in electrically-driven auxiliaries over steam-driven. The results are expressed in terms of steam used per brake horse-power hour on the basis of 32lb. of steam per B.T.U.

| | Steam (lb.) | Electrical (lb.) |
|---|---|---|
| Feed pumps | 98 | 43·2 |
| Donkey pumps | 544 | 95·5 |
| Circulating pumps | 90·6 | 48·26 |
| Centrifugal separators | 220 | 37·6 |

Messrs. C. D. Taite and R. S. Downe gave some time ago a very good paper on the subject before the Institution. Full particulars were given of tests carried out on the motor-driven pumps at Salford. They are slow-speed three-throw pumps, driven by slow-speed four-pole motors through worm gearing, the ratio being 1 to 12. A well-known firm

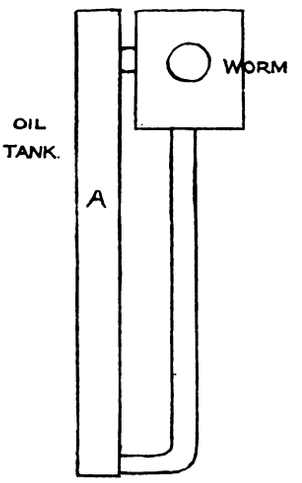

FIG. 1.

of steam-pump makers state the steam consumption of their standard 6,000-gallon pump to be as follows:

| Gallons delivered. | Pounds of steam used per hour at 160lb. pressure. | Pounds of water delivered per pound of steam used. |
|---|---|---|
| 1,000 | 130 | 77 |
| 2,000 | 253 | 79 |
| 4,000 | 490 | 81·5 |
| 6,000 | 714 | 84 |

Tests carried out at Southport on steam-pumps that had been in use three or four years gave the following average results: pounds of water delivered per pound of steam used, 49·1—which is considerably below the figures given by the manufacturers above referred to. The 4,000-gallon slow-speed motor-driven pumps at Salford gave the following results:

| Gallons delivered. | Duration of test. | Units used. |
|---|---|---|
| 1. 8,971 | 4 hours | 27·6 |
| 2. 15,822 | 4 ,, | 36 |

Assuming that each B.T.U. requires 30lb. of steam to generate it, we get the following results:

| Gallons delivered per hour. | Pounds of water delivered per pound of steam used. |
|---|---|
| 2,240 | 108 |
| 3,955 | 147 |

It will be therefore seen that the results obtained at Bristol and Salford are both in favour of the electrically-driven pump. The question of first cost, however, has to be considered, and here the steam-driven pump has the advantage. The high-speed motor-driven pump has also the advantage over the slow-speed motor-driven pump, as a slow-speed motor is much more expensive than a high-speed one of the same brake horse-power. The saving in power due to the electrical driving at Salford was found, however, to more than counterbalance the additional interest and sinking fund due to the increased first cost

The worm gear for the feed pumps at Salford was found to give trouble owing to its getting too hot for safe running. By means of the contrivance shown in Fig. 1 cool running has been obtained, and no further trouble experienced. A sheet-iron tank, A, of large cooling surface was connected by means of two pipes to the case enclosing the worm. The revolving of the worm helped the oil to circulate freely.—RESEARCH.

*Answer to No.* 770 (*awarded* 5*s.*).—The point raised in this question is one which has troubled engineers for some years, and even in these days does not appear to have reached a final and altogether satisfactory solution, as may be seen from the fact that some of the largest and most modern power-houses have been so differently equipped as regards their pumps, but for the very largest power-houses the tendency seems to be at the moment to rely upon the direct-acting steam-driven pump. This choice seems to be based upon reports of highly efficient results obtained with certain makes in this and other countries, emphasised by the fact that direct-acting steam-driven pumps to deal with 120,000 to 150,000 gallons per hour, generally speaking, ought to occupy less floor space. If one notes the size of the buildings and floor space needed for such a power-house as that at Lots-road, Chelsea, for running the Underground trains, one will observe that economy in floor space, foundations, etc., may become of greater importance than the gain of a small percentage in the working efficiency of a pump, especially when one adds to this a comparison of first-cost figures much in favour of the steam-driven pump.

This, then, leads to the point suggested in this question as to the adoption of a combined slow-speed motor and three-throw pump, seeing that highly efficient worm gearing is produced nowadays. The fact is that worm gearing has been used for pump work for several years past with very satisfactory results in those cases where the ratio has not been excessive, but in other cases the gears have proved not very durable, with a gradually decreasing efficiency as wear takes place and a somewhat high cost for renewal. Therefore, where it has been attempted to produce a plant with a high overall efficiency, possessing the element of cheapness as judged from the steam-pump standard, a comparatively high-speed motor and pump with double-reduction spur gearing has been adopted.

From this it will be seen that there is one standard from and to which one has to work and try to improve upon. That standard is the direct-acting steam-pump, whatever its required capacity may be. In a very small pump, perhaps, the poor efficiency of the steam-pump might warrant the extra heavy initial cost of a slow-speed motor and three-throw pump; but in the medium size the cost would be so much in excess, and the percentage gain not being so great, the slow-speed combination would not pay for its adoption; whilst in a pump of, say, 50 h.p, in addition to the excessive cost and floor space, one has to face the difficulty of using worm gearing satisfactorily, and the problematical gain in efficiency of the slow-speed electric over the compound steam-pump.

Thus it is seen that the question resolves itself into one solely of the most economical and satisfactory combination of efficiencies of motors and pumps, floor space, first cost, maintenance, and reliability; and although the suggested slow-speed combined arrangement might give the most efficient results so far as the consumption of power is concerned, it may not give the most economical results so far as the financial results are concerned at the end of the year.—E. A. B.

*Answer to No.* 770 (*awarded* 5*s.*).—There are many things to be considered in the answer to this question, and perhaps the chief thing we must recognise is that in commercial matters every manager is anxious to avoid making a loss, therefore he likes to adopt a method or a machine which has been proved of practical use. The actual efficiency of any machine is apt to vary with its circumstances, and

Digitized by Google

many of us know that our local conditions are insuperable, or, at all events, we prefer to endure them rather than to incur the trouble and expense of alterations which may not be sufficiently beneficial in the end. Further than this, we must bear in mind that repairs often have to be done more or less in a hurry, and the process is facilitated by the readiness with which we can buy stock things. Also manufacturers have to meet competition, hence electric motors are made as small as possible, and with as little wire as possible, because it is cheaper to build them in this way, since the speed adds greatly to the horse-power developed while it costs nothing in making the motor. As slow-speed motors are not the fashion, they have to be made to order, hence the cost is considerably enhanced. Then, again, worm gear, although efficient, is not a favourite, because it is very apt to cause a good deal of friction if the worm and the cogs do not fit exactly, and experience shows that this is often the case; then, of course, the actual efficiency of any particular machine is not equal to the possible efficiency of an ideal machine most carefully and expensively made, and running in a bath of oil for the special purpose of a record test. A three-barrel pump is in itself a very good and efficient pump if worked at proper speed and kept in proper order, and it will last almost for ever, which is a great consideration. The direct-acting steam-pumps, now fairly common for feeding boilers, are also satisfactory in all practical ways. I have used both kinds for many years, and can speak well of each.

As a practical man with long experience and sound theoretical knowledge, I cannot help thinking that there is also another reason why the suggestion of "W. T. W." should not be adopted. It is this. We know that centrifugal pumps can be fixed directly on to the spindles of high-speed electric motors, and that then they form a very efficient combination, far more so than the suggestion of "W. T. W.," and they would, moreover, be cheaper in first cost. They can be run at such high velocities that they will quite easily force water into a steam-boiler against a pressure of 100lb. or 120lb. per square inch, and they are not liable to clog as an injector is, nor would they require so much steam, and a further great consideration is that if so placed that the water was delivered to them so as to flood them, they would deal with it at any temperature with equal efficiency. The day cannot be far off when this class of pump will be found extensively used. I have answered the question somewhat shortly, but "W. T. W." will be easily able to expand it to suit his own particular views, and I hope that a little careful consideration will enable him to see the wisdom of it.—F. G. A.

*Answer to No.* 770 (*awarded* 5*s.*).—Since the maximum speed of the crankshaft for the pump mentioned in the question would only be five revolutions per minute, it follows that the motor would have to run at a very slow speed, and also the worm gearing would have a very high velocity ratio. There is nothing to prevent a pump being constructed on these lines, so far as the working and efficiency go, but since the speed of a direct-current motor in revolutions per minute is dependent on $\frac{E \times 10^8 \times 60}{N \times T \times P}$ where E is the applied E.M.F., N the magnetic induction, T the number of turns on the armature, and P the number of poles, then in order to obtain a satisfactory machine it must be a multipolar, and the slower the speed the greater the number of poles required. Now, the less number of poles a motor has for a given power the cheaper it is to construct, and the cost goes up at an alarming rate as the number increase. If, by having a slow-speed motor, gearing could be entirely dispensed with, the additional cost would be partly counterbalanced, but as in the above case a certain amount of gearing would still be required, and which would probably cost nearly as much as the form of gearing usually employed, it is clear that the first cost would be very much more; and manufacturers of machinery know perfectly well that when a machine is put on the market at a high price for the sake of a small gain in economy, business at once becomes bad. It would be interesting to compare the gain by the increased efficiency against the extra interest on capital in the case under consideration.—E. AUSTIN.

*Answer to No.* 770 (*awarded* 5*s.*).—It seems difficult to understand why engineers should continue to instal the very wasteful steam-pump for boiler feed in generating stations when they are being largely discarded on other boiler plants in favour of the electrically-driven. The only apparent reason seems to be neglect to give such a small detail proper consideration. The best type of pump for the purpose is a three-throw single-acting ram of moderate speed, and direct-coupled through two sets of *machine-cut* iron spur gearing, the motor pinion being of raw hide. With carefully designed spring-closed valves having large area but small lift, the combined efficiency—electrical to water horse-power—should be from 78 to 85 per cent., which ought to be quite satisfactory. The combination suggested would be less efficient than this, and the first cost considerably more. A good worm gear *must* be accurately machine cut and run in an oil bath with ball thrust bearings. The wheel must be of gunmetal, and the worm at least double threaded to ensure an angle of not less than 20deg. This means a costly gear, while its efficiency would then be only about 86 per cent., against 95 per cent. for two sets of machine-cut spur wheels. The slow-speed motor will cost more, and the same applies to the pump end, and the combined efficiency under test would not be more than 66 to 70 per cent.—W. F.

## REVIEWS.

**Experimental Researches on the Flow of Steam through Nozzles and Orifices.** By A. RATEAU. Translated by H. Boyd Brydon. Archibald Constable and Co. Price 4s. 6d.

This book, which is small for the price charged, makes up for its size by the large amount of original information which is crowded into its pages. The investigations on the flow of steam through nozzles and orifices carried out by the author were undertaken with a view to the design of steam-turbines. It follows, therefore, that the results he obtained by means of the careful experiments described are of great value to all who are interested in the steam-turbine at the present time. The information obtained from the study of the reciprocating steam-engine is of practically no use to the engineer when he turns to the manufacture of a steam-turbine. Again, the design of these is so largely dependent upon the velocity of steam instead of its pressure, that the problems to be solved were distinctly new. The information of a positive character on the subject under review is scattered widely through the pages of French or German scientific publications. Unfortunately, much of this information is of a theoretical character, and hence the experimental work carried out by Prof. Rateau is particularly valuable in contrast. The book commences with a brief outline on the theory of steam flow and the velocity and weight of steam which will pass through a nozzle of given shape in a given time. The next chapter deals with the many experiments carried out by the author, and these are illustrated with drawings of the apparatus actually used. The third chapter deals with a comparison of the results obtained with those which Hirn arrived at from his historical tests in 1885 on the flow of air. At the end of the book the question of the flow of hot water through nozzles is also dealt with. The tabulated results which are given throughout the volume are exceedingly valuable, and the translator is to be congratulated on having made Prof. Rateau's work accessible to all English-speaking engineers.

SCALE AND CORROSION IN BOILERS.—The British Boiler Fluid and Engineers' Stores Company, Limited, have now issued a second edition of their pamphlet on the above subject, which is written by an expert, and is of interest to all who have to deal with the upkeep of boilers. It points out the damage which may be done to a boiler by the indiscriminate use of a boiler fluid without a previous knowledge of the composition of the feed water and of the fluid used.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

### ANSWERS.

*Question No.* 771.—What is the cause of the difficulties experienced in regulating voltage on a two-phase alternating system supplied through three-core cables, and having a partly inductive load? Are these entirely absent on a four-core or double-concentric system

*Best Answer to No.* 771 (*awarded* 10*s*).—In answering this question I will first briefly describe the chief points of the two ways of connecting up the two-phase system as described in the question. In two-phase working we have two E.M.F.'s in quadrature—*i.e.*, having a phase difference of 90deg. They may be connected in two ways, as shown in Diagrams 1 and 2.

Fig. 1 shows the two phases entirely separate as they are generally worked, but it will be seen that it is quite possible to connect together the lead 2 of phase A and

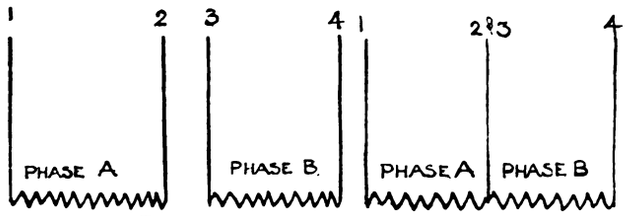

FIG. 1.

FIG. 2.

the lead 3 on phase B, thus having a common conductor for both phases, as in Fig. 2. The former is called the two-phase four-wire system, and the latter the two-phase three wire system. These are the two systems mentioned in the question. Now as the two phases have a phase difference of 90deg, they can be represented as in Fig. 3 by the vectors O A and O B, and thus we see that the difference of potential between the outer conductors is given by A B, and is equal in magnitude to $\sqrt{2}$ O A. Similarly the currents flowing in the two outers will cause a current to flow in the common conductor equal to $\sqrt{2}$ times the current in each of the outers, and I may incidentally

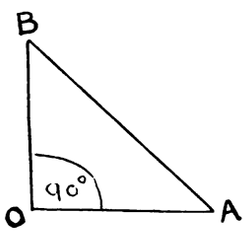

FIG. 3.

mention that we shall for this reason need a common conductor larger in section than the outers. The above condition of things is, however, when there is an inductive load on the system, only attained in theory, as the inductive load has the effect of unbalancing the voltage on the feeder, as I shall now proceed to describe. I am now assuming that both phases are loaded equally as would be the case with a motor load. I will refer to unequal loading later on in the answer.

Now as the load is inductive, it follows that we shall have a small E.M.F. of self-induction flowing in each phase. The value of this E M F. is $p$ L C, where $p = 2\pi \times$ frequency, C = the current flowing, and L is the coefficient of self-induction of the circuit. It is this E M.F. which is really the cause of the difficulties of regulation. First of all, let us consider the direction of this E M.F. of self-induction with respect to the effective E.M.F. It is well known that if we switch a current on to a circuit, the current in the circuit does not immediately attain its full value. This is due to the fact that the E M F. of self-induction *opposes* the applied E M.F. This can also be seen from the well-known law of Lenz, which states that "In all cases of electromagnetic induction, the induced currents have such a direction that their reaction tends to stop the motion which produces them."

We have now to consider the phase relation between the E.M.F. of self-induction and the effective E.M.F. Now in this circuit, if we consider one phase, the linkage of line $= L C$. If the current changes by an amount $d C$ in time $d t$, the change in linkages of lines of force is $L d C$ and the E M F. $- L \frac{d C}{d t}$. The current at any instant in the circuit is $C_m \sin p t$, where $C_m$ is the maximum value of the current. Therefore the E M F. of self-induction

$$= - L \frac{d (C_m \sin p t)}{d t}$$

$$= - p L C_m \cos p t$$

$$= - p L C_m \sin\left(p t - \frac{\pi}{2}\right).$$

Thus the E.M.F. of self-induction lags 90deg. behind the current, and since the effective E.M.F. is in phase with the

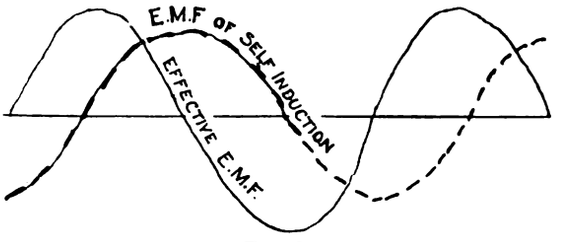

FIG. 4.

current, the E M.F. of self-induction lags 90deg. behind the effective E.M.F., as shown in Fig. 4. Thus it follows that in the two-phase three-wire system, since the effective E.M.F. in one phase is 90deg. out of phase with that in the other, and also the E.M F. of self-induction of the first

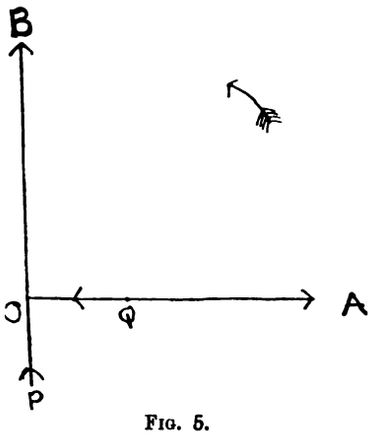

FIG. 5.

phase is 90deg. out of phase with the effective E.M.F. of that phase, the E M.F. of self-induction of one phase will be *in phase* with the effective E.M.F. of the other phase, and the E.M F. of self-induction of the second phase will be *180deg. out of phase* with the effective E.M.F. of the first phase. This very important point will be better seen by referring to Figs. 5 and 6, where I have considered these E M.F.'s vectorially. Let the vectors O A and O B represent the effective E.M.F.'s of the two phases which are 90deg. apart. Now, the E.M.F. of self-induction of phase A is 90deg. out of phase with and in opposition to O A, and is therefore represented by O P. Similarly, the E.M.F. of self-induction of phase B is 90deg. out of phase with and in opposition to O B, and is therefore represented by O Q. Thus we see that the total E M.F. acting along O B is

Digitized by Google

P O + O B = P B, and along O A it is O A − O Q = Q A. Thus we see that at the far end of the feeder we have an unbalancing of the E M.F.'s, as shown in Fig. 6. This is the real cause of the difficulties experienced in regulating the voltage as described in the question, since it will be seen that although we have equal pressures between the common conductor and outers at the generator end of the feeder, with an inductive load, through the causes shown, the voltages at the other end of the feeder will be unequal.

I think a few figures given by M. A. Oudin will give a better illustration of this phenomenon. The system was a two-phase three-wire system, like the one I have just discussed. The amperes flowing in the outers were 400, and in the common conductor 566. The voltage at the generator end of line was 100 volts between each outer and

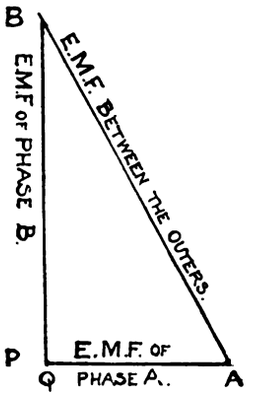

FIG. 6.

the common conductor, and 142 between the outers. Then, at the far end of the line with a frequency of 60 cycles, the voltages between (*a*) one outer and the common, (*b*) the other outer and the common, and (*c*) the two outers, were (*a*) 90, (*b*) 97, and (*c*) 134. Also, with a frequency of 125 cycles the voltages were (*a*) 87, (*b*) 99, and (*c*) 136. I think these figures clearly illustrate my argument, since it will be seen that allowing for drop in the line, on one side the voltage goes down and up on the other.

Of course, with a four-wire system there will be no such unbalancing, since the two phases are not connected together in any way whatever, and therefore the E.M.F. of self-induction in one phase can have no effect on the effective E.M.F. in the other. There may be, however, an unbalancing effect due to ordinary inequalities in the load, as is the case with the lamp load. These difficulties will, of course, be the same with a four-wire as with a three-wire system.—ERNEST P. HOLLIS.

*Answer to No.* 771 (*awarded* 7*s.* 6*d*).—The cause of the difficulties which are experienced in the regulation of the voltage on a two-phase alternating-current system working with three-core cables is one which, in itself, is due, primarily and directly, to the inductive actions upon and the inductive interactions between the cables. Also, as the conductors are situated in the three-core cables, there is a total absence of balance of these actions and interactions; in fact, speaking from a practical point of view, it may be said that there is little or no tendency, even, to provide such a state of balance, but that there is a very large mutual tendency on the part of the currents traversing the conductors of the cable to upset and derange the conditions of working. This total absence of balance leads, as a consequence, to a sequence of effects being impressed on each of the three conductors, and such effects are really the connecting links between the primal cause and the difficulties which have to be contended with in the regulation of the pressure of each of the two sides of the system, and also in the maintenance of the equality of the pressures of the two sides.

The chief subsidiary cause is, perhaps, the peculiarity of the relative positions of the three conductors one with another, the cables referred to in the above question being practically the most suitable cables it is possible to choose for a two-phase three-wire system of supply. In such a case the relative positions are out of all harmony with the principles which govern the working of the system, because the inductive action of any one conductor on either of the other two does not counteract and neutralise the inductive action of the remaining conductor on the same objective conductor. But in place of such a condition the inductive effect of the current passing along one conductor on another aggravates and augments the inductive effect of the current passing along the remaining conductor on the same one hence developing and extending, disturbing and distorting influences on the system, and not resisting and choking them. It should also be borne in mind that a very important factor, and one which should not be neglected in this connection, is the fact that all the three currents in the three conductors are "out of phase" with each other; or, in other words, that they possess phase relationships with each other. The direct result of this is not to provide the condition of balance or neutralisation of the inductive effects on each of the three conductors, even if the conductors are placed in the theoretically correct positions with relation to each other, since the two effects on any one conductor are not equal and opposite to each other, and consequently cannot neutralise each other.

Another effect which is produced in each of three separate conductors is that of the self-induction of each conductor in itself. This effect will not be very serious, or even material, compared with the mutual induction effects, owing to the peculiar condition of each conductor, inasmuch that it is a straight wire. Hence we may neglect it except in the inclusion of *all* tendencies likely to aggravate the difficulties of the regulation. Again, it is clear that if the loads on each side of the system are not equal, and the pressure at the receiving end is the same on both phases, then the currents traversing the two outers will not, as a general case, be equal, and they also will differ from the current passing along the middle wire. From this we see the self-induction effects of the conductors will vary, the extent of the variation depending wholly on the extent of the variation of the two loads and the value of the power factor of each phase.

We shall now consider this question in a graphical manner. Suppose that it is required to maintain, for *all* loads, a constant pressure of, say, E volts at the receiving ends of each of the two sides of the system, and that the angle of phase difference between the two pressures is 90deg. We can graphically represent these two pressures (as in Fig. 1) by two vectors, $E_1$ and $E_2$, situated at 90deg.

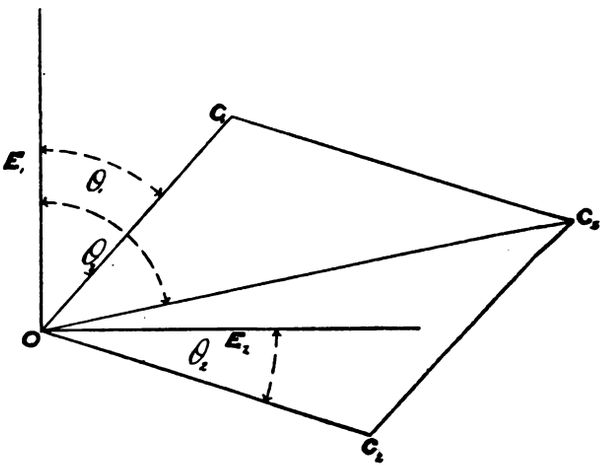

FIG. 1.

apart. Let $O_1$ be the angle of lag of the current in the first outer behind the pressure $E_1$ due to the inductiveness of the load, and $O_2$ the angle of lag of the current in the second outer behind the pressure $E_2$; also let O $C_1$ and O $C_2$ be the two currents respectively. Then, since the current in the middle wire is the resultant of O $C_1$ and O $C_2$, by completing the parallelogram, O $C_1$, $C_3$, $C_2$, and drawing the diagonal, O $C_3$, we obtain O $C_3$ as the middle-wire current, with $O_3$ its angle of lag referred to the pressure $E_1$. Now, considering the first phase, $E_1$ is the receiver pressure; O $C_1$ gives rise to the induced pressure, $e_1$, in the outer wire and $e'_1$ in the inner, these having a phase difference of 180deg, and also being unequal in magnitude; O $C_2$ induces the pressure, $e_2$, in the outer and $e'_2$ in the inner, these being equal in magnitude and having a phase angle of 180deg; O $C_3$ gives rise

Digitized by Google

to an induced pressure, $e_3$, in the outer and an induced pressure, $e'_3$, in the inner, these being unequal and differing in phase by 180deg. We can arrange the curves of these pressures on a base-line and find the resultant pressure

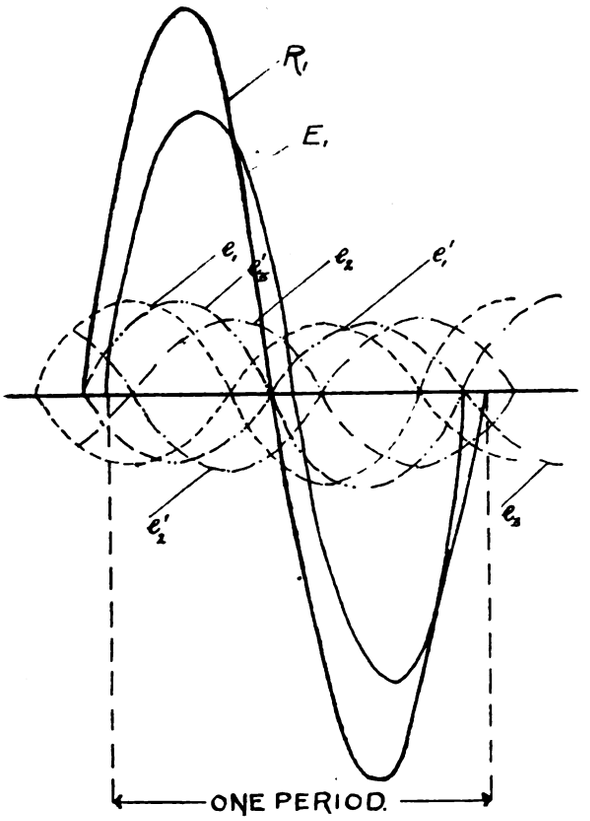

FIG. 2.

which would, for the load, be required. This resultant pressure is the generator or 'bus-bar pressure for that one phase. This process is exemplified in Fig. 2, in which, for the sake of simplicity, the pressures have been regarded as sinusoidal

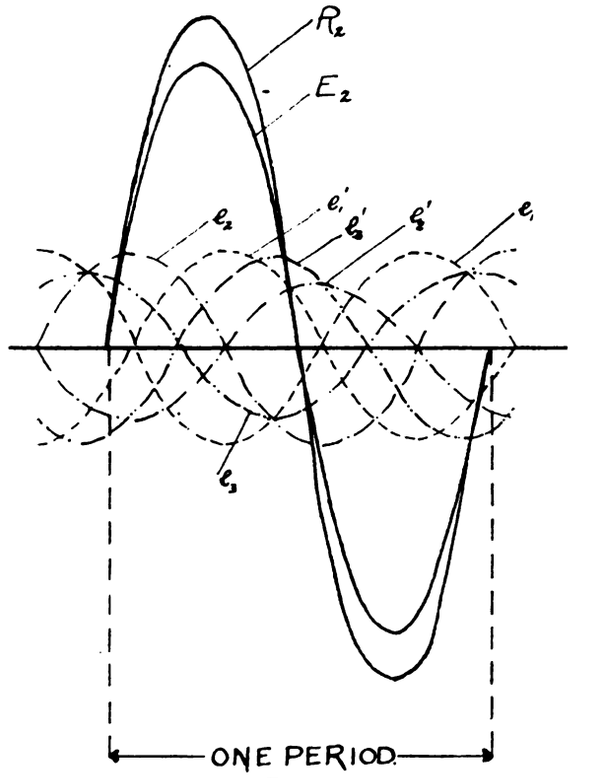

FIG. 3.

quantities; in this figure the resultant curve is marked $R_1$. This process is also used to determine the resultant for the second phase, although the induced pressures due to the actions of the various currents will not *necessarily* be the same as in the former case. In Fig. 3, $R_2$ is the resultant of the second phase. Comparison of these two curves will serve to show that they are not alike so far as general shape, maximum values, and phase displacement from the receiver pressure are concerned. If the loads are altered in magnitude or inductiveness, these curves will, clearly, be altered because the component curves will themselves be altered owing to the changed conditions. Also, the alteration of the resultant curves is not governed by any special law, hence extreme difficulty in proper regulation is the direct result.

As regards the latter part of the question, it follows from the above considerations that unless the various members of the cable are so situated that the total inductive action of *all* the members is zero, then difficulty in the regulation of the voltage of the system will be present. In the case quoted in the question, seeing that the conductors of the cable are not in such a position, inductive influences will make themselves felt in the system. But it may be said as an offset to this, that in this case the conductors are so situated that they act as condensers, and the effect of these actions is to neutralise the inductive effects. Consequently, the difficulty of regulation will not be so great as in the former case, although it cannot be said that it will be *entirely* absent. Incidentally, it may be mentioned that the ideal relative positions of the four conductors are at the corners, or ends of the diagonals, of a square, with the two conductors of one phase at the ends of *one* diagonal and those of the other phase at the ends of the other diagonal. In this arrangement the natural tendency of each conductor is to affect the other three, but, owing to the peculiar positions of the conductors, the sum total of the effects of all the conductors is almost, if not quite, zero.—B. W. G.

*Answer to No.* 771 (*awarded* 5*s.*).—The difficulty is due to the difference of the effect of the voltage drop in the common return cable on the two-phase voltages at the far end of the line. The current carried by the common return cable, $B_1$ $B_2$ (Fig. 1), is the vectorial sum of the two separate phase currents, and since the latter are displaced 90deg. or quarter period from one another, and (if the two phases are equally loaded) are equal to one another, the common return current is displaced 45deg. or one-eighth period from either of the phase currents. The voltage drop in the common return is, therefore, also at 45deg. to that in either of the other cables. The effect of these various voltage drops on the actual phase voltage measured at the far end of the line (between $A_2$ and $B_2$ or between $B_2$ and $C_2$, Fig. 1) depends not only on the value of the drops, but also on the angle of lag between the phase current and the phase voltage—*i e*, on the power factor of the external load—and for any other than a non-inductive load the effect is not the same on the two phases. This can be

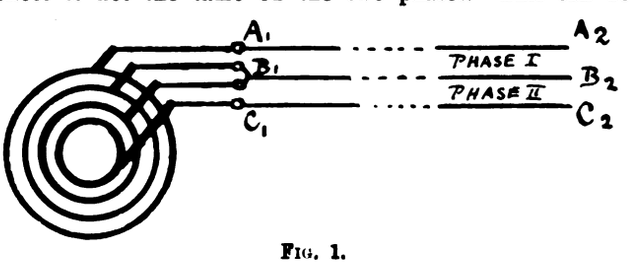

FIG. 1.

shown by two simple vector diagrams. Fig. 2 represents the case when the output at each phase of the alternator is non-inductive. In order to complicate the diagrams as little as possible, the drop in the cables has been assumed to be solely due to resistance—the presence of an additional reactance or inductive drop in the lines would only affect the results quantitatively, but not qualitatively. The lines O $A_1$ and O $C_1$ at 90deg. to one another represent the voltages of phase I. and II. measured at the generator, between $A_1$ and $B_1$ and between $B_1$ and $C_1$ (Fig. 1). As the alternator load is assumed non-inductive, the lines representing the phase currents will lie along O $A_1$ and O $C_1$ respectively. Let O A and O C be these phase currents. Then the current in the common return cable ($B_1$ $B_2$, Fig. 1) will be the resultant of O A and O C, and is shown as O B (Fig. 2). The voltage drop in the line $A_1$ $A_2$ and $C_1$ $C_2$ (Fig. 1) will be in phase with the phase currents O A and O C (Fig. 2) respectively, and may be represented by the

Digitized by Google

line $A_1$ $a$ for phase I. and $C_1$ $c$ for phase II. The drop in the common return ($B_1$ $B_2$, Fig. 1) will be in phase in with the resultant current, O B, and may be represented for the two phases by the lines $a\ b_1$ and $c\ b_2$ respectively, drawn parallel to O B. The lines $o\ b_1$ and $o\ b_2$ will then represent the phase voltages available at the far end of the line. It is clear from the symmetry of the diagram that these two voltages are equal, so that it would only be necessary to increase the exciting current of the alternator slightly at full load in order to ensure the same voltage at full load as at no load in both phases at the far end of the line.

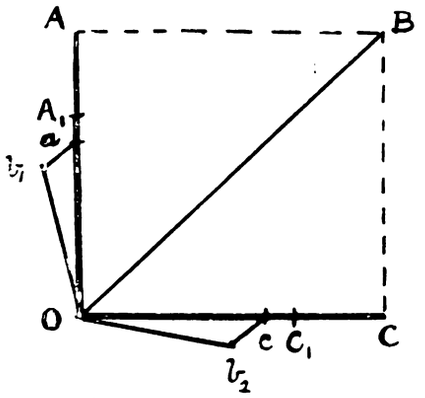

FIG. 2.

When the load becomes inductive, however, the result is very different. Fig. 3 represents this case on the assumption that the power factors and amounts of the loads are alike on the two phases. The lines O $A_1$ and O $C_1$ at 90deg. to one another will again represent the voltages of phases I. and II. normal between $A_1$ and $B_1$ and between $C_1$ and $B_1$ (Fig. 1). Let O A and O C represent the phase currents lagging considerably behind their respective terminal voltages, O $A_1$ and O $C_1$. The current in the common return will now be represented by O B, which is, of course, still at 45deg. to the currents O A and O C, but is at very unequal angles to the voltage lines O $A_1$ and O $C_1$. The voltage drop in lines $A_1$ $A_2$ and $C_1$ $C_2$ (Fig. 1) will be represented by the lines $A_1$ $a$ and $C_1$ $c$ (Fig. 3) drawn

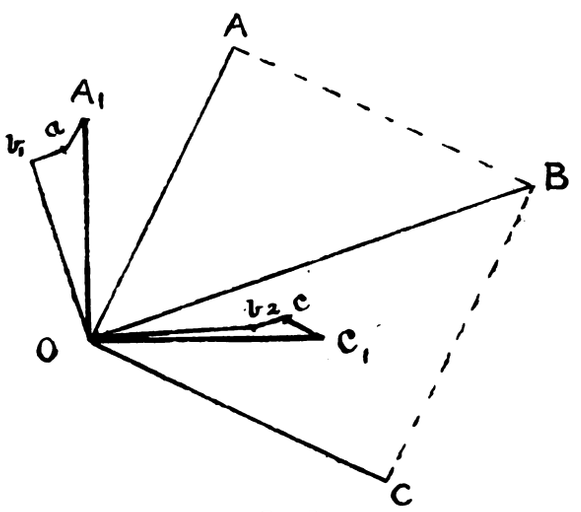

FIG. 3.

parallel to O A and O C respectively. The drop in the common return will be given by the lines $a\ b_1$ and $c\ b_2$ drawn parallel to the line O $B_1$, and the effective phase voltages at the far end of the line will again be represented by $o\ b_1$ and $o\ b_2$. It will be seen that these voltages are very unequal in this case, so that the voltages at the far end of the two phases will no longer be equal even if the phase voltages at the generator terminals are exactly alike. In such a case the voltages at the far end can only be maintained equal by separate regulation of each phase by means of feeder regulators, etc.

If, on the other hand, the two phases are kept quite separate by employing a four-core cable, the difficulty will be practically overcome, for the voltage drops in the two phases will then remain relatively alike, both in amount and in their phase relation to the terminal voltages, under all conditions of load, provided that the loads on the two phases are equal as regards amount and power factor and that the inductances of the two pairs of lines are not materially different. Fig. 4 represents this case for an inductive load. The drops in the separate return cables are here shown by $a\ b_1$ and $c\ b_2$ drawn parallel to the phase currents O A and O C, and, therefore, in line with

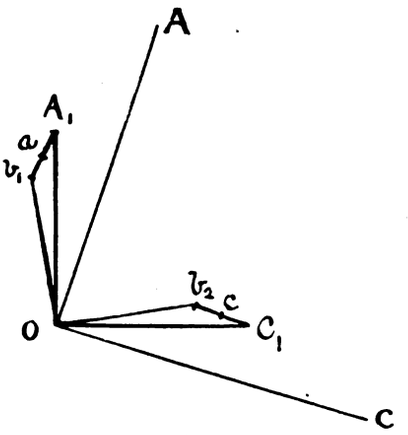

FIG. 4.

$A_1$ $a$ and $C_1$ $c$ respectively. The phase voltages $o\ b_1$ and $o\ b_2$ are equal.—Q.

*Question No.* 772.—In testing a short length of triple-concentric, lead-sheathed cable with a Silvertown set battery, volts 200, no deflections were obtained on the galvanometer unshunted, ·23deg. with 100 shunt through 50,000 ohms. On testing the same cable with an Evershed ohmmeter set, the following readings were obtained: + to −, 40 megohms; + to ⏜⏝, ∞; + to lead, ∞; − to ⏜⏝, 5 megohms; − to lead, 50 megohms; ⏜⏝ to lead 5 megohms. What is the reason for the differences?

*Answer to No.* 772 (*awarded* 5*s.*).—There is not only a discrepancy between the results of the insulation tests taken with the Silvertown testing set and the Evershed ohmmeter set respectively, but there are discrepancies in the individual readings of the latter. For instance, the insulation resistance between the negative and the neutral comes to five megohms, and that between the neutral and the lead is five megohms, and yet the insulation resistance between the negative and the lead, instead of being 10 megohms, is given as 50 megohms, therefore it is apparent that the Evershed ohmmeter readings are unsatisfactory, and hence we may conclude that the source of all the observed discrepancies is most probably here. Now the readings of this instrument will give a lower value for the insulation resistance than ought to be the case if the leads which are used to connect the instrument to the cable under test are not satisfactorily insulated from each other. Evidently in some cases this insulation was satisfactory, or the infinity readings would never have been obtained. The fact that such readings were sometimes obtained proves also that there is no leak in the testing set itself, between the terminals to which the leads are attached, sufficient to account for any error in the readings. Also between the various tests the leads have to be moved in changing their connections, and it is not to be expected, therefore, that the insulation resistance between them even if sometimes very low will always be so. The conclusion is, therefore, that leads with a poor insulation resistance were used to connect the cable under test to the Evershed testing set, and that these leads were allowed to lie on the ground, or in proximity to one another or some conductor.

If "E. H. H." will repeat the test using high-class insulation connecting leads, or taking care that the leads used do not touch anything but at their ends, he will most probably find that in every case the insulation resistance will be what is commonly called infinity, a term which really means that it is beyond the range of the testing set used.—SUPERHEAT.

[Other replies to Question No. 772 will be given in our next issue.—ED. *E. E.*]

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

778. A large institution requires a 14-h.p. motor for a laundry and also want the same motor to augment a deficient water pressure—due to high ground on which building is situated—in case of fire, by working a pump fed by the water suplpy. How can the motors be best arranged to fulfil this two-fold purpose?—A. R.

779. A three-phase induction motor, with star-connected stator windings is so arranged that each limb of the star consists of two parallel circuits, each circuit producing one set of poles and its neighbour the opposite set (see Fig. 1). If these circuits were

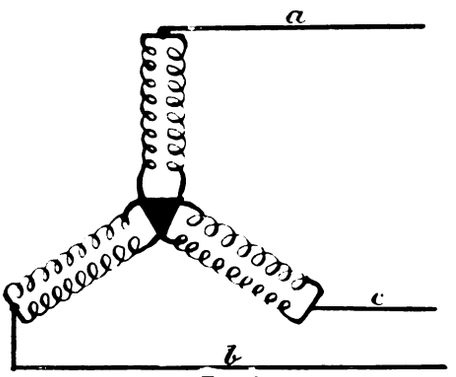

FIG 1.

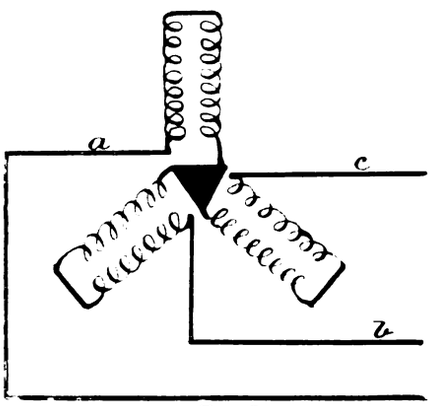

FIG. 2.

placed in series, still star connected (see Fig. 2), in what manner would the machine power factor and efficiency be affected at light and full loads —MESH.

### ANSWERS.

*Question No.* 772.—In testing a short length of triple-concentric, lead-sheathed cable with a Silvertown set battery, volts 200, no deflections were obtained on the galvanometer unshunted, ·23deg. with 100 shunt through 50,000 ohms. On testing the same cable with an Evershed ohmmeter set, the following readings were obtained: + to −, 40 megohms; + to ⌒⌣, ∞; + to lead, ∞; − to ⌒⌣, 5 megohms; − to lead, 50 megohms; ⌒⌣ to lead 5 megohms. What is the reason for the differences?

*Answer to No.* 772 (*awarded* 7*s.* 6*d.*).—An explanation is evidently required, not only of the different readings obtained from the two instruments, but also of the apparent inconsistency of the results given by the ohmmeter. In the first place, the fact that with a 200-volt battery with 100 shunt a deflection of only ·23deg. is obtained with the standard 50 000 ohms points to a defect in the Silvertown apparatus. Under the same conditions an equal deflection would be obtained with unshunted galvanometer through a resistance of 5 Ω. The resistance which would correspond to a scarcely readable deflection would, therefore, not be necessarily a very large one. It must be remembered also that resistances of this type are not constant, but depend to a certain extent upon the E.M.F., decreasing as the latter increases. The ohmmeter gives 500 volts, and the lowest resistance in this case is 5 Ω. Now, as shown above, the Silvertown set with a 5 Ω resistance would give ·23deg. deflection. That it does not when testing from − to ⌒⌣ and from ⌒⌣ to lead is probably due to the fact that the battery gives 200 volts at the most, probably a good deal less, the insulation resistance at this voltage being considerably more than 5 Ω. The battery should be examined for voltage and loose connections, and the fault will perhaps be discovered. In the rather unlikely case of its not being found here, the instrument should be examined, as the needle may be demagnetised, or the jewel dirty or damaged. The needle may be remagnetised by a few strokes from a magnet, and the jewel, if dirty, may be cleaned with a splinter of wood. Damage to the jewel or pivot is the result of carrying the instrument about without closing the lid, and so lifting the pivot off the jewel.

Of course, broken or bad connections to outside circuit would account for the failure of the Silvertown set to give a deflection, but the fact that the standard deflection is also low puts this explanation on one side. If defect lies neither in battery nor needle, it may be assumed that an internal connection has broken or become damaged, this connection being in 50,000 ohms circuit, and also in circuit with cable under test.

In the second place, as regards the apparent inconsistency of the ohmmeter readings—*e.g.*, − to ⌒⌣ 5 Ω, ⌒⌣ to lead 5 Ω, − to lead 50 Ω—it might be thought that the latter ought to be approximately the sum of the former, but when testing from − to ⌒⌣ and from ⌒⌣ to lead, the potential difference per millimetre of dielectric measured radially would be about double the potential difference per millimetre in the test from − to lead, and considering the nature of the resistances as above, the readings obtained probably represent the actual state of affairs.—D. M. H.

*Answer to No.* 772 (*awarded* 7*s.* 6*d.*).—The question does not state the conditions explicitly enough to say definitely what is the reason for the differences. Firstly, the testing pressure of the ohmmeter set may be considerably higher than that of the Silvertown set, and may produce a partial breakdown of the insulation which remained unaffected by the 200 volts, thus causing the differences. Secondly, if the "·23deg. with 100 shunt through 50,000 ohms" refers to the standardising test, the galvanometer is not nearly sensitive enough, although, of course, it should give a deflection of ·23deg. with five megohms when unshunted; but still, a tester who uses the above as a standardising test, when there can be no reason why he should not standardise it unshunted, cannot be relied on at all, and very probably used some old bell wire for connecting the ohmmeter to the cable, and sometimes happened to have them touching and sometimes not. Thirdly, assuming the decimal point is a mistake, and the deflection should be 23deg. (which would point to the great advisability of putting a cipher before a decimal fraction, as 0·23), and also that the ohmmeter set testing pressure is 200 volts, then the most probable reason is that the testing set is an alternating one, and the reading produced by capacity currents. We now assume the insulation perfect as indicated by the galvanometer, and treat the cable as a condenser. Connections:

+ to lead, the area of one plate is small and the distance apart large, so the capacity current is insufficient to affect the ohmmeter;
+ to neutral, ditto ditto;

Digitized by Google

+ to −, the area of one plate is still small, but as the distance apart is so much decreased, the capacity effect is quite noticeable;
− to lead, area increased and distance also increased, so effect about the same;
− to neutral, distance decreased, so effect increased;
Neutral to lead, area and distance about the same, so effect about the same.

This only holds true because the soft iron needle of the ohmmeter is not affected by phase difference.—J. LEWIS COOK.

*Answer to No.* 772 (*awarded* 5*s.*).—In testing the insulation of a cable whose ends are exposed to the atmosphere, or have been at some time after leaving the maker's test-room, where an even temperature was kept up during their tests, a great variation will be found, depending chiefly on the condition of the atmosphere during the various tests at various times; but assuming the cable under test by the different methods to be under the same conditions on which I base my figures, and the sets to be correct as far as comparison one with the other.

The readings obtained by the Evershed ohmmeter set are not in the least to be doubted, and the same would have been recorded on the "Silvertown set" had it been possible to obtain a higher constant than 1,150,000 (or 1·15 Ω for test convenience), and, to compare the "Silvertown set" with K = 1·15 Ω with "Evershed set" readings, the following deflections would have been obtained had it been possible to read them:

| | Evershed set. | Silvertown set with galvanometer unshunted. Battery volts 200, K = 1·15 Ω. |
|---|---|---|
| A + to − | 40 Ω | ·0287deg. |
| B + to ⌒ | ∞ | — |
| C + to lead | ∞ | — |
| D − to ⌒ | 5 Ω | ·23deg. |
| E − to lead | 50 Ω | ·023deg. |
| F ⌒ to lead | 5 Ω | ·23deg. |

As "E. H. H." does not give the value of his infinity, or to express myself better, the infinity in this case may mean anything above 50 Ω, being the highest figure given, and consequently the reading on "Silvertown set" would be less than ·023deg. I may say I have had a constant with the same type of set, though by not the same maker, with 200-volt battery = 600 Ω, and more. The reasons for the differences in readings taken by "Evershed set" are simple, and which occur with all cable tests, following the above. + to lead, which is ∞, would be A together with B and F, and + to − being 40 Ω, F = 5 Ω, B = ∞ something higher than 50 Ω, therefore + to lead would be of such value as to be unable to give a reasonable deflection on "Silvertown set," and similarly with other readings.—A. P.

*Question No.* 773.—A quantity of lighting cable (200 volts, say) is suspected of being largely composed of reclaimed rubber instead of pure. Is it possible to decide the point, naturally without referring to the makers, and what would be the effect on the cable were such found to be the case?—R. R. R.

*Answer to No.* 773 (*awarded* 7*s.* 6*d*).—In reply to the above, the decision of the point in question can be arrived at through the medium of proper and thorough tests on the suspected cables. Presuming that the cables have not been as yet laid down or used in anywise, but that they are set aside for future use, it is not a very difficult matter to conduct such tests with a certain amount of facility. In the first place, it will be well to consider briefly a few necessary points in connection with the difference which exists between pure rubber and reclaimed rubber. It is taken for granted that by reclaimed rubber is meant rubber which has been used in other cables previous to its use in the insulation of the cables in question. In all probability then, considering the trend of the modern manufacture of cables, this rubber may have been used in conjunction with sulphur and other insulating materials, as well as substances acting as mechanical protectors. In the new state, however, this rubber will have had removed from it all these foreign substances, but there will still remain traces of them in the rubber, owing to the persistence of the association of the substances with the rubber. In pure rubber, of course, no such substances are to be found, since there never exists the occasion for it to come into contact with them before it is requisitioned into use. The supreme object, therefore, of the test is to detect, as far as it is possible, any trace of these foreign substances. The first test which should be made should be an insulation test, the objective being to determine whether the insulation of the cable is as good, better, or worse than that of a cable insulated entirely with pure rubber. This can be done by taking equal lengths of the cable in question and a pure-rubber insulated cable, and testing them, in turn, by means of a Silvertown testing set or an Evershed ohmmeter set. Comparison of the two results will then clearly show which of the two cables is the better insulated. If this should be the cable in question, the tester could well conclude that his cable is a pure-rubber insulated one, but, in cases like this, it is always well to perform one or more confirmatory tests. In any case, therefore, the test should be performed with the cables immersed completely in water, and the readings of the instrument then taken. The comparison can be then made again. Also, if the tester has the time and the facility, he would do well to conduct a heat test on the rubber of the cable. An inch or two of the braiding or equivalent covering is entirely removed, and the rubber underneath this is cut away from the conductor. This rubber is then placed in a test-tube or other convenient vessel, and heat applied to it by means of a flame. The rubber is carefully watched, and the temperature is noted at which it begins to soften. If this temperature is more than 75deg. C., it may be taken for granted that the rubber is not pure; but this test is by no means conclusive, because the above temperature depends upon a large number of conditions. To test the rubber for weight will be far more conclusive than the above. If a certain volume of the rubber is taken and weighed, then the specific gravity can be readily calculated. Should this exceed 0·933, it shows that the rubber is not pure, but reclaimed. If the rubber were found to be impure, then it would in all probability lack that homogeneity which is so necessary. Also, its waterproof qualities would be in the declension. Its durability would be diminished, and the conductor, unless thoroughly tinned, would be attacked and eaten away. And, above all, the insulation would be poorer, thus producing a poor cable, whose use would probably lead to dire results.—B. W. G.

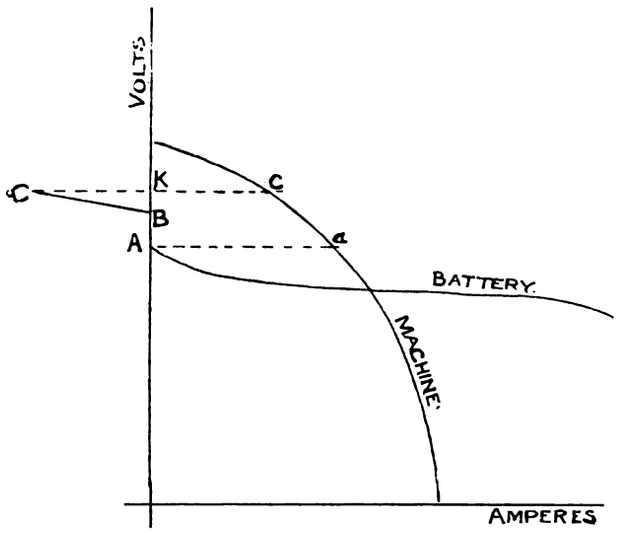
*Answer to No.* 773 (*awarded* 7*s.* 6*d.*).—There are several methods of testing the purity of rubber; perhaps the simplest and most handy test is that of burning. To take this test it is only necessary to secure a small quantity of the rubber with which the cable is insulated. If the rubber is pure, when burned it should leave a soft white ash, the dimensions being much smaller than it was before being burned; should the rubber be of a poor quality, not only will the ash be hard, but its dimensions will be practically the same. As a rule, cables are not insulated with pure rubber throughout, but have only a thin covering of pure rubber next to the copper conductor, the pure rubber being covered with vulcanised rubber. This rubber is of a different quality, and is mixed with certain compounds, of which a portion is sulphur. Should the sulphur not be thoroughly mixed the sulphur may form crystals, which dissolve out of the cable when exposed to moisture, causing small holes to appear, which will tend to weaken the insulation properties of the cable. All cables should be tested at the manufacturers according to the specification, and should stand at least a current at a pressure equal to four times the ordinary working pressure for a quarter of an hour after the cable has been immersed in water.—G. M.

*Question No.* 774.—In a description of the electrification of a railway in France some weeks ago, rotary converters were mentioned as running compounded with the series windings opposing the shunt. Explain how such machines work, and give any advantages which they possess over ordinary compound rotaries.

*Answer to No.* 774 (*awarded* 7*s.* 6*d.*).—The object of a differentially-wound converter or dynamo is to supply current automatically and alternately at voltages about two mean values as occasion requires. It is used in parallel with a battery which it charges at the higher voltage, and, in parallel with which, it supplies current to a network at the lower voltage. Its characteristic curve is represented in the figure, and from this it will be immediately seen that, running alone, it becomes demagnetised at a certain

Digitized by Google

load; this, however, is prevented by a battery, a characteristic curve of which is also represented. It is quite clear that, so long as the battery and the machine are in parallel, their voltages must be the same, from which it follows that horizontal lines cut the two curves at points representing their respective shares of the load. If the capacity of the battery is large, the horizontal part of its curve will be long, and the maximum load taken by the machine is practically represented by the point at which the curves cut. The volts supplied to the network at large loads are also roughly represented by this point. If we examine the curves we see that when the load on the battery has dropped to zero (as at A), the machine—to keep at the same voltage—must supply a certain load (*a*) Now, as soon as the demand on the network drops below this value and the volts tend to rise, the machine would



immediately begin to charge the battery but for the fact that the battery volts still rise about 15 per cent. (to B) before charging commences, and another 5 or 10 per cent. before it becomes general. When this point is reached, and the battery volts have ceased rising with the machine volts, the machine will be supplying current represented by (*c*), so that the battery curve passes through a point, C, such that C K = K *c*. Now, since the volts cannot rise beyond this in the machine (on account of the battery), the points C *c* are the last we can reach on both curves, and the machine continues to charge the battery at this rate until load again comes on the network, when the series winding and the armature drop bring the volts down below A, and the battery begins to discharge again. The points A, B, and C, of course, vary slightly according to the state of the battery.

The advantages and disadvantages of these machines over ordinary compound rotaries are obvious, each for its own particular work. This machine would, of course, be quite useless for keeping a steady voltage on, say, a traction system, apart from its battery. On the other hand, an ordinary compound-wound rotary converter would be out of the question where a battery is used, as the latter would never have a chance of discharging in parallel with the machine. A shunt-wound machine would not automatically give enough variation in voltage to charge and discharge the battery unless its characteristic curve was very steep, a result most simply and economically obtained by adding a suitable number of series turns in opposition to the shunt turns, and, in short, making a differentially-wound machine.—W. E. P.

*Answer to No.* 774 (*awarded* 7*s.* 6*d*).—This reversed series winding gives a falling pressure with an increasing load, which enables a floating battery to equalise the load on the generating plant. To anyone who is familiar with the regulation of rotary converters the above statement will make the whole question clear, and there is really no need for further explanation, but to anyone who is not versed in this matter the following should enlighten: The ratio of the alternating-current and direct-current voltages of a rotary converter is a fixed quantity, consequently one cannot be raised or lowered without the other, and is also independent of the excitation; therefore, in order to vary the pressure on the direct-current side, the applied pressure at the slip-rings must be altered. In some cases this is done by altering the transformer ratio or by induction regulators, but for automatic regulation the machine is usually provided with a series winding. At first sight it appears that this would be valueless, for it has been stated that the ratio is independent of the excitation, but with a little consideration it will be seen that this series winding can be made to vary the pressure at the slip-rings. If the excitation of any synchronous motor is varied, the driving current will also vary; and on all such machines it will be found that for a given load there is one excitation which gives a minimum input. Any increase in this excitation will cause the machine to draw a greater current, which will be a leading one, while any decrease will also cause it to draw a greater current, but in this case it will be a lagging one. In short, by varying the excitation the power factor of the machine is altered. Now, it is well known that any circuit having inductance, a leading current will cause a rise in pressure, while a lagging one will cause a fall. This inductance is generally provided by putting reactance coils between the secondaries of the trans-

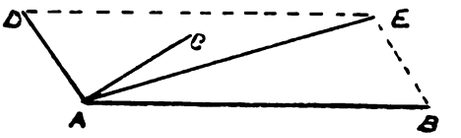


FIG. 1.

formers and the slip-rings. In order to see how the pressure is varied, a vector diagram may be employed. Let A B (Fig. 1) represent the terminal voltage of the transformers, and A C the lagging current. Then A D will be the reactance voltage at right angles to it, and A E is the vectorial sum of A B and A D which may be taken as the voltage at the slip-rings. In Fig. 2 the machine is supposed to be running with a heavier load, and the current vector, A C, is consequently made longer and is now leading on the E.M.F.; also the reactance vector, A D, is longer to represent the greater reactance voltage. By drawing A E as before we again obtain the pressure at the slip-rings, which is obviously greater than when the current was lagging. In nearly all cases the series winding is arranged so that as the load increases the magnetomotive

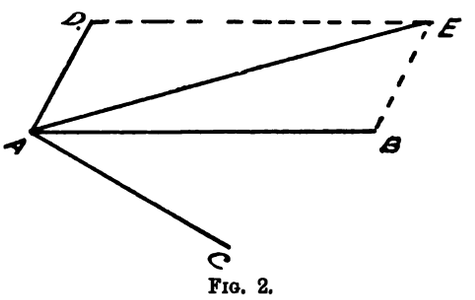

FIG. 2.

force due to it assists that due to the shunt winding, consequently with an increase in load we get a leading current, and, therefore, a rise in pressure; but in the machines under consideration the reverse is the case, for obviously the magnetomotive force due to the series winding is in opposition to that due to the shunt, therefore with an increase in load the field is weakened, the current lags, and the pressure falls, which will, of course, cause a battery to discharge which has previously been floating at the higher voltage. There is little to recommend this system except that it saves the cost of a reversible booster, and the pressure regulation is bad, and it is much better to use a reversible booster, for not only would the load on the generating plant be equalised, but the pressure would also be maintained constant.—E. AUSTIN.

*Answer to No.* 774 (*awarded* 7*s.* 6*d.*).—A compound-wound rotary converter with the series winding opposing the shunt is sometimes used on a traction load in conjunction with a "floating" battery—that is to say, a battery directly connected to the 'bus bars through switches, without a booster or any automatic arrangement for discharging it.

Digitized by Google

The usual regulating cells are, of course, a part of the battery, but are cut in or out by the switchboard attendant.

The method of working is thus. Under normal conditions from no load to about full load the rotary converter supplies the current to the line, but in the event of a heavy demand being made, the increased current through the series coil weakens the field, and causes the voltage to drop considerably. Simultaneously with the drop of voltage the battery begins to discharge, the rate of discharge increasing as the generator voltage become less—*i.e.*, as the demand for current increases. Thus the generator takes the load up to a certain point, after which it is relieved by the battery.

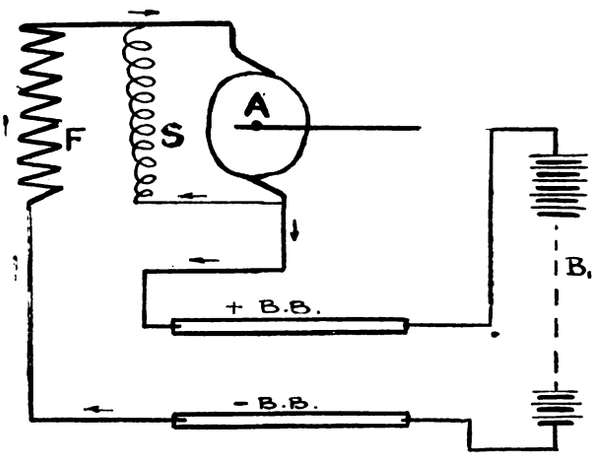

FIG. 1.

Fig. 1 is a diagram of the connections: B B are the 'bus bars from which the feeders may be taken. A represents the generator side of the converter, which is connected to the 'bus bars in parallel with the battery, $B_1$. S is the shunt winding and F the opposing series. Fig. 2 shows how the work may be divided between the generator and battery. The dotted line is the generator characteristic, the full line the combined characteristic of generator and battery. The shaded portion shows the watts added by the battery. The point at which the battery commences to take up the load should be slightly beyond the point at which the maximum efficiency of the generator is attained.

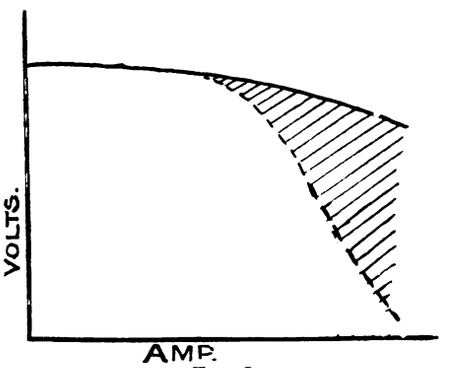

FIG. 2.

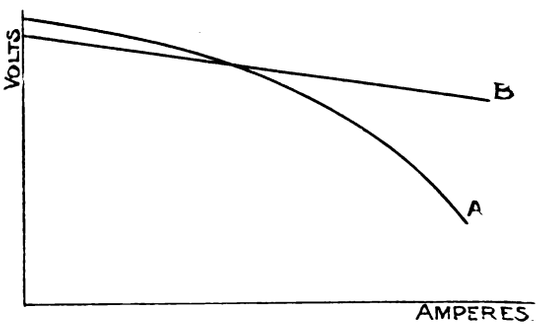
The advantage of reversed series coils for traction work is that the generator can be used in conjunction with a battery without any special boosting arrangements. Naturally, the line voltage is anything but steady, but on a traction load this is not always of such vital importance as to warrant the additional expenditure on plant necessary to obtain close regulation.—J. B. F.

*Answer to No.* 774 (*awarded* 5*s.*).—The purpose of the type of rotary in question is that it shall be used with a battery, thus working itself at a fairly constant load, the battery discharging at heavy loads and charging at light loads, the effect of using a reversible booster being obtained without the use of auxiliary machinery. If this type of rotary is installed throughout the system, the load on the main generating station will, of course, be kept very nearly uniform. The action of the machine is that at a certain predetermined load the series field exercises a weakening effect on the shunt field sufficient to lower the volts on the rotary and to allow the battery to discharge to the line. The load on the rotary being thus slightly relieved, the series field loses its predominance, and consequently the rotary supplies its normal output. In a carefully designed machine of this type the variation in the load on the rotary can be made very slight, and by using a diverter in parallel with the series field it can be adjusted to allow the rotary to work at different outputs, and for each different output be able to main that load very nearly constant, the line voltage, of course, being kept up by the battery. The rotary is simply a differentially-wound compound machine, and being differentially wound will not work at as good an economy as a cumulatively-wound machine, but the idea is that by sacrificing a little in the economy of the rotary and being able to do away with a reversible booster, that a higher total economy will be secured. An impression obtains in some quarters that the line voltage regulation on such a system would be very bad, but it would seem that this impression is owing to the fact of the machine having its series field energised by its own outgoing current and not by the line current, as in some types of differentially-wound boosters, being overlooked. In the first case the output of the machine is to a great degree self-regulating; the instant the machine attempts to supply anything above the predetermined load the series field at once checks it, and its normal load is resumed. In the second case the machine would not obtain any relief until the line load lightened, and the load might continue heavy for so long that the polarity of the machine would need a good deal of power from the shunt field when the load lightened to bring about normal conditions. In the first case the regulation of the machine is independent of the line load, and the only effect of the battery trying to back on to the machine is to weaken the series field, and thus tend to restore normal conditions. From the above description the idea of installing such machines will be understood, and also the fact that with the first method of energising the series field good regulation should be obtained.—W. T. W.

*Answer to No.* 774 (*awarded* 5*s.*).—In the station mentioned there is a battery installed in order to take any sudden rushes of current, and so prevent overloading the converters. The usual system is to instal a reversible booster to look after the battery, and in this case the machines would, of course, be compounded so as to keep



at approximately constant voltage. As this is a railway scheme, variations in voltage are not of much importance, hence it was decided to use machines with a large pressure drop, and to dispense with the booster. With this arrangement, when a heavy load comes on, the volts of the rotaries will fall off more rapidly than the battery, and hence the latter will take up most of the extra load. This will, perhaps, be better understood from the diagram, where A represents the characteristic of the machine and B that of the battery. Up to a certain point the machine will charge the battery, but if more current is required the battery will supply it, as the generator volts drop more quickly than the battery. The only advantage of the system is that no booster is required, and against this must be set the very bad pressure regulation. I do not know if lights are run off the traction mains, but if so, I should imagine they would be very unsteady.—H. C. H.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

780. How would you arrange the Hopkinson test and determine the efficiency on two 900-kilovolt-ampere 500-volt compound generators or machines?—F. V.

781. Describe with sketch the best vat to use for loading a 600-kilovolt-ampere 400-volt generator.—F. V.

### ANSWERS.

*Question No.* 775.—A leading stoker in a certain central station is suspected of inefficiency. How can I tell whether he is getting the full duty out of his working boilers before putting in another on a rising load?

*Answer to No.* 775 (*awarded 7s. 6d.*).—Central-station engineers are now turning their attention to the boiler-house more than they used to do, with a consequent reduction in the number of pounds of coal burnt per unit generated. A boiler-house may be full of the most up-to-date arrangements and automatic appliances, and yet the coal bill will be excessive if the stokers themselves are inefficient. As a rule, so long as a stoker keeps a steady pressure on his boiler nobody troubles him, but this is not enough. A stoker, in order to secure for himself the minimum of exertion and avoid words with the shift engineer about the pressure, is tempted to have more boilers working on the steam range than he should do, and also to put on another boiler before it is actually required. This practice results in large radiation losses, which under ordinary conditions amount to as much as from 5 to 10 per cent. If a boiler is worked under its full power, the amount of loss due to radiation will be the same as if was doing its full output, because the temperature of the steam is not altered. A boiler working at half its capacity will, therefore, lose twice as much by radiation as if it were doing its full share of work, speaking in regard to the amount of work done. If a boiler is overworked, the relative loss by radiation is very much reduced. It will thus be seen that for efficient working it is most important to keep the number of working boilers as low as possible.

Let us take the case of the average large central station, where the coal is fed by shutes into hoppers attached to the boiler front, and moving firebars are fitted to prevent the formation of much clinker. The inefficient stoker puts 10 boilers working on a certain load for which eight would be quite sufficient. The steam pressure will not cause him much anxiety, as the 10 boilers would manage any sudden peak that came on without being pushed at all. With only eight boilers on he would have to keep his fires the right thickness, and a sudden rise in the load would mean considerable poking and slicing of the fires so as to keep them quite clear of clinker and working at their full capacity. He would also have to avoid feeding much water into the boilers when they were being pushed, so as not to lower the temperature. A good stoker will not start up another boiler for every increase in load if he thinks the increase is only a temporary one. He will know from experience how many boilers are required for certain shifts, and on those shifts get the required number either working or ready with fires banked up for putting on the range. Mr. Bryan Donkin mentions a test where four good stokers were put to fire the same boiler—a two-flued 30ft. Lancashire—under the same conditions. There was a difference between the most and least expert of 23 per cent. in capacity and 18 per cent. in economy, a saving of £7 to £8 per week with coal at 10s. a ton.

I will now describe a method of comparing the efficiencies of the leading stokers which is used in an up-to-date large central station. In order to find out how much coal each stoker uses on his shift, the shutes for each boiler are fitted with an arrangement whereby, when the hoppers require filling, the stoker pulls a handle, and a known quantity of coal falls into the hopper. A meter is attached to the handle, which registers how many times the shute is opened. There are different methods of weighing the coal; the one described above is a very common one. Each stoker as he goes off shift takes the readings on the dials of the meters, and notes the numbers of the boilers that have been working.

Name of stoker. ..... Date.....
..... Time.....

| No. of boiler working. | Time On. | Time Off. | No. of pumps working. | Time On. | Time Off. |
|---|---|---|---|---|---|
| | | | | | |

Meter readings.
Coal..... Water.....

FIG. 1.

In Fig. 1 is shown sheet that stoker has to fill up on each shift. The switchboard attendant takes the number of units generated at the end of each shift, and works out the number of pounds of coal and water per unit generated. The various shifts can thus be compared. A good plan would be to mark on the day's load curve when each boiler was put on. Do this for three weeks when similar loads are experienced, and it will at once be seen which stoker is the most conscientious worker.

In Fig. 2 I give some actual results obtained in a central station having a good day load. It will be noticed that the figures obtained for the night shift are always higher than those during the day, and that the highest figure is obtained on the Sunday morning. This is owing to the very small load on at these times. To compare one stoker with another, compare them on similar shifts and with the same boilers working, as boilers, though of the same size, vary very much in their steam-raising qualities. Also watch that the readings are taken at the *end* of the shift, not half an hour before. If the stokers know there is a test on, an artful one will use almost every bit of coal on his fires, and the man following him will have to use a lot of coal immediately to keep up the pressure.

FIG. 2.

A $CO_2$ recorder is most useful in a boiler-house to ensure efficient working, and will almost certainly pay for its cost

Digitized by Google

in the first six months. The firemen can then see for themselves whether there is too much air passing through the furnaces. Mr. R. S. Downe in a paper recommends a bonus system for the stokers that he has tried with success at Southport. Certainly a small monetary reward will have a great effect on the way a stoker looks after his boilers.—W. A. T.

*Answer to No.* 775 (*awarded* 7*s.* 6*d.*).—"W. E. O." gives absolutely no particulars of his boiler-house, and, therefore, only general and not particular advice can be offered to him. In the first place, let him learn to fire and get a thorough understanding of the combustion of coal as applied to steam-boilers, for nothing is so efficacious to economical working as a skilful and intelligent operation of the boiler plant. He should ascertain the amount of evaporation his boilers will easily give under the conditions normal to his station, and should also know the amount of water used per kilowatt-hour in the station, including all auxiliary plant and unavoidable losses. He will then by comparing the load demanded with the number of boilers in service be able to form a very good idea of how things are being worked; he must not, however, think that the man who works with the fewest boilers in service is getting the most economical results, for this by no means follows. For instance, suppose he has a plant of 11 Lancashire boilers set in the usual manner, and that with the present load he can just manage with six boilers in service. The load, however, is rising, and he will require at least two other boilers to get through the heaviest part of the load, and for at least an hour will have to force all eight boilers to get through. Then he must have, in order to be safe, another boiler up to or nearly up to pressure under banked fires, so as to safely meet a breakdown on any one of his boilers. Now, with Lancashire boilers especially, one boiler keeps its fellow warm, and radiation losses are thus to a great extent minimised, so that it would be by far the best policy in this case to work with nine boilers always in service, and for the following reasons: A boiler, unlike an engine, works best at an easy load—each 1lb. of water evaporated is evaporated at a more economical rate than if the boiler was pushed—priming is avoided, the life of the boiler is prolonged, there is a good reserve of power in case of sudden calls occasioned by sudden and severe overloads, the amount of feed water necessary to be fed to the boiler is reduced to a minimum, with consequent good effect on the economy of operation and life of the boiler and consequent on the fires not having to be pushed, there is time for complete combustion (or as nearly complete as is possible in practical working) to take place. The best test, of course, to apply is to note the amount of coal used by each leading fireman on similar loads and under similar conditions; but it is quite easy for an engineer not thoroughly conversant with the best methods of working his plant to so work matters in the engine-room that the fireman receives blame for what is not his fault. In many stations using reciprocating engines, the engineers pride themselves on maintaining a 27in. vacuum. Now, the economy to be obtained by a 27in. vacuum over a 25in. or 24in. vacuum on reciprocating engines is decidedly small, but the increase of power required to obtain this increase of two or three inches is considerably over 75 per cent., and if the condensed steam is used again for boiler feeding the evil is still further aggravated, as the hot-well temperature is greatly reduced and more coal is required to be burnt in the boiler furnaces (owing to the influx of cold feed) than is necessary. The above instance will show how without exact particulars of the plant it is impossible to give any definite rules for working it at its highest economy. In conclusion, the leading fireman who is continually on the trot, and whose men are always sweating, is no good; the skilful and economical fireman is always able to manage his work without killing himself, and with time to sweep up round the boiler and keep things tidy.—W. T. W.

*Answer to No.* 775 (*awarded* 7*s.* 6*d.*).—The surest way of checking the leading stoker in question would be to measure the amount of water *actually used* during a certain time by the boilers under steam. A short test of, say, a quarter-hour or half-hour's duration would be sufficient. The evaporative capacity of the working boilers being known, it would be seen at a glance whether or no full evaporative duty was being got out of them. It is hardly necessary to point out the importance of having the level of the water in each boiler at exactly the same mark at the finish as at the start of the test. The quality of coal used should also be taken into consideration, and, if poor, allowed for.

By inefficiency, it is presumed that the stoker in question cannot work his boilers to the same advantage when working under the same conditions as the other stokers. It is the exception rather than the rule to find two (human) stokers who possess even in a small degree the same firing characteristics. This is more marked in the case of hand firing, and with machine stoking the writer has never known two firemen to work their boilers and stokers alike, even with men on shift together, and working under precisely the same conditions of load, etc., and using the same quality of coal; and, with few exceptions, firemen as a rule refuse to accept makers' instructions as to the best methods of working their machines, preferring, instead, to work on lines of their own; especially is this so when one has to deal with men who have been used to hand firing for 10 or 15 years.

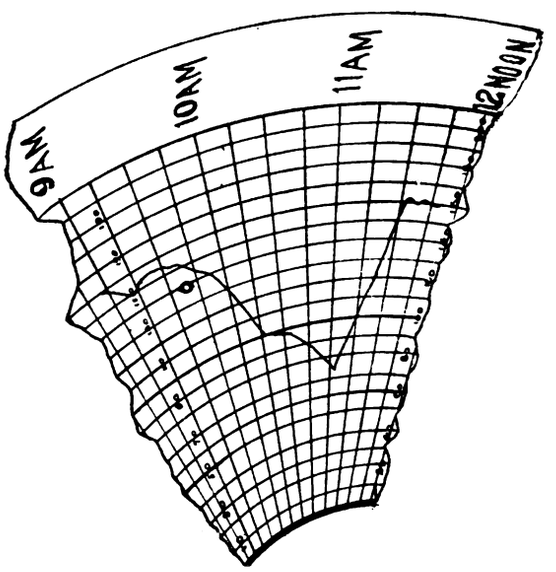
In many lighting stations, particularly those where the areas supplied are mainly residential, the evening load (which is usually the heaviest) can be gauged from year end to year end to such a nicety as to make it almost possible to draw up a table of times for putting in boilers, starting engines, etc. In the case of large stations with variable loads, such as combined lighting and traction stations, the working conditions are, of course, different, and it does not always pay to leave the coupling up of additional boilers until the last moment. Boilers, when properly fitted with isolating valves, can be coupled to the range at a few pounds below working pressure a short time before being allowed to steam, thus obviating the risk of getting "steam bound"; this plan is advisable where superheaters require to be drained before opening out the boiler to range. The writer knows of at least one case of cracked cylinder covers owing to insufficient draining in the hurry for steam. Nearly all types of machine stokers have forced or assisted draught arrangements, usually in the form of a number of steam jets; in fact, two well-known makes of machines depend entirely on their forced-draught attachment for their excellent steam-raising qualities. The nozzles or holes in the jet pipes should be examined frequently, as they are very apt to become stopped up. With the chain-grate type of stoker it is most important that the grate be kept well covered with fuel in order to prevent any inrushes of cold air, which would otherwise work through the grate if the fire was allowed to get patchy or broken. If this type of stoker is used and the boilers are grouped in pairs with side passages between adjacent pairs, a peep through the small inspection doors will soon show whether the fires are being worked properly or not.

In all well-appointed stations periodical evaporative tests are regularly made on the boilers, usually after being laid off for cleaning, as where large contracts for coal extending over six or twelve months are given it is most important to know that the coal supplied is being kept up to specification, as it is not an uncommon occurrence for coal to vary in quality, usually on the poor side for the station. In some large stations where the boilers are hand fired, the firemen work on similar lines to the system in vogue on many large liners. The firemen all work their fires together at given signals from the leading stoker. This system possesses many bad features, and does not help to solve the smoke problem. The writer has found it a good plan on a rising (evening) load to run the water in boilers up to about seven-eighths glass, and has many times thus got over the "peak" without the usual extra boiler.

By paying close attention to the methods of working his boilers and noting generally the amount of intelligence the fireman puts in his work, "W. E. O." should soon find out whether the man is worthy of his hire or not. But, as before mentioned, it is seldom of much use to set up one fireman as a standard for the others to follow, and it does not always pay to change hands too often; new firemen invariably require initiating into their work at the added expense

Digitized by Google

of a few tons of coal. The bonus system has been introduced in several large stations with the object of getting the best out of the boilers and firemen, but it can hardly be said to have proved a success. If kept in good working order, a $CO_2$ recorder soon pays for itself. A draught gauge should always be provided, as it is an indisputable authority at times when the fireman most emphatically declares "that the draught is bad." A recording steam pressure gauge is (in the writer's opinion) an indispensable instrument to every central station. It is, however, advisable to keep it under lock and key for obvious reasons. The sketch shows



a part record—pricked from the original chart—which proved to be the undoing of a very careless fireman. The boiler was steaming at about half its normal load, but the fireman could not get the steam on the rise. The engineer-in-charge then took the boiler in hand himself, and, as shown on the chart, brought steam back to normal within half an hour. The sharp rise in the curve makes it hardly necessary to add that the boiler was of the water-tube type, and fitted with chain-grate machine stoker.—S. L.

*Answer to No.* 775 (*awarded* 5*s.*).—It would be more than a difficult question to determine, by any fixed rules, the capability of any stoker in charge of boiler plant. But observation coupled with knowledge of the capability, so to speak, of the plant under his control should enable a charge engineer to readily determine the question set. The steaming capacity of the boilers and the steam consumption of the engines should be known to all in charge—not the theoretical, but the ordinary practical figures. An engineer knowing the station load and its likelihood should know how many boilers he requires—it is a matter of predetermination. If the stoker be incompetent an observant engineer should easily see his weakness, for, except in cases of sudden rushes of load, a boiler-house works under absolutely uniform conditions, or should do so. A skilled man, by a glance at the fires, should detect bad firing; the pump speed is a matter of experience and its variation a factor which every charge man should be aware of. Water-meters, gas-recorders, and the like make for efficiency, but they should be of more use in determining defects in machinery than incompetency in workmen. If an incompetent stoker cannot be detected by the observation of what work is being done, and the knowledge of what ought to be done, it would seem that not only is the stoker at fault, but that the charge engineer is not free from blame.—S. E. T.

*Answer to No.* 775 (*awarded* 5*s.*).—In the central station to which the writer has the pleasure to belong, the capacity of each boiler is reckoned out in amperes at the mean 'bus-bar pressure on the assumption that each unit requires 30lb. of steam. Thus, supposing the boiler to be capable of evaporating 10,000lb. of steam per hour, by dividing by 30 we get the equivalent units—viz, 333 or 333,000 watts—and this again divided by the mean 'bus-bar pressure, say 450 volts, gives us 740 amperes. By this means the engineer in charge can tell by a glance at his ammeters how near he is running to the capacity of his boilers, and a competent fireman should have no difficulty in maintaining his steam at the proper pressure under ordinary normal working conditions if this load be not exceeded. On a rising load it is well to get on another boiler half an hour before it is actually wanted, as more coal is used by fixing boilers than by working easily with an additional boiler for a short time. By employing this method no difficulty is experienced as to the time a boiler should be put on to the main, and by reference to the load curve of the same or a similar day of the previous week the writer has been able to go round to the boiler-house before the evening load comes on and instruct the leading fireman as to the exact time each boiler is to go on and come off.—J. M. A. M.

*Question No.* 776.—A four-core telephone cable 4½ miles long connects a sub-station to a generating station. The cores are twisted in pairs and used as two separate telephone lines. It is required to put up a pair of single-stroke bells, one at either end, to be worked by means of Morse keys in order to signal from generating station to sub-station, and *vice versâ*. Can this be done with existing cable, without interfering with the proper working of the telephones? If so, how? If not, why not? The resistance of the line (lead and return) is 350 ohms.

*Answer to No.* 776 (*awarded* 7*s.* 6*d.*).—Yes; this can be accomplished in several ways without interfering with the present telephone circuits, but the precise arrangement would be dependent on conditions not stated in the question, and which I therefore propose to assume in discussing a few ways of making a successful arrangement. From the question I understand that the two separate telephone circuits also includes two telephones at each end, with the probability, therefore, of simultaneous conversation on each pair of wires. It is thus obvious that any arrangement for signalling purposes should not include any combination of the two circuits if an high efficiency of working is desired. Such a combination would cause more or less cross-talk and strong induction from adjacent power cables. The question is now simplified: the two signalling circuits must be kept distinct, and each connected one to each separate loop. We may now only consider the case of one loop and the signal in one direction only, as the other loop and return signal is merely a reverse arrangement.

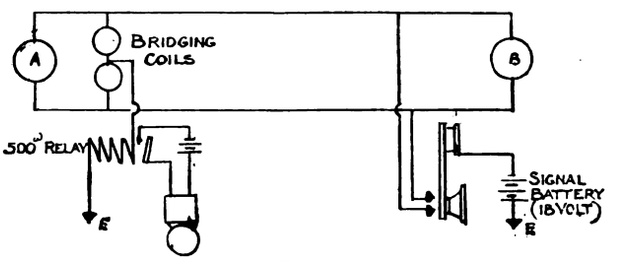


FIG. 1.

Now, is it required that conversation shall be possible whilst signals are being sent? Assuming the simplest case first, where it is not desired that conversation shall take place at the same time, then Fig. 1 will be seen to meet the case. At end A, where signals are to be received, we have shunted across the loop a pair of bridging coils of 600 ohms each in series with each other. These coils should preferably be iron cased, because of the higher impedance offered to the shunted fluctuating speaking currents than where simple resistance coils are used. Branched from the middle of these two coils is a single make-and-break relay of 500 ohms resistance, with its other terminal joined to earth. This balanced earth, having 1,100 ohms interposed between itself and either line wire, will present no inductive effects, and is, in fact, a method adopted at certain exchanges for trunk clearing. The single-stroke bell is now joined up with its own separate battery to the local contacts of the relay, and should be kept as a separate circuit from the other apparatus. At the B end, one of the two lines is branched on to the under contact of the Morse key, the spring of which is joined to an earthed battery. If we combine two keys together to make two under contacts, both line wires may be branched to these, thus reducing the resistance in the signalling circuit. If the relay is operated by a minimum current of 15 milliamperes, then a battery of about 18 volts will be required, but where only

Digitized by Google

one under contact is made use of, a battery of 22 volts will be wanted.

Considering now the other case, where it is required that the transmission of signals shall not interfere with conversation taking place at the same time, it is seen in Fig. 2 that it is necessary to balance the signalling battery at B end, exactly as we have already done with the relay. Two similar bridging coils of the same resistance are used, and the Morse key under contact is connected to the middle point, the spring being, as before, connected to an earthed battery. When the key is depressed the current divides equally through the coils, passes along both lines, through

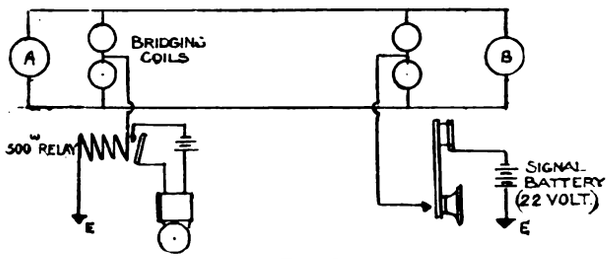

FIG. 2.

the distant coils, and rejoining at the relay, passes through the latter to earth. The resistance in the signalling circuit is 1,450 ohms, and with the same relay efficiency as before a battery of 22 volts would be required to operate it, exactly the same voltage as in the last case, but with the advantage of simultaneous signalling and speaking. The writer has had under his notice an arrangement very similar to this, and is confident that "J." will experience no trouble if he adopts the system I have just described. He will find it equally applicable to either a battery or magneto system.

The following arrangement is an exceedingly simple one, and has been experimentally tried where a magneto system with low-resistance telephone bells of 100 ohms each is in use. At the end where signals are required, a two-ohm relay is placed in series with the line as in Fig. 3. At the B end the Morse key is connected so that it may substitute a battery for telephone when depressed, in which case the current will pass through the 100-ohm bell and the two-ohm relay. If the latter has an efficiency of about 60 milliamperes, it will require a battery of 30 volts at the other end to operate it. As before, the local contacts are joined

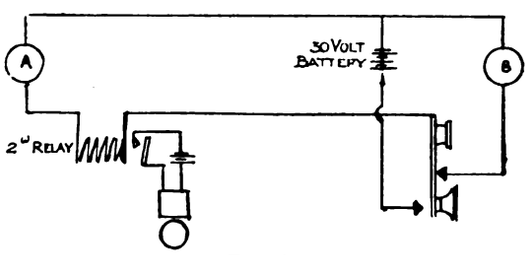

FIG. 3

to the bell and separate battery. The passage of generator currents through this relay will not cause trouble, owing to the frequency of the current and the inertia of the armature. The latter will slightly vibrate as a consequence, but the rapidity of the alternations prevent it from closing the local contacts. The success of this system, however, will depend on the local conditions not stated in the question. If the bells are of higher resistance than 100 ohms, the battery of 30 volts would have to be increased. This would then compare unfavourably with the system I have recommended, which has the additional advantage of being able to give signals without interfering with any conversation taking place at the same time.

In conclusion, it would not be out of place to briefly mention that if "J.'s" telephones are of the magneto type, he could superimpose a third telephone circuit by the use of translators. This, of course, would present greater advantages than the signalling circuit asked for. As it is beyond the question, I will not discuss it further, but if "J." desires to know more of this I shall be glad to oblige him.—F. RADCLIFFE.

*Answer to No.* 776 (*awarded* 7*s.* 6*d.*).—It is perfectly practicable to arrange the terminal conditions of the two pairs so that single-stroke bells may be introduced at each end and worked by Morse keys without any disturbance to the telephonic working. To effect this it is necessary to employ a special form of induction coil, known as a transformer, the function of which will be readily seen by con-

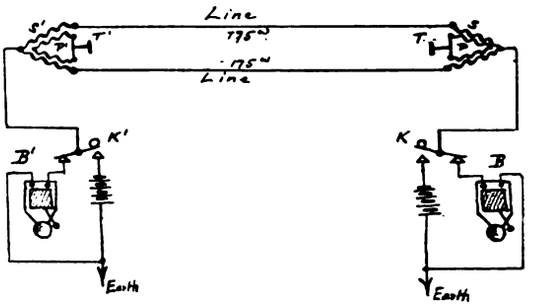

FIG. 1.

sidering the manner in which it is introduced, as shown diagrammatically in Fig. 1, where the connections of only one pair of wires are shown. T T′ are the telephone sets at the respective ends; S P and S′ P′ the transformers; K K′ the Morse keys (single current); and B B′ the single-stroke bells. The internal connections of the transformer, which is of the Hedgehog pattern, are shown clearly in Fig. 2. The line and earth (or return) wires of the telephone set are joined to P and P′. The two lines of the particular pair considered are similarly connected to S and S′. The resistance of the primary and secondary coils of the transformers are the same—viz., 150 + 150 ohms each. The resistance of an average pattern of single-stroke bell is 100 ohms, and the current required varies from a minimum of 45 milliamperes to 100 milliamperes. Estimating for a current of 80 milliamperes,

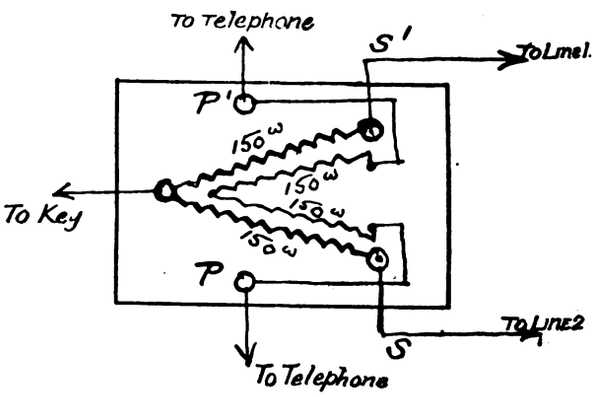

FIG. 2.

and noting that the total external resistance is $\frac{150+175+150+100}{2} = 288$ ohms approximately when either key is depressed, we may determine the battery power required from the expression $C = \frac{ne}{nr+R}$, where $n$ is the number of cells, $r$ and R the internal and external resistance, and $e$ the E.M.F. of a single cell. If Leclanché cells are used with an E.M.F. of 1·4 volts and an internal resistance of one ohm per cell we have $\cdot 080 = \frac{n \times 1 \cdot 4}{n+288}$, from which $n = 17$ cells. The system outlined above is coming largely into use in methods of combined telegraphy and telephony where "superposition" is found to give excellent results.—A. F.

[Other replies to Question No. 776 will be given in our next issue.—ED. *E. E.*]

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

### QUESTIONS.

782. I want to connect a booster in circuit with one of the feeders in an alternating-current single-phase station, 2,000 volts earthed return. Should it be connected to the earthed or unearthed main, and why?—G. E.

783. Certain motors and generators are fitted with a continuous ring, connecting all pole-shoes together. What is the object of this ring, and what is its effect on the working of the machine?—W. M.

784. The system known as the free-wiring system has now been in vogue in certain towns for upwards of five years. How does it satisfy (1) the consumer; (2) the supply company; (3) the local contractor; and how are difficulties caused through tenants leaving and the new tenants refusing the use of the light adjusted?—W. T. W.

### ANSWERS.

*Question No.* 776.—A four-core telephone cable 4½ miles long connects a sub-station to a generating station. The cores are twisted in pairs and used as two separate telephone lines. It is required to put up a pair of single-stroke bells, one at either end, to be worked by means of Morse keys in order to signal from generating station to sub-station, and *vice versâ*. Can this be done with existing cable, without interfering with the proper working of the telephones? If so, how? If not, why not? The resistance of the line (lead and return) is 350 ohms.

*Answer to No.* 776 (*awarded* 5*s.*).—The answer to the above question, so far as the possibility or impossibility of working the two bells by means of the wires already in use is concerned, is a decided affirmative, although as to the method of satisfying the requirements of the question much depends upon the circumstances and conditions of working, as well as upon the type of telephonic instrument, with its necessary connections, which is in use at the present time. One of the chief difficulties encountered in solving this problem is found in the lack of definite information as regards the type of telephone in use—that is, whether it is of the battery or magneto type. That such is the case is readily seen when it is pointed out that a system applicable to one type of telephone may be wholly unsuited to the other type, on account of the existing difference in the internal and external connections. For the sake of exemplification, therefore, we will here assume that the battery system is in use, and, following this, will treat of several methods whereby the above requirements can be fulfilled.

*Method No.* 1.—This method will no doubt be one of the simplest methods which can be adopted, and, if proper precautions are taken, there appears to be no reason why it should not work satisfactorily, without interfering with telephonic intercommunication. In Fig. 1 will be found a diagram of the necessary connections for the bells, with wires leading to the two telephones. For the sake of reference the following index of parts has been drawn up: B C is a battery of cells, whose E M.F. is about 30 volts; M is a Morse key; D is an ordinary single-stroke bell; E is an earth connection; A and B are the two stations respectively. Consulting Fig. 1, we see that only one wire is used for the bells, whilst the earth acts as a return for the current passing through *either* one of the two bells. When it is required to communicate from either end of the system to the other, the key, M, is depressed, with the result that a current traverses the battery, line wire, A′ B′, bell, D, and the earth, E, returning to the same battery, This, however, can only be the case when the telephones are not being used, and it is presumed that the bells are not required when the telephones are in use, but only when they are out of use. Certain precautions must be taken, or else complications will arise and unsatisfactory working result. In the first place, it will be observed that between the points A′ and B′ there will be a difference of potential when the telephones are being used, and this difference of potential will tend to send a current through the two bells and the earth; if the tendency becomes an actuality, then the bells will ring and false signals will be given. Now, although this difference of potential may not reach more than 20 per cent. of the voltage of the telephone system, depending upon the peculiar circumstances of the case in question, yet it is advisable to reduce this tendency to its smallest limits. To effect this, the bells should each have at least a resistance of 1,000 ohms, whilst a still higher resistance would not be out of place or beyond reason. If this precaution be made, then the two bells will not ring when the telephones are working, because the current passing round the coils of the bell will be too small to be effective. Another precaution which should be made is to make sure that the insulation of the system is good, for if

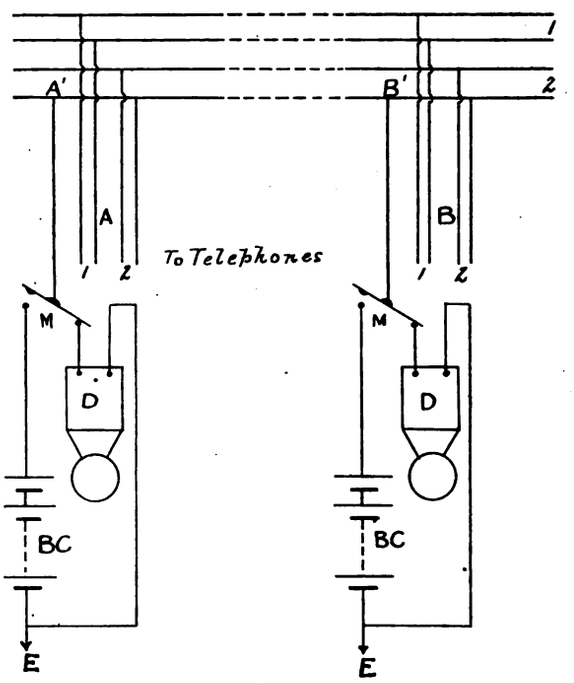

FIG. 1.

this is not the case, then earth leakage currents will pass between the bells and the telephones, causing sad havoc to be made of any communication which may be in progress.

*Method No.* 2.—This method is differentiated from the above, inasmuch as the earth return is displaced by a line wire return. Fig. 2 shows a wiring diagram of this method, indexing being the same as in Fig. 1. As will be seen from a perusal of the figure, two lines are used, one from each of the two telephone systems, thus interconnecting

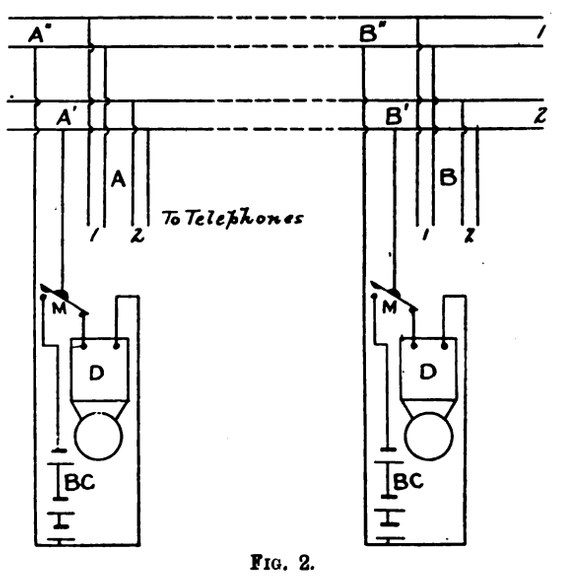

FIG. 2.

these two systems through the two bells. The method of procedure in this case is precisely the same as in the above, the function of the earth being performed by the newly introduced line. In this method, too, the resistance of each bell should be at least 1,000 ohms, this being increased if possible. The increase is more necessary here than in the preceding method, because at times when the two telephone systems may be in use simultaneously there will be two differences of potential acting together

Digitized by Google

on the bells, tending to send double the current round their coils. Therefore, if possible, use a resistance of 2,000 ohms for each bell, and, if practicable, a slightly higher battery voltage than 30 volts.

In the above it has been assumed that no bell signalling is required when the telephones are in use. If, however, bell signalling is required then, or at *any* time, it is clear that the above methods are of no use, and it is feared that no reasonable and simple method is, without introducing fresh line wires. Concerning the above two methods, it may be found that greater practical convenience and more satisfactory working is secured by introducing a relay into each bell circuit, and then the connections and wiring must be altered accordingly.—G. W. B.

*Answer to No.* 776 (*awarded* 5*s.*).—The question states that the cores are twisted in pairs and used as two separate lines, so I presume they are as shown in Fig. 1. If the

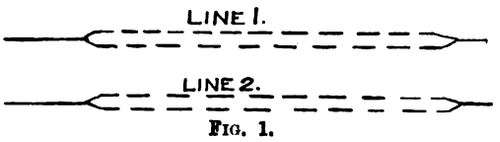

FIG. 1.

wires were connected in this way it will give a larger sectional area of copper, and therefore offer less resistance than if they were separate. As there is a considerable distance (4½ miles) for the current to travel, a relay will be required. Fig. 2 is a diagram of connections of two single-stroke bells, with telephone connections, that I have working every day, and they give no trouble at all. The telephones are the ordinary watch pattern type. I suppose the telephones in question will be of the humming transmitter type. This type will even work better on a bell circuit than the watch type, on account of the induction coil. As the receiving circuit is connected across the ends of the secondary of the coil, this reduces to a minimum inductive disturbances, which are generally a trouble in the watch type. I presume the signalling for the telephones will be done by the single-stroke bells, therefore a certain call will be necessary when telephone communication is required. A switch is put in the telephone circuit to cut

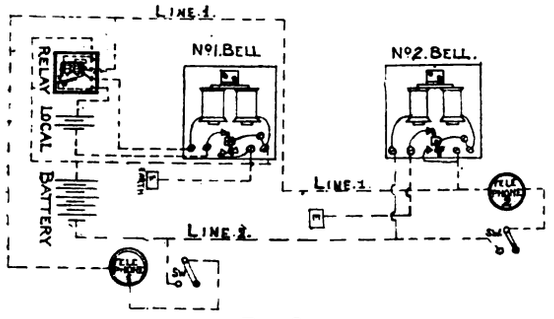

FIG. 2.

the telephone out when not in use. This arrangement, if tried, will be found to give every satisfaction.—J. P. S.

*Question No.* 777.—What is the customary limit of density of current (per square inch sectional area) in feeder cables? In what degree is the limit affected by the proximity of other feeders, or by the nature of the coverings, both protective and insulating? The reason for asking this question lies in the observation that a feeder (carrying 1,000 *a* per square inch during a breakdown of another feeder) became heated to such an extent as to alarm the workmen and jointers who were repairing the defective cables and had exposed the sound feeder. The feeders are lead and paper covered copper cables laid in tarred sand in wooden boxes.

*Answer to No.* 777 (*awarded* 7*s.* 6*d.*).—It is impossible to state whether the current density of the cable in question had exceeded its assigned limit, because this current density is by no means a constant, and varies greatly. Let us consider a cable $d$ inches diameter conveying a current C amperes. The area of the cable is $\pi d^2$ square inches and its current density is $\frac{C}{\pi d^2}$ amperes per square inch. Its cooling surface per inch of length is $\pi d$ square inch. Now let us double the area of the cable and find the ratios of the cooling surface in the two cases per ampere with the same current density. With diameter $d$ the cooling surface per ampere $= \frac{\pi d}{C}$. With area $2\pi d^2$ the diameter of the new cable will be $\sqrt{2}d$ and the cooling surface per inch length $= \pi\sqrt{2}d$. The current is now, of course, 2 C. Therefore, the cooling surface per ampere is now $\frac{\pi\sqrt{2}d}{2C} = \frac{\pi d}{\sqrt{2}C}$ Thus we have considerably reduced the cooling surface per ampere. Therefore, to work with the same maximum permissible rise in temperature of the cable, we shall have to reduce the current density in the larger cable.

Now, when the temperature of a cable has assumed a steady condition, the amount of heat generated and the amount radiated and conducted are equal. Therefore, the nature of the surrounding soil and the depth in the earth the cable is buried will play an important part in this question. If the surrounding earth is moist, the heat will be conducted away quicker than if the earth is dry. I am of the opinion that the sand in which the cable in question is laid will prove very non-conducting, and thus render the temperature of the cable higher than it would ordinarily be.

Four years ago the principal German cablemakers attacked this question, and a committee was formulated with a view to conduct experiments to decide this question. These experiments were conducted on cables buried in the garden of the Munich Laboratory. After long experiments they adopted a formula which was found to give results very much in accord with experiments, as follows:

$$\frac{qt}{J^2} = \frac{1}{C^2} \log \frac{4h}{d}$$

where $d$ = the diameter of the cable;
$q$ = the cross-section in square millimetres;
J = the current;
$t$ = the temperature rise (degrees C.);
$h$ = the depth of the cable below the surface of the earth;
C = a constant the mean value of which as the result of many experiments was found to be 11.55.

The maximum permissible temperature rise can be taken as 25deg. C. above the earth, giving an actual temperature of 40deg. C. on a hot day. Supposing the cable to be laid at a depth of 700mm. and that only go and return are considered, the following figures may be taken as giving the loads cables can carry: A cable of 16 square millimetres section will carry 140 amperes, of 50 square millimetres 260 amperes; of 95 square millimetres 370 amperes, of 150 square millimetres 475 amperes; of 310 square millimetres 705 amperes, of 500 square millimetres 920 amperes; of 625 square millimetres 1,040 amperes, and of 1,000 square millimetres 1,350 amperes. These results are the latest and most accurate to hand, and are being put into practice by the leading cablemakers. The question also asks whether the limit of current density is affected by the proximity of other cables. Most certainly it is, as it will be seen that a greater amount of heat has to be conducted away by the earth in proximity to the cables. This will mean an increase in the temperature of the cables. In the above experiments it was found that in such cases the loads given must be lowered by 25 per cent. The nature of the coverings has very little effect on the current density.—ERNEST P. HOLLIS.

*Answer to No.* 777 (*awarded* 7*s.* 6*d.*).—The current density of an insulated cable is limited by the maximum safe rise of temperature which takes place due to the $C^2R$ losses in the conductor. An insulated conductor dissipates this heat by radiation and convection from its exterior surface of insulated covering, and, therefore, the maximum current density depends partly on the nature of the insulation—*i.e.*, how far this will stand heat without deteriorating—and partly on the disposition of the conductor with reference to its surroundings—*i.e.*, the amount of surface exposed for radiation and the heat-conducting properties of the surrounding materials. In the old days it was sufficient to say that the maximum current must not exceed 1,000 amperes per square inch of conductor area, and this rule is often found in use now. It is obvious, however, that this is not true for all sizes of conductor, for it does not take into consideration the *sine quâ non* of the whole problem

Digitized by Google

—*i.e.*, the maximum safe heating effect of the current. As a matter of fact, it is too small a current density for small insulated conductors and too large for heavy conductors when laid in the usual way. For the same current density it is obvious a small conductor will not get so hot as a large conductor, for its radiation surface is larger in proportion to its area.

Kennelly found that the rise of temperature which should govern the maximum amperes carried varies nearly as the square of the current for any given wire, and that the square of the current varies as the cube of the diameter of the wire. He published a table based on the rule laid down by the I.E.E, that "the sectional area of any conductor should be so proportioned that if double the current be passed through it the temperature of such conductor shall not exceed 150deg. F.—*i e*, assuming an average temperature of 75deg. F., then the *rise* of temperature shall not exceed 75deg. with double the normal current. The rule following expresses this:

$$d = \cdot 0147 \sqrt{C^2},$$

where $d$ is diameter of conductor in inches and C the current in amperes.

I have found from experience of town feeders that the I.E.E. rule regarding current density is safe and reliable for feeders laid in the ground. This rule is as follows:

$$\text{Log } C = \cdot 82 \log A + \cdot 415,$$

where C = current in amperes and A = area in one-thousandth of a square inch. This gives a maximum rise of about 20deg. F. on large sizes, and is a good practical rule, which I take it is what the enquirer wants.

In order to see at a glance what is the correct maximum density for all sizes of cable, I give the following table calculated from this rule. I have also added in a separate column the density in accordance with Kennelly's rule.

| Sectional area of conductor in square inches. | Maximum current in amperes — According to I.E.E. formula. | According to Kennelly's formula. |

—DUPLICATOR.

*Answer to No.* 777 (*awarded* 7*s.* 6*d.*).—It is a difficult matter to fix a limit for the current density in a cable. As the case quoted is a special one, the feeder being loaded up owing to the breakdown of another feeder, it is possible to neglect the question of the economical current density and drop of pressure, and to consider only the maximum current density admissible without heating the cable to such an extent as to cause damage. The result of passing a heavy current through a cable might be a temporary or a permanent weakness, in the former case the insulation resistance becoming less for the time being, and improving again to its normal value under normal conditions; and in the latter case, the insulation resistance becoming less permanently, and either breaking down during the time the extra stress is on the cable, or at some future time.

The extent to which the insulation of a cable is impaired depends upon the value of the current and the time the current is passing, and the pressure will considerably influence the result in the case of an excessive current. It is quite possible for a very large current to be carried for a short time without doing any damage, as the cable will take some time to heat up, but as the temperature of the cable increases, the insulation resistance will fall to a greater degree. Thus, in the case of a temporary weakness, no actual damage would probably be caused, owing to the current not reaching an excessive value or only being excessive for a short period, not sufficiently long to distort or physically damage the insulation. In the case of a permanent weakness, however, the insulation may be so distorted, either due to the heat alone, or due to the failure of the cable mechanically, or the properties of the insulation may be completely altered, and in most cases the insulation would become dried up or charred. It is possible that neither of these faults would show on an ordinary insulation testing set of the usual voltage, and in the case of low-pressure cables there might be no actual breakdown for some time, but in the case of high-pressure feeders it is probable that the cable would break down at the time or when the current again reaches a high value, or should a sudden rise of pressure occur.

The damage liable through overheating varies with the class of cable, but a few instances might be mentioned. With vulcanised bitumen cables probably a permanent set would take place owing to their mechanical weakness; with rubber cables, the rubber would be impaired and charred, and the author has seen cases where rubber or rubber composition has become quite hard and brittle; whilst with fibrous cables impregnated with compound (such as paper cables), the compound may be caused to run or volatilise and the insulation to dry up, the mechanical protection remaining perfectly good, and these cables would probably suffer more damage than those of the other classes. Damage may also be caused at the joints, but if these are well made, and the cross-section of the connectors sufficiently large, they should stand as much or even more current than the cable.

The best condition under which a cable can work, as regards heating, appear to exist when the cable is as free as possible, and if other cables in proximity are sufficiently far away for the heat generated by them to be dissipated without affecting the temperature surrounding the cable carrying a heavy current, the carrying capacity of the latter will not be affected, and, *vice versâ*, a cable in a position where it receives heat from the exterior will not carry such a heavy current as one which only has to dissipate its own heat, the heat emitted being dissipated in proportion to the difference of temperature which exists between the cable and the surrounding medium, and the conductivity of the latter. It would appear, therefore, that cables laid direct in the soil or in troughing will not carry such heavy currents as those drawn into conduits, providing the latter are efficiently ventilated, owing to the air conducting the heat away better than the soil. Few experiments, however, as far as the author is aware, have been made to ascertain the actual and safe temperatures of underground cables, and it is therefore difficult to form an opinion of the effect of heavy currents on cables with insulating and protective coverings of different kinds working under various conditions. One of the Board of Trade regulations states that the rise of temperature in a conductor shall not exceed 30deg. F., but probably few engineers know whether they conform with this regulation, and to what extent damage would ensue if the limit given is exceeded.

The author is of opinion that 1,000 amperes per square inch should be a perfectly safe current density, and for short periods cables should stand considerably more. The following axioms may be mentioned: larger current densities are permissible with small than with large cables, with single cables than with concentric cables, and generally with private lighting than with street-lighting cables, owing to the smaller amount of heat to be dissipated in the first and last cases and to the larger conducting surface in the second case. For ordinary working, a good current density on maximum load is about 700 or 800 amperes, but some engineers adopt 1,000 amperes per square inch as a standard. The current density allowed on ordinary maximum load should, however, be calculated in conjunction with the drop in pressure and the most economical current density, the latter being fully explained in an answer by the author to Question No. 753, appearing in the *Electrical Engineer* of Feb. 3, 1905.—H. A. N.

*Answer to No.* 777 (*awarded* 5*s.*).—The customary limit of density of current is 1,000 amperes per square inch in cables used for feeders and distribution, but although this limit is set by many fire offices, it is not altogether a good one for all sizes of cables. A maximum rise in temperature

Digitized by Google

for conductors is also set at 75deg. F. above atmosphere with double the normal maximum current—that is to say, with normal maximum working current a rise of 19deg. F. is permitted. Kennelly gives the rule

$$d = \frac{\sqrt[3]{C^2}}{68},$$

connecting the diameter of the cable with the current so that the above limit is observed. If the limit of 1,000 amperes per square inch were worked to, it is apparent that for large conductors—over ·2 square inch—a greater rise in temperature than the 19deg. would result, and at one square inch area the 1,000 amperes is 50 per cent. more than Kennelly's rule admits. Probably "E. B." will calculate out the permissible current from Kennelly's rule and may find that the 1,000 amperes per square inch is too high. Of course feeders, insulation, etc., have bearing on this question, but the rule given will cover most natural modern conditions. Often abnormal and unexpected effects are met with—for instance, with alternating current transmitted some 2,400 yards, six ·3 square inch feeders working in parallel at a current density of but 500 amperes per square inch allow of a drop of 90 volts. Further details of the conditions of the case "E. B." presents might throw more light on the reason for the excessive heating.—S. E. T.

*Question No.* 778.—A large institution requires a 14-h.p. motor for a laundry and also want the same motor to augment a deficient water pressure—due to high ground on which building is situated—in case of fire, by working a pump fed by the water supply. How can the motors be best arranged to fulfil this two-fold purpose?

*Answer to No.* 778 (*awarded* 10*s.*).—The requirements of the question seem to be that a 14-h.p. motor shall be used for driving the laundry machinery, and shall be so arranged that, in case of fire, the laundry load can be thrown off the motor and a pump coupled up. Well, now, it is obvious from the nature of the question that the change from machinery to pump must be a quick one, and the quicker it is the more valuable will the arrangement be.

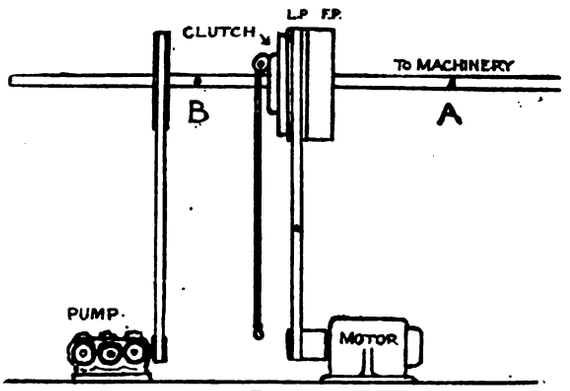

FIG. 1.

I should suggest the following method: In Fig. 1, L P and F P are the loose and fast pulleys respectively of the main shaft, A, driving the laundry machines. To the left of these pulleys is a short length of shaft, B, supported by

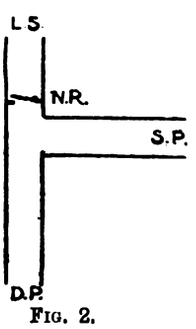

FIG. 2.

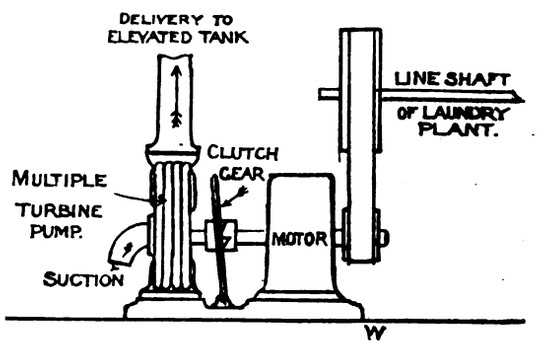
its own bearings, and quite separate from A, but in a direct line with it. A pulley friction clutch is fitted to the loose pulley and shaft B, so that they may be coupled together by means of turning a handle, H. The pump is driven by belt from a pulley on B. In case of fire the method of procedure would be as follows: Suppose the laundry is being driven, and belt, C, is on F P. By means of a belt shifter the belt is put on L P, and this disconnects the shaft A. The clutch is next tightened up, and this drives B and the pump. In stopping the motor, the clutch should be released before the current is cut off.

To facilitate quick change, a slight modification in the pipe connections for the water is advisable. In Fig. 2 let D P be the water supply for the institution. A branch, S P, is taken to the pump suction pipe, and L S is the ordinary water supply to the laundry. If a non-return valve, N R, be fitted in L S, then, as the pump is full of water, it may be started without the opening or closing of any valves, which, as a rule, take up a considerable amount of time.

To ensure readiness and effective working, the whole arrangement should be tried at least once a week, and the working parts of the friction clutch well inspected.—P. D.

*Answer to No.* 778 (*awarded* 7*s.* 6*d.*).—From the wording of the question it is understood that a 14-h.p. motor is to be installed for driving the line shafting in the laundry, and that the same motor is to be able to drive a pump which will augment the head of water sufficiently to deal with an outbreak of fire. The leading feature, then, about the pumping arrangement must be that it shall be absolutely reliable; it thus follows that it must be as simple as possible, and that there must be no parts liable to get out of order and require adjustment. Centrifugal pumps can now be obtained from the leading makers which are capable of pumping to any height desired, from a few feet, say 20ft., to 2,000ft. They are extremely simple, reliable, require no adjustment, and are low in first cost, and if the right sort of pump is selected they work at a good efficiency; they can also run at high speeds, and can thus be direct connected to a motor. The scheme suggested is shown by the accompanying rough sketch. The motor drives the laundry line shafting in the usual way and is mounted on a sole-plate, which also carries a multiple turbine high-lift pump and a simple form of clutch gear which allows the motor to drive the pump direct. The pump is fed by the water supply, and delivers into an elevated tank, which tank should be



about 30ft. above the highest point of the building it is wished to protect. Various points of vantage should be marked off, and each furnished with a water service from the tank, and the tank should be of such a size as to be able to hold a reserve of two hours' supply without calling upon the pump, and with all the fire service hoses in full play. The tank should, of course, be suitably housed, and each week the various jets should be tried, the water not needing to be wasted, as the top windows, etc., of the building can be swilled in this way; the tank should then be filled up again, and the time noted that it takes the pump to refill it—this will keep a check on the working of the pump. From the wording of the question it has been understood that there will be no chance of the pump losing its water as the water supply flows to it, and enables it to work just drowned; however, if this is not the case, a couple of pipes run from the top tank to the suction of the pump will do all the priming required. An installation on the above lines will afford adequate protection against fire, a full supply of water being available any time, thus allowing an outbreak to be tackled at once without any waiting.—W. T. W.

[Other replies to Question No. 778 will be given in our next issue.—ED. *E. E.*]

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

785. It is noticed that dust collects much more on the positive than on the negative 'bus bars in a central station, also that it collects on the glass panes opposite the bars, and that more collects opposite the positive bar than the negative. How is this explained?—H. G. H.

786. At a hydro-electric installation some surplus power is available. State the best method of obtaining a record of the same with a view to installing another turbine 12 months hence. Fall, 11ft., subject to frequent floods.—A. R.

### ANSWERS.

*Question No.* 778.—A large institution requires a 14-h.p. motor for a laundry and also want the same motor to augment a deficient water pressure—due to high ground on which building is situated—in case of fire, by working a pump fed by the water supply. How can the motors be best arranged to fulfil this two-fold purpose?

*Answer to No.* 778 (*awarded 7s. 6d.*).—The best arrangement for this two-fold purpose seems to me to be that the pump and motor be fixed on a bed-plate and coupled together by a jaw clutch when working together. This method keeps a very compact set, and, if anything, is cheapest.

The method of connecting the motor to the pump depends on the speed and type of pump used. The speed of a 14-h.p. motor is about 700 revolutions per minute, which is about the same speed as an 8in. centrifugal pump delivering 1,050 gallons per minute with a 20ft. lift and requiring 15 h.p., so we will assume that this pump be used. The arrangement shown in Fig. 1 may be applied satisfactorily,

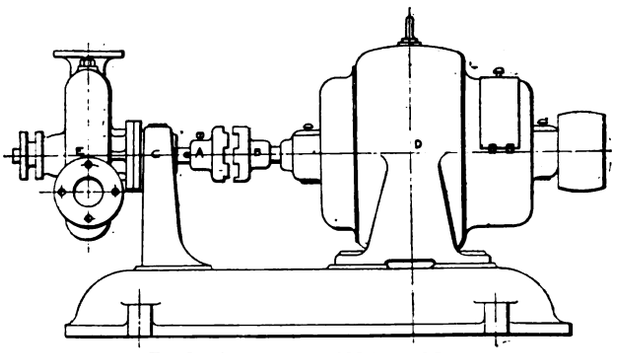

FIG. 1.—Arrangement of Motor and Pump.

the motor, D, being fixed to an extended bed-plate supplied with facings to carry the pump bearing, C. On the back end of the motor shaft is keyed one half of a jaw clutch, B, which engages the other half, A, which slides on a feather key let into the pump spindle. When the motor is driving the laundry shafting, the loose half of the clutch, A, is thrown out of gear along the shaft, and held so by a set pin. When it becomes necessary to use the pump, the motor must be stopped, the belt thrown off, and the loose half of the clutch put into gear and tightened by the set pin. All this may be done very quickly in case of fire. It will be noted that the pulley is keyed on to the commutator end of the motor shaft. Complete shifting gear in the shape of a lever may be applied for throwing the clutch in and out, but as a fire is a very rare occurrence this is unnecessary, and entails more expense.

A shunt-wound motor would suit the purpose best, and the direction of rotation must be chosen so that it suits both pump and shafting, and if this cannot be done effectively, a change-over switch should be placed between the motor and starter and connected as shown in Fig. 2.

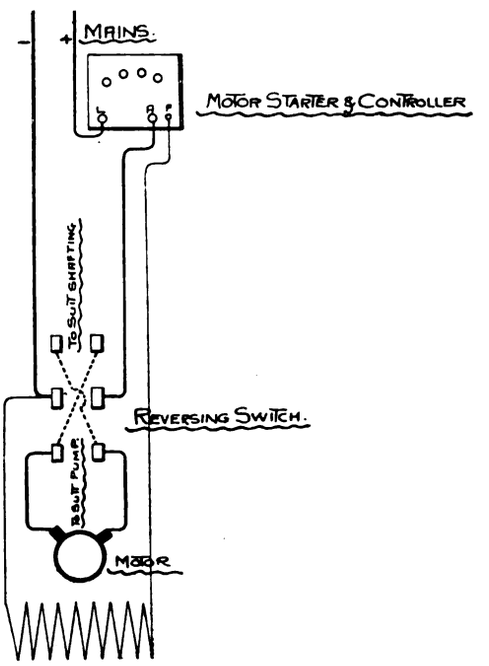

FIG. 2.—Diagram of Connections between Shunt-Wound Reversible Motor and Starter.

This may be used instead of a reversible controller, which, with its two sets of contacts, might "fog" the attendant as to which direction to turn when starting. If the motor connections are on the outside, the armature or shunt leads may be changed by hand almost as quickly to reverse the direction of rotation. With a shunt-wound motor either the armature leads or the shunt connections must be changed, and not both If the speed of the motor requires a little alteration to drive the pump at its most effective speed, a resistance may be placed in the armature or shunt circuit of the motor, to enable the speed to be either raised or lowered as required. If the speed needs decreasing, the motor starter may be wound as a controller at a little extra cost.

Should a double-acting slow-speed pump be used, it will require either a single or double reduction gear fixed between itself and the motor, and the wheel that gears into the motor pinion must be free to slide on a feather, in or out of mesh as required. If for any reason the pump cannot be coupled direct to the motor, it may be driven off a countershaft by belt, but I believe the best method is as described above, and as shown in sketch.—P. DEAN.

*Answer to No.* 778 (*awarded 7s. 6d.*).—The best arrangement would be to have an overhead tank fixed on the top of some building at a sufficient height to get pressure enough for the purpose and keep this tank full by means of a centrifugal pump driven by the laundry motor. With this arrangement a plentiful supply of water would be ready at any time of the day or night in case of fire. One important point would be that if the fire was not of very large dimensions, it would be immaterial whether the electrical supply were on or off. The laundry motor is shown in Fig. 1, and the method of driving indicated. The arrangement is very simple, and probably all the laundry machinery will be stopped and started in the same way. The only difference between the two cases is that in Fig. 1

Digitized by Google

the pulley *b*, instead of being loose, is keyed to a small countershaft which drives the pump. Under normal conditions the belt will be on pulley *a* driving the laundry machinery, but in case of fire the motor would be started up, the handle, *c*, pulled, causing belt to move on to pulley *b*, the stop valve, *e*, shown in Fig. 2, opened, allowing water from town mains to rush up into the pump and be delivered into tank. If the supply of electricity can

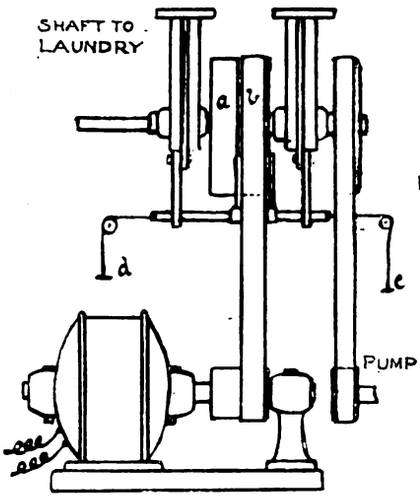

FIG. 1.

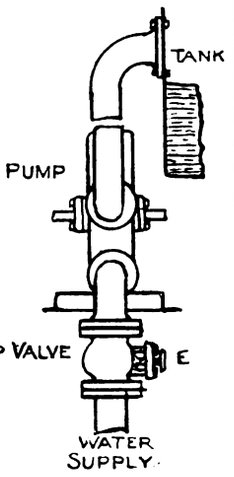

FIG. 2.

be absolutely relied on, then the expense of the overhead storage tank can be dispensed with. The same arrangements hold good with the exception of the pump delivering the water direct to the fire hose. Two centrifugal pumps may be connected in series if a high pressure is desired. This type of pump is very suitable for electrical driving, as it runs at a high speed, and thus saves a lot of expensive gearing. The laundry motor may be coupled direct

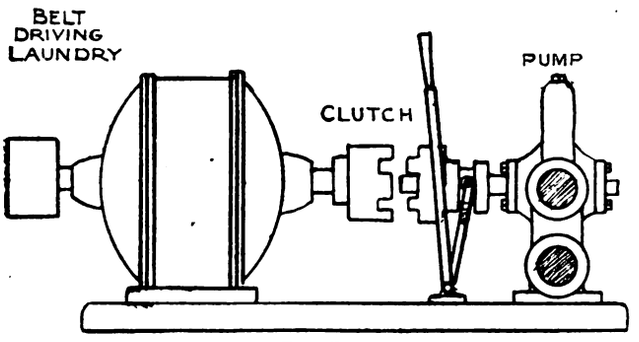

FIG. 3.

to the pump, if desired, through some simple form of clutch, as shown in Fig. 3. Both machines would be mounted on the same bed-plate, and the pump connected to the motor whilst it was standing, the belt being thrown off the laundry machinery countershaft if desired.—RESEARCH.

*Answer to No.* 778 (*awarded* 5*s.*).—"A. R." does not state very clearly what is exactly required. It is assumed that the motor will require to drive a line of shafting from which the various machines will be driven by fast and loose

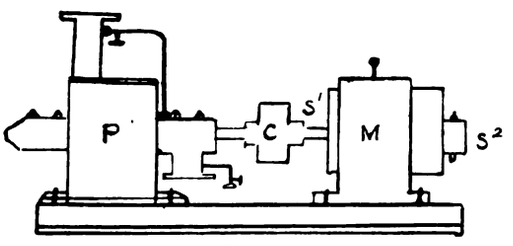

FIG. 1.

pulleys. The driving of the pump will depend upon the type chosen. Pumping may be done either by a direct-driven centrifugal pump or by ram pumps driven through gearing or belt. If a centrifugal pump is chosen, one sole-plate could be made suitable for motor and pump as shown on Fig. 1—P, pump; C, clutch; M, motor. It would be advisable to have some form of clutch in case of fire, which is easily engaged and disengaged while the shaft is in rotation. The act of engagement should be practically without shock, yet take up the motion quickly. A suitable armature spindle could be made so that pulley for line shafting could be put on either at $S^1$ or $S^2$. The belt would

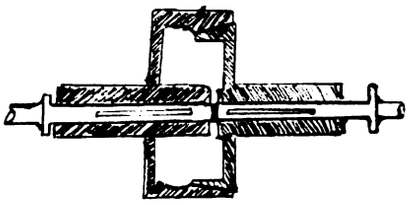

FIG. 2.

be off when driving pump. One type of friction clutch is shown on Fig. 2. Claw clutches are used when it is possible to stop for purpose of coupling. A belt-driven pump could be arranged as shown on Fig. 3, providing "A. R." has

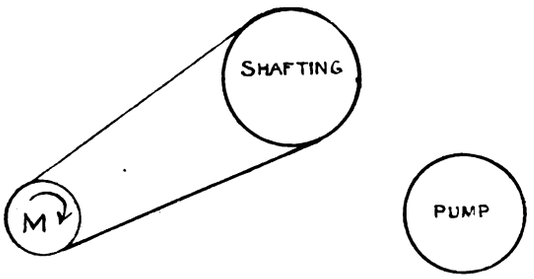

FIG. 3.

plenty of room, and could find suitable positions for motor and pump giving the right direction of rotation for pump and shafting. Fig. 3 shows belt driving line shafting and Fig. 4 driving pump. It is assumed "A. R." knows the

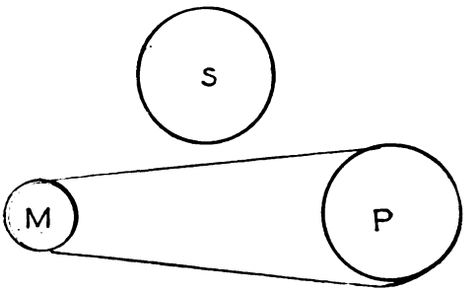

FIG. 4.

horse-power of pump which can be driven by a 14-h.p. motor.

$$\text{H.P. of pump} = \frac{\text{number of gallons} \times 10 \times \text{total head in feet}}{33{,}000}$$

Allow 20 to 40 per cent. for friction, bends, etc. The above is a formula which may prove useful to "A. R."—C. W. H.

*Question No.* 779.—A three-phase induction motor, with star-connected stator windings, is so arranged that each limb of the star consists of

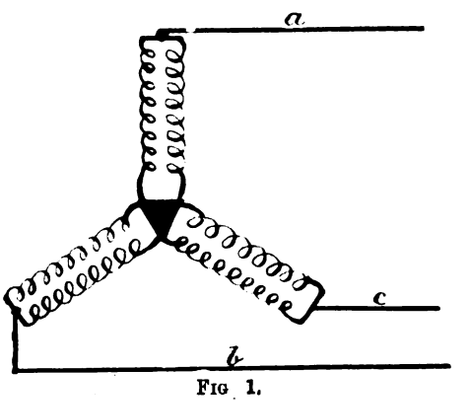

FIG. 1.

two parallel circuits, each circuit producing one set of poles and its neighbour the opposite set (see Fig. 1) If these circuits were

Digitized by Google

placed in series, still star connected (see Fig. 2), in what manner would the machine power factor and efficiency be affected at light and full loads?—MESH.

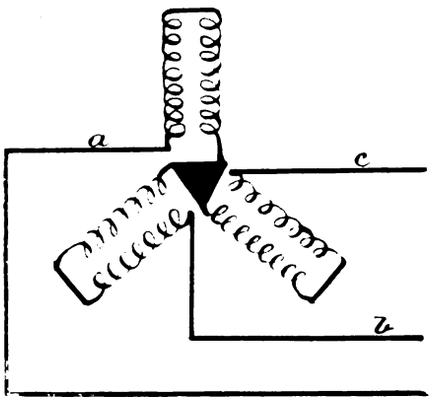

FIG. 2.

*Answer to No.* 779 (*awarded* 10*s.*).—The question does not state what voltage is to be used on the motor after reconnecting from Case I. to Case II, but it is presumed that twice the voltage used with the former is to be used with the latter connection. If the same voltage were used in both cases, it will be seen that by doubling the number of turns in series per phase we halve the flux per pole, and thus reduce the output of the motor approximately in the ratio of 4 to 1, and in all probability it would be unable to perform the duty required of it. Assuming, then, that the voltage is going to be doubled when the motor is running with all the poles in series per phase, we shall see that the power factor and efficiency will remain the same in the two cases.

Let the notation for the case when we have two poles in parallel per phase be as follows:

V = stator voltage per phase;
I = stator current per phase;
$x_f$ = stator reactance per phase;
$x_a$ = rotor reactance per phase ($x_a$ being here reduced to have that value it would have if there were the same number of phases in the rotor as in the stator and the same number of turns in series in each);
$C_m$ = magnetising current per phase in stator.

Taking first the power factor into consideration we have the well-known formula,

$$\cos\phi = \frac{1}{\sqrt{1 + (\%\, x_f\, I + \%\, x_a\, I + \%\, C_m)^2}}$$

where

$$\%\, x_f\, I = \frac{x_f\, I}{V};$$

$$\%\, x_a\, I = \frac{x_a\, I}{V};$$

$$\%\, C_m = \frac{C_m}{I}.$$

Now, the reactance per phase will vary with the square of the number of turns in series per phase, so that, as in the second case, we have twice the number of turns in series per phase that we have in the first case, the stator reactance will be altered to $2^2\, x_f\, I$, and the rotor reactance per phase will be $2^2\, x_a\, I$. The magnetising current in Case II. will be $C_m/2$, for to get the same flux per pole we shall require the same number of ampere-turns per pole as before, but now, since all the poles are in series instead of two in parallel, we shall only require half the former current from the line—*i.e*, $C_m/2$. Thus for the power factor in the second case we have, with line current I/2 and line voltage 2 V,

$$\cos\phi = \frac{1}{\sqrt{1 + \left(\frac{4\, x_f\, I}{4\, V} + \frac{4\, x_a\, I}{4\, V} + \frac{2\, C_m}{2\, I}\right)^2}}$$

$$= \frac{1}{\sqrt{1 + \left(\frac{x_f\, I}{V} + \frac{x_a\, I}{V} + \frac{C_m}{I}\right)^2}}$$

*i.e.*, it is the same as before, and since I is an arbitrary value of the current, this will hold for any value from no load to maximum output.

Looking now at the question of efficiency, with the same flux in the machine we will have the same core loss, also the friction will remain unchanged. For the same watt input we shall have half the current in Case II. that we have in Case I., since the power factor, as shown above, is the same in each case. The resistance in Case II. will, however, be four times what it is in Case I., since we have now twice the length and half the cross-section of copper per phase, so that although $I^2$ is, in the latter case, one quarter of what it is in the former, this increase of resistance just balances again the $I^2\, R$ losses in each. This, of course, applies to the rotor as well as to the stator, since, as stated before, we can always consider the rotor winding to be reduced to the same number of phases and the same number of turns in series per phase as in the stator. For the same watt input, then, we have the same losses in the two cases, and thus the same output, and, following on that, the same efficiency. As in the case of the power factor, this holds good for any value of the current in the motor.—MAC.

*Answer to No.* 779 (*awarded* 7*s.* 6*d.*).—The change contemplated amounts to doubling the effective stator turns in series per phase, and reducing the effective sectional area of the stator wire by half. In order to make the result of these changes clear, it will be necessary first to describe the action of an induction motor shortly. When such a motor is running unloaded, a small current, consisting partly of the wattless magnetising current producing the flux of the motor, and partly of a power current representing the no-load losses of the motor, flows into the stator. The value of the magnetising current depends on the dimensions of the magnetic circuits, the number of turns, etc., and adjusts itself automatically until sufficient stator flux to produce a back voltage in the stator windings nearly equal to the supply voltage is set up. The value of this flux is given by the expression

$$\text{Flux} = \frac{\text{internal stator volts per phase} \times 10^8}{\text{stator turns in series per phase} \times \text{periodicity} \times 4\,44}$$

The speed of the rotor at no load is slightly less than the synchronous speed—*i.e*, than the speed of rotation of the magnetic flux—so that the rotor conductors may cut the flux at a rate just sufficient to induce the small rotor current, which, in combination with the flux, produces the no-load torque, overcoming the friction, etc., of the motor.

When load is put on to the motor pulley, the rotor slows down slightly so that its conductors cut the flux at a greater rate—*i.e*, so as to produce a greater difference in speed or a greater "slip" between the rotor conductors and the rotating flux—so as to increase the rotor current and the torque. This torque is proportional to: rotor current × useful rotor flux. As the load and the current increase, however, the flux set up by the stator windings would very soon be reduced to zero by the opposing action of the rotor ampere-turns, and to avoid this the stator current automatically increases step by step with the rotor current, so as always to leave sufficient excess stator ampere-turns over rotor ampere-turns to produce the working flux. Now, in every motor some leakage of magnetic flux takes place between the stator where the flux is produced and the rotor where the flux is used. Such leakage, for instance, occurs across the slots, around the ends of the coils, and across the tops of the teeth, and it is practically proportional to the total ampere-turns. The amount of this leakage is usually defined as the difference between total stator flux at no load and useful rotor flux at no load stated as a percentage of the latter, and it usually lies between 5 and 10 per cent. The total stator flux being practically constant at all loads, the useful rotor flux has its maximum value at no load and diminishes gradually as the load increases, until when the stator current has reached a value which is approximately equal to as many times the no-load current as the total flux is times the no-load leakage flux, the whole of the flux is leakage, so that no useful rotor flux is left, no torque is exerted, and the motor caused to rest on short-circuit.

We can now consider the effect of the change of stator turns on (1) the losses and efficiency, (2) the power factor,

Digitized by Google

and (3) the speed of the motor at no load and full load. At no load the action of the motor will be improved all round, for the halving of the stator flux will reduce the necessary magnetising ampere-turns by half, and since the effective turns of the stator are doubled, the actual magnetising current will only reach one quarter its old value. The halving of the flux will further reduce the iron losses in the motor to about one-third of their old value. The friction losses will remain unchanged, whilst the $C^2R$ losses will be considerably reduced, but since these are in any case negligibly small at no load, they need not be considered. The power factor will be considerably improved, because whilst the losses as a whole have only fallen slightly, the wattless magnetising current (on which the no-load power factor chiefly depends) has fallen to one quarter of its old value. The speed of no load will be slightly less than before, but still practically indistinguishable from synchronous speed.

Turning next to the full-load conditions, the results will be found far less satisfactory. With the same input current the ampere-turns after the alteration will have double their old value because of the increased stator turns. This will mean practically double the actual leakage flux, and since the total flux is halved, the leakage, stated as a percentage of the total flux, will be four times as great as before. Now the rotor torque is approximately $\propto$ . Useful rotor flux $\times$ rotor current, and since the rotor current is doubled whilst, owing to the increased percentage leakage, the useful flux is considerably less than half its old value, the rotor torque and output will, for the same input, be considerably less than before the alterations. The iron loss will be reduced (as at no load) to about one-third of its old value. The friction losses will remain unchanged, whilst the $C^2R$ losses will be four times as great as before the alteration. This increase in $C^2R$ losses will usually far outweigh the fall in iron loss, and the increased losses together with the reduced useful output will greatly reduce the full-load efficiency after the alteration. The slip after alteration will be approximately four times as great as before, because besides the flux reduction there is an increase in rotor current to be produced. The power factor at full load will be considerably lower after the alteration, because it is proportional to $\frac{\text{rotor torque}}{\text{input current}}$, and, for the same input current, the rotor torque is considerably reduced.

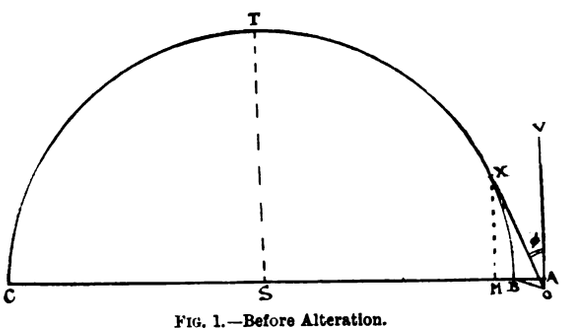

FIG. 1.—Before Alteration.

The approximate numerical effects of the alteration can be most simply arrived at by means of the Heyland diagrams shown in Figs. 1 and 2. Set off A B horizontally to represent the magnetising current to some scale. Continue A B to C, making B C equal to magnetising current $\times \frac{\text{total useful flux at no load}}{\text{leakage flux at no load}}$, or (which is practically the same thing) make B C equal to the stator current taken by the motor on short-circuit. On B C draw a semicircle. From A draw A O equal to the no-load power current, and at right angles to A B. Then O B is the no-load current, and lines like O X drawn from O to the semicircle represent stator input currents to the same scale as that to which A B represents the magnetising current. The full load of a normally-designed motor would occur approximately at the line O X. Vertical heights like X M are proportional to the torque corresponding to the current O X. The cosine of the angle V O X is the power factor at the current O X. The proportions of Fig. 1 apply to the motor before alteration, and are drawn on the assumptions that (1) the magnetising current, A B = 25 per cent. of the full-load current, O X; (2) the leakage at no load is 6 per cent. of the useful flux at no load—*i.e.*, B C = A B $\times \frac{100}{6}$; (3) the no-load loss current, A O, is 5 per cent. of the full-load current, O X, 3 per cent. being taken as iron loss and 2 per cent. as friction.

Fig. 2 represents the diagram for the same motor after the alteration, and is drawn to the same scale as Fig. 1.

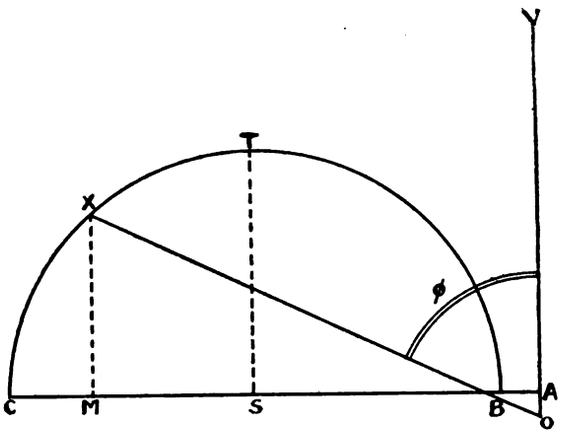

FIG. 2.—After Alteration.

O X is the same length, and represents the same current in both diagrams. A B in Fig. 2 is $6\frac{1}{2}$ per cent. of O X. B C is equal to A B $\times \frac{100}{6}$ (*i.e.*, B C in Fig. 2 is one-fourth the length of B C in Fig. 1). By scaling off the diagrams the following approximate results are obtained:

*At No Load.*—Power factor before alteration (= cos A O B in Fig. 1) = ·19.

Power factor after alteration (= cos A O B in Fig. 2) = ·48.

No-load losses before alteration = 5 per cent.

" " after " = about 3 per cent.

*At Full Load* (*i.e.*, at the same input current O X before and after alteration):

Power factor before alteration (= cos V O X, Fig. 1) = ·92.

Power factor after alteration (= cos V O X, Fig. 2) = ·44.

$$\text{Efficiency before alteration} = \frac{92\% - (3\% + 2\% + 5\%)}{92\%} = 89\%.$$

$$\text{Efficiency after alteration} = \frac{44\% - (1\% + 2\% + 20\%)}{44\%} = 48\%.$$

$$\text{Ratio of torque before alteration to torque after alteration at the same input} = \frac{\text{X M in Fig. 1}}{\text{X M in Fig. 2}} = 2{\cdot}1.$$

Since the speed after alteration is somewhat less than before, the ratio of brake horse-power in the two cases will be even less favourable to the altered motor. Ratio of maximum possible torque before alteration to the same after alteration $= \frac{\text{T S in Fig. 1}}{\text{T S in Fig. 2}} = 4.$

It will be seen that whilst the motor is improved at no load or very light loads, it is greatly altered for the worse at full load—in fact, with the data assumed (and these are not particularly unfavourable), the motor would be quite unable to give its full-load output after the alteration, even supposing it to be worked at the maximum output, T S in Fig. 2. The alteration would, therefore, be quite out of the question, except as a temporary expedient for improving the no-load working conditions.—Q.

[Other replies to Question No. 779 will be given in our next issue.—ED. *E. E.*]

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within 10 days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS.

787. Has Reuleaux's diagram been adapted to the analysis of the Corliss valve motion? If it has, explain the method and show how by its use problems relating to a double eccentric gear may be solved.—G. H. H.

788. A three-phase 3-h.p. induction motor with squirrel-cage rotor takes 20 amperes at starting on no load. When the speed has got up to normal the current is two amperes. With the idea of decreasing starting current, a choker is connected in circuit. This choker consists of three separate superimposed windings, one in each phase. On again starting motor, the initial current is now 14 amperes, and running current scarcely readable. What is the reason for this apparent increase of power factor?—P. D.

### ANSWERS.

*Question No.* 779.—A three-phase induction motor, with star-connected stator windings, is so arranged that each limb of the star consists of

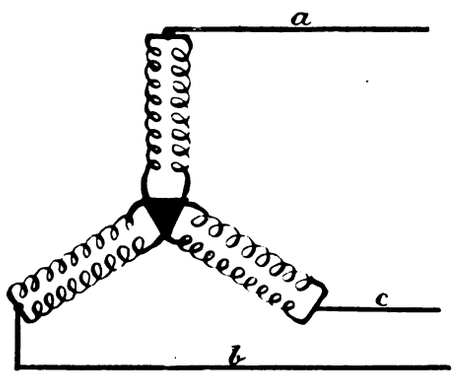

FIG 1.

two parallel circuits, each circuit producing one set of poles and its neighbour the opposite set (see Fig. 1) If these circuits were placed in series, still star connected (see Fig. 2), in what manner

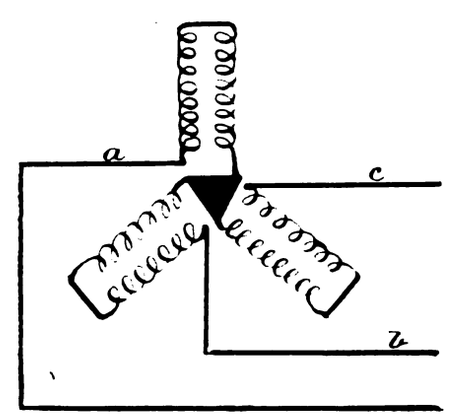

FIG. 2.

would the machine power factor and efficiency be affected at light and full loads?—MESH.

*Answer to No.* 779 (*awarded* 7*s.* 6*d.*).—The connections shown in the second figure given with the question would change the motor into one with half the number of poles. If the first winding gave + − + − + − + −, the second would give + − − + + − − +, as the current would be reversed in half the stator windings. Since the impedance is doubled the voltage applied must be doubled, and then the current in each stator conductor will be the same as before. Since the number of poles is half, the speed will be twice as great and the torque half. This means less slip, and therefore greater efficiency at full load. As the rotor will be too big for its new speed, the no-load current in each conductor may be somewhat larger. Since the poles are now of greater pitch there will be less dispersion, and the power factor will be improved. The iron loss will not be altered, as the densities and the number of the reversals are as before. The copper loss in the stator will be practically the same, but that in the rotor will be one-fourth of its previous value, as the current needed for the torque is halved. If the current be sent round the stator to produce the same fields as before, the resistances and reactances are simply put in series. The voltage must be doubled to get the same current in each stator conductor. The flux, dispersion, copper and iron losses, and slip remain exactly as before.—E. S.

*Answer to No.* 779 (*awarded* 7*s.* 6*d.*).—The question which is raised above is a most important one, because it is one which, in one form or another, has always, without *exception*, to be carefully considered in the correct design of polyphase and single-phase induction motors, comprehending, as it does, the influence of the pure ohmic resistance of the windings of the stator of the motor upon the working of the motor and all the quantities, such as torque, slip, power factor, etc., which are connected therewith. Perhaps the simplest and, at the same time, the clearest way of determining the manner in which the alteration of the internal connections of these windings affects the power factor and the efficiency of the motor at light load—or no load—and full load is through the medium of that comprehensive diagram known as Heyland's diagram. The writer has, however, no intention of treating of the theory and construction of this diagram as a whole, but will assume its correctness, and merely deal with so much of it as is required by the demands of the above question. As a prelude to dealing with the diagram proper, it is obvious that if $r$ is the pure ohmic resistance of the winding of each limb of the star, then $2r$ is the resistance of each of the parallel circuits composing each limb. When, however, the internal connections have been so altered that the second figure of the question represents the new conditions, then the two circuits are in series one with the other, and the resistance now of each limb of the star is double that of either of the separate circuits—namely, $4r$—or four times the original resistance of the limb.

Turning now to the application of the Heyland diagram to the case in question, we shall first consider whether the power factor of the motor is affected by the aforementioned change or not, and, if it is, in what peculiar way. In Fig. 1 we have a portion of the ordinary form of the diagram, and in it O A represents the stator flux; O C represents the light-load current, O C, represents the full-load current; O E represents the E.M.F. induced in the primary or stator conductors, which E.M.F. is of the nature of a back pressure; E $e_p$ represents the drop in pressure in the stator windings, at the light load, due to the pure ohmic resistance of $r$ ohms; E $e_p'$ represents the corresponding drop at full load; E $e_p''$ represents the drop in pressure, at light load, due to the pure ohmic resistance of $4r$ ohms; E $e_p'''$ represents the corresponding drop at full load; O $e_p$ represents the impressed E.M.F. for the first arrangement of windings at light load; O $e_p'$ represents the corresponding E.M.F. at full load; O $e_p''$ represents the impressed E.M.F. for the second arrangement at light load; and O $e_p'''$ represents the corresponding E.M.F. at full load.

*First Arrangement—Light Load.*—Referring to Fig. 1, it is evident that the current lags behind the impressed

Digitized by Google

pressure, O $e_p$, and that the phase relationship of the pressure to the current is the angle C O $e_p$. Therefore, the angle C O $e_p$ is the angle of lag of the current supplied to the motor for this load, and the cosine of this angle is the power factor of this motor.

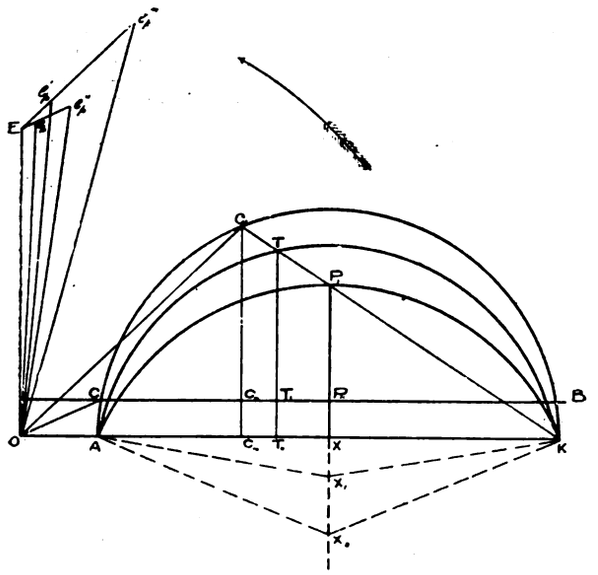

FIG. 1.

*Second Arrangement—Light Load.*—In this case it will be observed that the position and direction of the vector representing the impressed pressure have been changed; this is the direct result of altering the resistance of the stator windings. Also the change has been such that the magnitude of the angle of lag—which is now the angle C O $e_p''$ instead of C O $e_p$—has been diminished. But as the cosine of any angle within the limits of 0deg. and 90deg. increases as the angle decreases, it follows that the cosine of the new angle is greater than that of the old angle. Hence, in this case, the power factor has been *increased.*

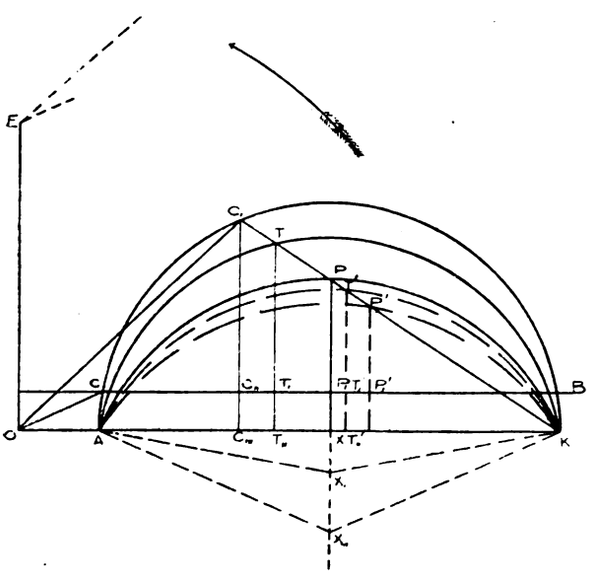

FIG. 2.

*First Arrangement—Full Load.*—Following the lines of reasoning as above, we see that the angle C, O $e_p'$ is the phase relationship between the pressure and the current, and that the cosine of this angle is the power factor of the motor for full load.

*Second Arrangement—Full Load.*—As in the above case, the position and direction of the vector representing the impressed pressure across the terminals of the machine have been changed, with the result that the angle C, O $e_p'''$ is less than the angle C, O $e_p'$; or, in other words, the angle of lag of the current has been made smaller. Hence the cosine of the angle of lag has been made larger, and, as a consequence, the power factor of the machine has been *increased.*

Therefore, in both cases of light load and full load, the change proposed in the question would lead to an increased power factor.

Considering, now, the effect produced on the efficiency of the motor, we have in Fig. 2 another portion of the Heyland diagram. It is clear that at light load there cannot possibly be any efficiency, for the very simple reason that no external work is done; that is, what energy is absorbed by the motor is utilised in making up for such losses as core losses, heating losses, frictional losses, etc. At full load, however, the conditions are different, and, since there is external work done, there will be an efficiency. Referring to Fig. 2, if there were no losses in the motor of any kind, then C, C,,, to a certain scale would represent both the input and the output watts. To take into account, however, the internal stator heating loss, C, T is made, to a certain scale, representative of such, and to include the effect of slip, $\frac{P\,T}{T\,K}$ equals the percentage slip. Then the output watts are equal, to a certain scale, to P P,. The efficiency of the motor equals $\frac{P\,P_,}{C,\,C_{,,,}}$.

In the second arrangement the resistance of the winding is increased four-fold, and, consequently, the loss will be four times as great as it was before. This second loss is represented by C, T', and the slip by T' P'. The new output power is represented by P' P,', which, evidently, is smaller than P P,. Hence the *new* efficiency, which is $\frac{P'\,P_,'}{C,\,C_{,,,}}$, is *smaller* than the *old* one. This shows in a clear manner the effect of the proposed change.—G. W. B.

*Answer to No.* 779 (*awarded* 5*s.*).—

Let $r$ = the stator resistance;
$E_0$ = the supply voltage;
J = the current taken per phase;
$\phi$ = the angle of lag of J with respect to E.

In the first place, I wish to show the effect of the stator resistance on the power factor and efficiency of the motor, and then the effect of increasing the resistance, as it is obvious that the operation described in the question increases the stator resistance four times.

Now, owing to the resistance of the stator, there will be a small voltage drop, $e$, due to this cause. Its value will be $e = J\,r$. This drop will, of course, be in phase with the current, J. The voltage, E, used for power purposes in the motor will be the supply voltage reduced vectorially by $e$. In all calculations on the induction motor E is used, and a correction made afterwards as in Fig. 1. Now, of

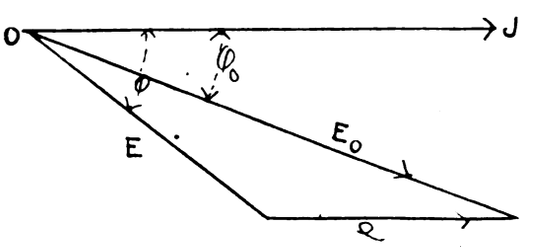

FIG. 1.

course, $e$ is very small compared with $E_0$ (but, of course, not small enough to be neglected). We get, therefore, the very approximate relation

$$E = E_0 - J\,r\cos\phi \quad . \quad . \quad . \quad . \quad . \quad (1)$$

This will easily be seen by referring to Figs. 1 and 2. I now wish to obtain in absolute terms the increase of power factor due to stator resistance

$$\cos\phi_0 = \frac{O\,N}{O\,Q} = \frac{O\,N}{E_0}$$

$$O\,M = E\cos\phi \text{ and } M\,N = e$$

$$\therefore \cos\phi_0 = \frac{O\,M + M\,N}{E_0} = \frac{e + E\cos\phi}{E_0}.$$

Substitute for $E_0$ the value obtained in equation (1), and we get

$$\cos\phi_0 = \frac{e + E\cos\phi}{E + e\cos\phi}$$

Digitized by Google

$$\therefore E\cos\phi_0 + e\cos\phi_0\cos\phi = e + E\cos\phi.$$

Now, $\cos\phi\cos\phi_0$ is very approximately equal to $\cos^2\phi$. Since $\phi - \phi_0$ is very small, indeed, and $\cos^2\phi = 1 - \sin^2\phi$.

$$\therefore E\cos\phi_0 + e(1-\sin^2\phi) = e + E\cos\phi.$$

$$\therefore \cos\phi_0 = \cos\phi + \frac{J\,r}{E}\sin^2\phi \quad . \quad . \quad . \quad (2)$$

This gives us in absolute terms the increase in power factor at any load due to the stator resistance. These two equations (1) and (2) are the ones given by Dr. Behn-Eschenberg in his paper on induction motors read before the Institution of Electrical Engineers, Jan. 14, 1904, p. 272. We have now to apply this equation (2) to the

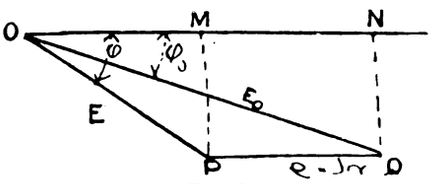

FIG. 2.

motor in question. Let its original resistance per phase be R. Then, on putting the stator coils in series as described, this becomes 4 R, and we get the two equations:

$$\left.\begin{aligned} \therefore \cos\phi'_0 &= \cos\phi + \frac{J\,R}{E}\sin^2\phi' \\ \text{and} \qquad \cos\phi''_0 &= \cos\phi + \frac{4\,J\,R}{E}\sin^2\phi'' \end{aligned}\right\}$$

$$\therefore \cos\phi''_0 - \cos\phi'_0 = \frac{3\,.\,J\,R}{E}\sin^2\phi''.$$

$\sin^2\phi''$ is very approximately equal to $\sin^2\phi'_0$. Therefore we obtain the result that by increasing the resistance of the stator coils as described we increase the power factor by an amount $\frac{3\,J\,R}{E}\sin^2\phi'$. The power factor of the motor can easily be obtained from the Heyland diagram, and I do not think it necessary to describe this here, as it is so well known. We have now to consider the effect on the efficiency of the motor.

Let W = the no-load losses;
„ S = the slip per revolution.
The copper losses = $3\,J^2\,R$.
The efficiency, $n$, of the motor is given by

$$n = \frac{3\,J\,E\cos\phi\,(1-S)}{3\,J\,E\cos\phi + W + 3\,J^2\,r}.$$

As is well known, $S \propto \frac{1}{E}$

We shall therefore have to correct S by multiplying by

$$\frac{E + J\,r\sin^2\phi}{E}.$$

W is a constant. $\cos\phi$ I have shown will have to be increased as described, also E. We shall, of course, have to substitute for $r$ the value for our motor—*i.e.*, $R\,\phi + R$—and the difference will give the change in efficiency. The change of efficiency can be roughly calculated as follows: estimate the stator and rotor copper losses based on their resistance, and also the iron and friction losses, which Dr. Behn-Eschenberg gives as about five watts per kilogramme of iron, and then if A is the total output of the motor, B is the stator copper loss, C is the rotor copper loss, and D is the iron and friction losses. We get efficiency at full load

$$= \frac{A}{A+B+C+D}$$

and with B increased to 4 B we get the efficiency

$$= \frac{A}{A+4\,B+C+D}$$

and the loss of efficiency at full load is given by the difference

$$= \frac{3\,A}{(A+B+C+D)(A+4\,B+C+D)}.$$

I think that from the above note it will be possible to estimate the changes in efficiency and power factor, but, of course, a knowledge of the motor short-circuit characteristics and no-load characteristics will have to be known.—ERNEST P. HOLLIS.

*Answer to No.* 779 (*awarded* 5*s.*).—The suggested alteration in the stator coils mentioned introduces twice the original resistance into the circuit; this change would probably be productive of the following results, in describing which, for the sake of brevity, I will refer to the parallel arrangement as Case I. and the other as Case II. It is also here assumed that the induction motor is fitted with a squirrel-cage rotor and started up by means of a compensator or auto-transformer.

Considering, first, the condition of things on starting up the machine with either arrangement of windings, the same torque is necessary to overcome the inertia of the rotor and run it up to speed. With a doubled resistance only half the former current would flow in the stator coils, at the instant of closing the switch, thus only half the former torque would be exerted; consequently the rotor will not revolve and run up to speed so quickly, more slip being necessary to provide the turning effort. In Case I. the speed at no load will always be nearer synchronism than in Case II., due to the additional slip required to compensate for the higher ohmic resistance in the stator coils; it being here remembered that as the frequency of the currents in the rotor depends upon the slip, hence the torque increases—within limits—as the rotor speed lags behind that of the stator flux. The direct result due to the greater slip will be larger currents circulating in the rotor conductors, which will have the same effect as strengthening the fields of a synchronous machine—namely, an improved power factor. With an increasing load up to the economical carrying capacity of the windings in Case II., the power factor would still be higher than in Case I Reference has already been made to a certain limit, upon attaining which any addition to the rotor slip does not increase the torque. This limit is reached when the currents in the rotor circuit lag behind the E.M.F. producing them by 45deg, or when the E.M.F. necessary to overcome self-induction equals the E.M.F. required to overcome ohmic resistance alone. Therefore, in Case II., this limit of maximum torque is reached before Case I., and in the latter the power factor continues improving beyond the limit of Case II. Thus, with the improving power factor, the bigger load does not require a corresponding increase of current in the stator coils. In all probability a machine wound as in Case I. will not attain the limit of maximum torque until it is transmitting nearly double the energy of a similar motor wound as in Case II.

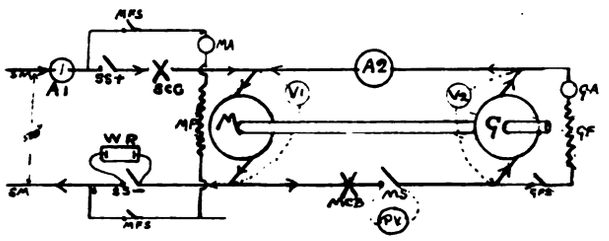
It would appear from the foregoing results that each type of winding had certain merits. In Case II., though the starting torque is low, on a varying load up to its limit of maximum torque, its efficiency would be greater than the other, owing to the power factor being better and the losses resulting from wattless currents being less. In Case I., the limit of maximum torque being reached later than in Case II, if the machine is subject to overloads, a higher efficiency ensues. From this it will be seen that induction motors wound with two parallel circuits, as in Case I., are well suited for starting up fully loaded, necessitating a large starting torque, and for running on full load with repeated heavy overloads of, perhaps, 100 per cent. Machines arranged as in Case II., to deal with heavy overloads, would require a greater area of copper in the windings—in fact, the motor would have to be of larger construction throughout. It is, however, specially, adapted for a varying load fluctuating between zero and its limit of maximum torque.

To put the whole subject briefly, the effect of increasing the resistance of the stator coils is to reduce the rotor flux, and with it also the torque; therefore, any reduction of the ohmic resistance in the stator coils will enable a machine to increase its torque, and, therefore, its mechanical efficiency, though at the cost of a diminished power factor on light loads.—WALLSEND ON TYNE.

*Question No.* 780.—How would you arrange the Hopkinson test and determine the efficiency on two 900 kilovolt-ampere 500-volt compound generators or machines?

Digitized by Google

*Best Answer to No.* 780 (*awarded* 10*s*).—The two generators are presumably directly coupled together, probably with the addition of a third bearing between the two armatures; also a supply of current at 500 volts is available. The question does not state whether the machines are compounded for constant or an increased voltage. However, to simplify matters, the series winding had better be cut out on both machines for the first test. Afterwards the series turns on the generator may be used either separately excited by a booster or self-excited and regulated by a shunt rheostat; this latter arrangement requires some skilful manipulation. Connect up as shown in the diagram. M and G are the motor and generator



M, Motor; MF, Motor Field; G, Generator; GF, Generator Field; SM, Supply Mains; SS, Single-Pole Switch in each Main; SCB, Circuit Breaker in Series with Positive Supply Main; WR, Water Rheostat across Negative Supply Switch; MS, Main Switch for Paralleling; MCB, Circuit Breaker in Series with Main Switch; MFS, Motor Field Switch; GFS, Generator Field Switch; A1, External Supply Ammeter; A2, Main Ammeter reading Circulating Current; MA, Motor Field Ammeter; GA, Generator Field Ammeter; V1, Motor Voltmeter; V2, Generator Voltmeter; PV, Paralleling Voltmeter.

armatures, the field of the generator self-excited. The brush leads on one side of each of the armatures are connected together through an ammeter shunt. The brush leads on the other side are connected together through a main switch and circuit breaker. It is advisable to use a circuit breaker here, as this gives the machines greater protection. The circuit breaker is also convenient to throw the whole load off the generator suddenly, a test frequently specified. The external supply circuit is brought through two single-pole switches with a circuit breaker on the positive side and a water rheostat across the negative switch for starting. A tachometer should be put on the shaft to facilitate speed regulation. The instruments should all be together on one board if possible, so that they can be seen at a glance. The main ammeter must be within sight of the operator while his hand is on the field rheostats; the tachometer and field ammeters should be also within sight.

To start up, close the field circuit of the motor and increase the field to its maximum value. Set the supply circuit breaker to about half full-load current—it may take more than this to start the first time—close the positive supply switch, dip in the water rheostat plates, and if the direction of rotation is right bring them together slowly, watching the supply ammeter meanwhile; when shorted, close the negative supply switch and take plates out. The direction of rotation should be made right for the machine—that is, to run as a generator. Then weaken the motor field, bring the combination up to speed, and calibrate the tachometer. Close the generator field circuit and main circuit breaker, and allow the machine to excite; adjust the voltage and parallel in the ordinary way with the main switch. Before paralleling, try the volts across the main switch, and see that this is zero or two or three volts in favour of the generator. It is wise to try this with a few volts on the generator, as then there is less risk of burning out the paralleling voltmeter in case the polarity of the generator is wrong. If the polarity of the generator is wrong, reverse the brush leads. Then adjust the motor field to give correct speed, and at the same time increase the generator field so as to get full-load current circulating between generator and motor. If the generators are good machines, the motor will easily carry the extra load, about 10 per cent. While on full load adjust the brush position. A very slight backward lead on the motor is generally sufficient; more lead than necessary on either machine, of course, reduces the efficiency. The direction of the current is shown by the arrows.

Before taking efficiency readings it is as well to run for some time to ensure the bearing friction being fairly constant, or, better still, take the efficiency readings after a temperature test. Then, keeping the speed constant, take readings of all instruments at regular intervals from no load to about 30 per cent. overload—about 10 readings in all. The brush lead should not be altered from full-load position. The approximate efficiency is given by

$$\sqrt{\frac{\text{output of generator}}{\text{input of motor}}} = \sqrt{\frac{A_2 \times V_2}{(A_1 + A_2) \times V_1}}.$$

This takes into account the losses in the field rheostats and friction in three bearings, which latter is not quite fair; it will probably make a difference of ½ per cent. to each machine. The hot resistance of the generator series field should be taken, and the $C^2R$ losses allowed for at the various loads.

To obtain readings with the generator series winding in circuit: Start up and parallel with this series winding shunted with a large water rheostat; the plates of the rheostat being shorted. Then, to bring up the load, gradually separate the rheostat plates, and at the same time weaken the shunt field until the full main current is passing through the series turns—or the series turns and the permanent shunt to them supplied with the machine. If paralleling is tried with the series in circuit and not shunted, the generator will build up the load before it can be controlled and open the main circuit breaker.

The above Hopkinson method is the one usually applied, but another one may be used provided there is at hand a booster capable of supplying full-load current and about 40 volts, and a supply of current at 500 volts for exciting the fields. The above method is very convenient for a temperature test, but, to obtain the efficiency with greater accuracy, the following may be followed to separate the losses: Run the combination at the correct speed, the generator not excited; read carefully watts supplied to the motor armature—probably a lower reading ammeter will be needed to read the supply current. This reading gives the watts lost in friction in two machines and the iron losses in one—call this A. Now separately excite the generator to full voltage, and, keeping the motor speed and field current absolutely constant, the speed may be regulated with a rheostat in the motor armature circuit. Do not include it in the voltmeter reading. Read the motor watts again. This gives the friction and iron losses in two machines—call this B. Then B – A = iron loss in the generator (call this C), and A – C gives the total friction loss, approximate enough for ordinary purposes. The friction loss may be halved between the two machines. Then repeat with the motor as generator. The $C^2R$ loss in each armature, in the series, in the shunt, and in the brushes can all be calculated for any temperature after the resistances have once been measured. For further separation of the friction losses take readings of the motor watts, the generator brushes lifted, and also with the generator armature out. From this last the friction of one bearing can be found.

To use the booster method mentioned above, connect all three armatures in series, the fields being excited off 500-volt supply. In this arrangement the armatures are connected to revolve in opposite directions, the motor field being increased until the torque is sufficient to turn the generator round. This method overloads the motor field instead of the motor armature, and is a little awkward to start up.—TESTER.

[Other replies to Question No. 780 will be given in our next issue.—ED. *E. E.*]

## QUESTIONS AND ANSWERS—CORRECTION.

SIR,—May I point out, in reference to my answer to Question 779 in your last issue, that the scale of Fig. 2 as printed is four times that of Fig. 1, instead of being equal to it, as stated.

Also that in calculating the efficiency the full load $C^2R$ losses before alteration have been taken as 5 per cent. of the input.—Yours, etc., Q.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

### QUESTIONS.

789. How may extra high electric pressures be measured by a low-reading electrostatic voltmeter and two condensers? Express the multiplying power of the arrangement in terms of the capacities, and state the conditions necessary for its constancy.—J. A. V.

790. Make a sketch and describe a mains-charging device suitable for a 1,000-kw. three-core power cable working at 10,000 volts. Explain fully why this apparatus is used on high-pressure alternating circuits.

### ANSWERS.

*Question No.* 780.—How would you arrange the Hopkinson test and determine the efficiency on two 900-kilovolt-ampere 500-volt compound generators or machines?

*Answer to No.* 780 (*awarded 7s. 6d.*).—For machines of such a large size, it would usually be more convenient to carry out the "parallel" rather than the "series" Hopkinson test, as the latter necessitates the provision of a low-volt dynamo or battery of about one-tenth of the capacity of one of the main generators, and capable of carrying the full current of the generator—*i.e.*, in this case, 1,800 amperes—and a dynamo for such an output as 50 to 100 volts by 1,800 amperes is rather an unusual one. The "parallel" Hopkinson test only requires a source of supply (dynamo or battery) of the same voltage as the generators (500) and capable of delivering a current of 10 to 20 per cent. of that of one generator. The connections for this test are shown

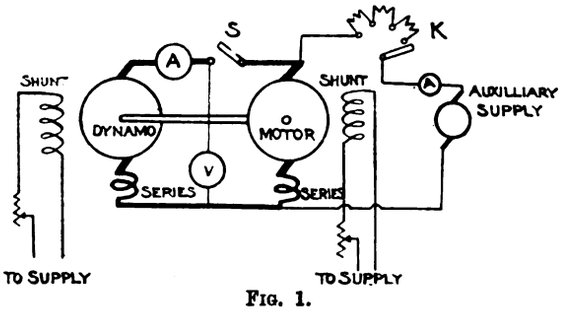

FIG. 1.

in Fig. 1. The shunt winding of both machines should, preferably, be separately excited, whilst the series windings can be self-excited in the ordinary way, although the test will be more perfectly under control if the series windings are left out altogether, provided that the whole excitation can be safely supplied by the shunt windings. If the series windings are used, care should be taken that the motor machine series winding is reversed relatively to the armature, so that it helps the shunt winding instead of opposing it.

To start the test, the two main generators are directly coupled together mechanically, and the main switch, S, between them is left open. The shunt of the machine which is to act as the motor is then excited, and the set is started up as an ordinary motor by switching on the auxiliary supply through the starting resistance, K. The shunt of the machine which is to act as generator is then excited until that machine gives the same volts as the auxiliary supply volts. Then switch, S, is closed and by slightly strengthening the shunt of the generator machine, or weakening the shunt of the motor machine, the current passing between the two main machines can be adjusted to the full-load current or any other value at which the efficiency is to be measured. It is best to weaken the motor field slightly and strengthen the generator field slightly, so that the average strength of field may be the normal value.

As the current flowing between the main machine increases, the current taken from the auxiliary source will also increase to correspond with the increased losses. The current in the motor machine is equal to the sum of the current in the dynamo machine and the auxiliary current. The output of the dynamo machine is, of course, terminal volts × dynamo amperes, whilst the output of the motor machine is (terminal volts × motor amperes) – (losses in motor), and this is equal to terminal volts × (dynamo amperes + half auxiliary amperes), for half the auxiliary amperes multiplied by the terminal volts are equal to the losses in one main machine. The *average output* of the two main machines is, therefore:

$$\text{Terminal volts} \times \left(\text{dynamo amperes} + \frac{\text{auxiliary amperes}}{4}\right)$$

and the commercial efficiency of one main generator at this average output, W, is given by the expression:

$$\frac{W}{W + \left(\frac{\text{terminal volts} \times \text{auxiliary amperes}}{2}\right) + \left(\begin{array}{c}\text{average of the } C^2R \\ \text{losses in the two shunt} \\ \text{windings.}\end{array}\right)}$$

Care should be taken that the leads between the main machines are short and of heavy section, as any loss in them appears as additional armature $C^2R$ loss in the efficiency calculation.—Q.

*Answer to No.* 780 (*awarded 7s. 6d.*).—I take it that the machines in the question are direct-current, although the phrase "kilovolt-amperes" is generally used in connection with alternating-current machines. The Hopkinson test is used to find the losses and efficiency of one of two similar machines. They must be exactly alike, both electrically and mechanically. These two machines are connected together by means of a flexible coupling. One of these machines is going to be driven as a dynamo and is going to drive the second machine as a motor. Obviously, we shall need an auxiliary source of power to supply the losses.

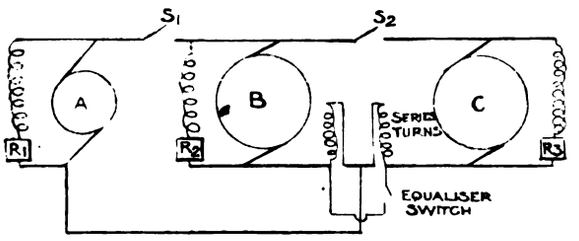

FIG. 1.

In Fig. 1 A is the auxiliary dynamo, which is, of course, one which will generate a pressure equal to the rated pressure of the generator to be tested. A is shunt-wound. I may state here that a battery could take the place of A if one is available. B and C are the two similar generators mechanically coupled together. I will suppose we are to test B. B will be run as a generator, and will motor C. As these generators, B and C, are compound wound, it is obvious that we must have an equalising connection, as is usual with compound-wound machines for well known reasons. This connection is made through an equalising switch shown in the diagram. Now, as the machines are compound-wound and self-excited, it follows that in C the series turns oppose the shunt, giving a differential winding, and, therefore, when we attempt to start the machine up, we shall probably reverse C. This can be got over either by separately exciting the shunt fields of C, and thus getting a strong shunt field to start with, or to reverse the series connections. I should advise the former method. It is often the practice to run each machine separately excited. $R_1$, $R_2$, and $R_3$ are rheostats in the shunt field, $S_1$ and $S_2$ are the main switches on each machine. The procedure of starting the machines is as follows: If the machines are to be separately excited, make

Digitized by Google

the fields first. Put in the equaliser switch, then $S_2$. Weaken the field of B, which is going to act as generator. If the machines are self-excited, just put in the above switches, and put nearly all the resistance in $R_2$. Start up the auxiliary dynamo, A, having it connected in such a way that its voltage assists the voltage of B and C. Adjust R until the voltage of A is about 100, and close $S_1$. Now B and C will start up, and the speed and the current passing can be adjusted by means of the rheostats, $R_1$, $R_2$, and $R_3$. Both machines will then be running at full load both in volts and amperes and yet the power supplied from the auxiliary dynamo will only be equal to the total loss in both machines.

The following measurements must be taken: (*a*) the current, *c*, generated by the auxiliary dynamo; (*b*) the current, J, passing between B and C; and (*c*) the pressure, V, of the machines. Then, from the principle of conservation, the power lost is equal to that supplied, or the losses, L, for each machine are given by

$$L = \frac{c\,V}{2}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

The efficiency of each machine at a load J V is given by

$$n = \frac{J\,V}{J\,V + \frac{c\,V}{2}} \quad . \quad . \quad . \quad . \quad . \quad (2)$$

$$= \frac{J}{J + \frac{c}{2}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

If the machines are separately excited, the power taken by the shunt will have to be measured. Let it be *w* watts each. Then equation (1) becomes

$$L = \frac{c\,V + w}{2},$$

and equation (2) $$n = \frac{J\,V + w}{J\,V + \frac{c\,V}{2} + w}.$$

—Ernest P. Hollis.

*Answer to No.* 780 (*awarded* 7*s.* 6*d.*).—There are two methods of arranging the Hopkinson test. The first one consists of supplying the losses in the two machines by inserting an auxiliary dynamo in series with them, and in the second method putting it in parallel with them. The

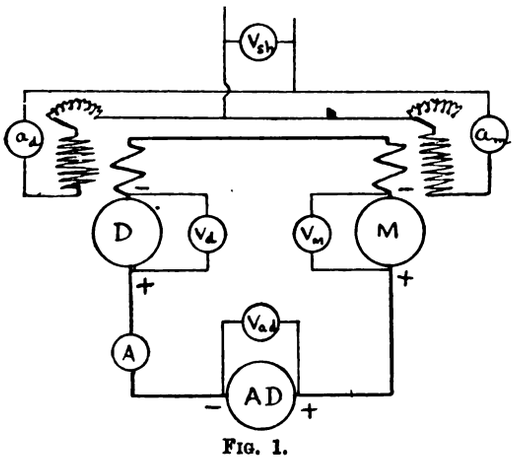

Fig. 1.

sketch (Fig. 1) shows the connections for the first case. It will be seen that the auxiliary dynamo has to carry the full-load current of the 900-kw. machines, so it will need to be a large-current low-voltage machine. In the second case (Fig. 2) the auxiliary dynamo will be of same voltage as two machines, but will only have to supply a small current. The choice between the two methods will be decided by what dynamo is available as an auxiliary machine.

Connect the two machines together mechanically if possible, as it is advisable to avoid belts. If they are designed for direct connection to engines, it will be an easy matter. If not, and their pulleys are made with spokes, the pulleys may be fastened together by means of clamps. Another way would be to take the pulleys off, and slip a steel sleeve over the two shafts, keying it on to each. The machine which is to act as motor must have its series coils connections reversed, so that the series coils will not be tending to counteract the effect of the shunt windings. The ammeters and voltmeters shown in diagrams will be needed, and a speed counter. It is usual to connect up the shunts of both machines to an external source of current having a steady voltage.

Assuming that the method shown in Fig. 1 has been adopted, we will now go into the question of starting up the machines and finding their efficiency. The machine M should be given a stronger field than machine D. The small machine, A D, is now started up with a resistance in series in order to prevent a rush of current. This resistance is gradually decreased until the two large machines have started up. In order to get the correct speed and full-load current, adjust small machine's pressure and increase the shunt current of machine M and decrease that of machine D more or less above or below the ordinary working shunt current. Take readings on the meters shown in sketch. The efficiency of the dynamo will be

$$E_D = \frac{A\,V_d\,100}{\left(V_d + \frac{V_{ad}}{2}\right)A + a_d\,V_{sh}}.$$

The efficiency of the motor will be

$$E_M = \frac{V_d + \left(\frac{V_{ad}}{2}\right)A\,100}{(V_d + V_{ad})\,A + a_m\,V_{sh}}$$

If the method shown in Fig. 2 is decided on, the main switch connecting the negative poles of the dynamo and

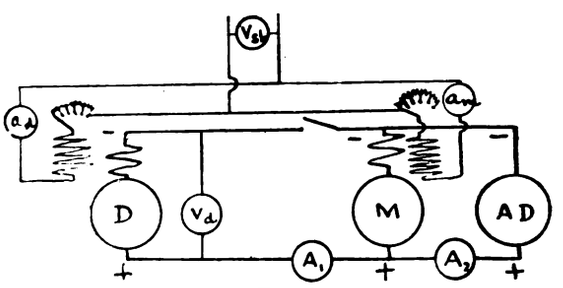

Fig. 2.

motor is left open and the motor started up from the auxiliary dynamo in the usual way. The dynamo being mechanically connected to the motor it starts generating, and when its voltage is equal to the voltage of the auxiliary dynamo the main switch is closed. The shunt currents of the dynamo and motor are now adjusted, as before described, so as to get the required current flowing through the armatures. The efficiency of the dynamo will be

$$E_D = \frac{A_1\,V_d\,100}{\left(A_1 + \frac{A_2}{2}\right)V_d + a_d\,V_{sh}}$$

and the motor efficiency

$$E_M = \frac{\left(A_1 + \frac{A_2}{2}\right)V_d\,100}{(A_1 + A_2)\,V_d + a_m\,V_{sh}}.$$

There is a good description of a Hopkinson test carried out at Crompton's works on two 800-kw. dynamos in the *Electrical Engineer*, vol. xxx., p. 150. There are also some particulars of this method of testing given in the *Electrical Engineer*, vol. xxviii, p. 888.—Research.

*Question No.* 781.—Describe with sketch the best vat to use for loading a 600-kilovolt-ampere 400-volt generator.

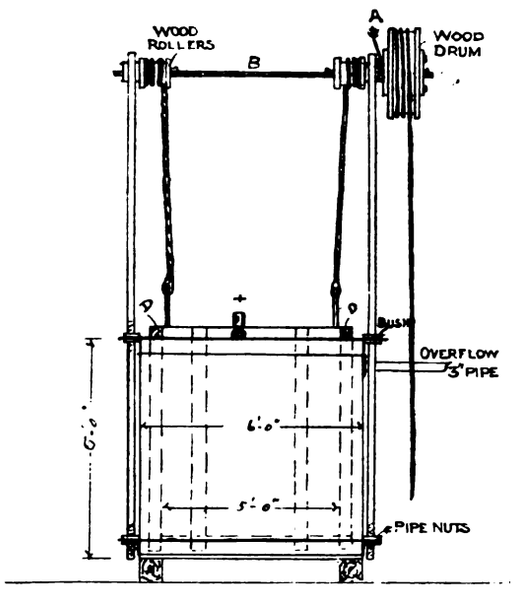
*Answer to No.* 781 (*awarded* 7*s.* 6*d.*).—Water loads for testing generators may be broadly divided into two classes—viz.: type A, those consisting of metallic plates dipping into water or a solution of salt, or sulphuric acid; type B, coils of resistance wire mounted on a frame or other suitable support, the coils being either air or water cooled. An example of each type is submitted; either of these is capable of dealing with the output from a 600-kw. generator.

*Type A.*—The containing vessel consists of a strong wrought-iron tank, strengthened with angle irons; size of

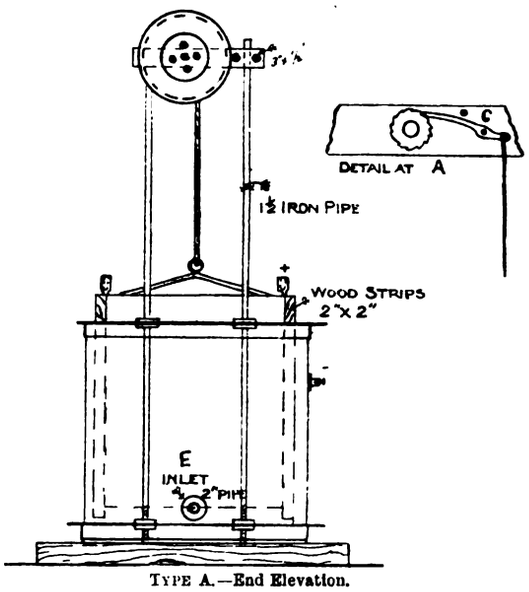
Digitized by Google

tank, 6ft. × 6ft. × 6ft. The inner and movable electrode also consists of a bottomless wrought-iron tank, 5ft × 5ft. × 5ft. 6in., capable of being raised or lowered by means of windlass, B, there being ratchet wheel at A to keep the tank at any given depth in the water. The ratchet is lifted out of gear when the inner electrode is required to be lowered by means of a cord, as shown in the detail of A. To the inner tank are screwed paraffined teak strips, 2in. × 2in.

To prevent the two electrodes coming into contact with one another, the supports for the windlass consist of wrought-iron gas-pipe 1½in. diameter, secured to bottom angle iron by means of pipe nuts. The bearing for windlass spindle is of iron plates, bolted to the top of the pipes. The amount of water flowing through the tank,



TYPE A.—Side Elevation.



TYPE A.—End Elevation.

and consequently the temperature, may be regulated by means of a tap on the inlet pipe, E. If it is desired to keep both poles of the generator insulated from earth, the tank must be supported on insulators, and the inlet and overflow pipes connected with the hydrant and drain respectively by means of rubber hose pipe, about 15ft. of 1in. pipe being suitable; if it is proposed to use other solution beside water, the outer tank would be better made of wood, and the movable electrode of lead if acid is used, as this is more durable under these circumstances. Iron plates are usually used for alkaline solutions, and lead plates for acid ones. In designing the above tank, the resistance of one square foot of hydrant water 1ft. thick was taken as equal to 100 ohms resistance; of course the resistance will fall as the temperature increases. The addition of foreign substances to the water enormously decreases the resistance, as the following tables show.

Solution of Salt and Water.

| Per cent. of salt. | Resistance in ohms per square foot 1ft. thick. |
|---|---|
| ·23 | 7·84 |
| ·46 | 4·65 |
| ·7 | 3·12 |
| ·93 | 2·38 |
| 1·16 | 1·9 |
| 1·39 | 1·48 |

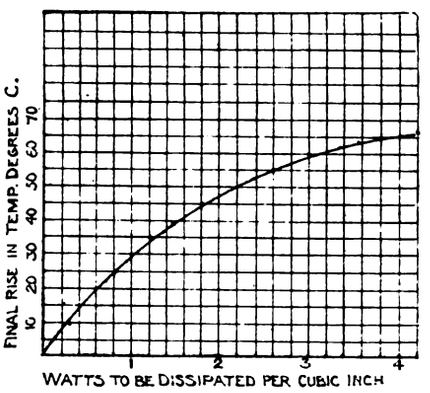
Solution of Sulphuric Acid and Water.

| Per cent. $H_2SO_4$. | Resistance in ohms per square foot 1ft. thick. |
|---|---|
| ·174 | 4·12 |
| ·43 | 1·75 |
| ·724 | 1·10 |
| ·985 | ·85 |

If a rise in temperature of T degrees F. are allowed, the water required to carry off the heat dissipated by one kilowatt-hour

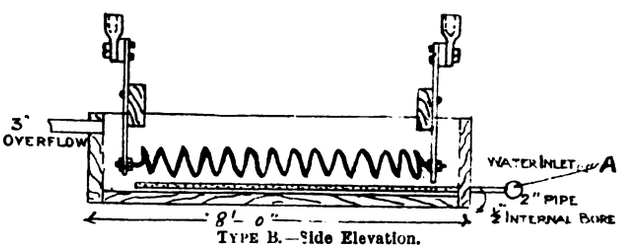
$$= \frac{34{\cdot}3}{T} \text{lb., or } \frac{34{\cdot}3}{T} \text{ gallons per hour.}$$

T = the allowable temperature of the liquid. When electrolytes other than water are used, continuous circulation of the solution is seldom possible, and curve No. 1 shows

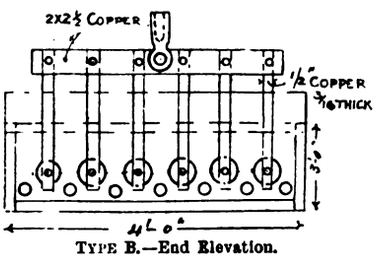


CURVE NO. 1.

the number of watts that may be dissipated per cubic inch of solution. A good margin should be allowed above the value shown for the curve, as several disturbing influences may slightly alter the results, such as (1) nature of tank, whether made of conducting or non-conducting material; (2) state of the atmosphere; (3) size of the tank, as a large tank will dissipate more watts per cubic inch than a small one; (4) back E.M.F. of cell, etc. A good average value is to take about 600 cubic inches of solution per horse-power dissipated. This will give good results for continuous running. For a stationary solution, of course, the tank will require to be larger than the above design.



TYPE B.—Side Elevation.



TYPE B.—End Elevation.

*Type B.*—This consists of coils of iron wire ·128in. diameter supported in a wooden box having a copious flow of cold water running through it. There are six spirals of wire, each spiral being about 65 yards long, the six being joined in parallel. The coils are joined to the terminal connection at each end of tank by means of copper strips ½in. × $\frac{3}{16}$in. The tank measures 8ft. × 4ft. × 3ft. To ensure an even distribution of the cooling water, the main delivery

Digitized by Google

pipe, A, branches out into seven ½in. pipes, perforated on the upper side; this gives a more even effect than one large pipe. This tank will, with about 30 gallons of water passing through per minute, deal with a load of 1,500 amperes at 500 volts for long periods with practically no deterioration of the coils. The formula for quantity of water required is the same as that given for type A, but a good margin should be allowed, as the whole volume of the water does not come into contact with the heated surfaces.—A. V. A.

*Answer to No.* 781 (*awarded* 7*s.* 6*d.*).—I will first of all describe a liquid resistance used in a large central station for occasional tests of dynamos up to 800 kw. In Fig. 1 is shown a front view and side view of the apparatus. It

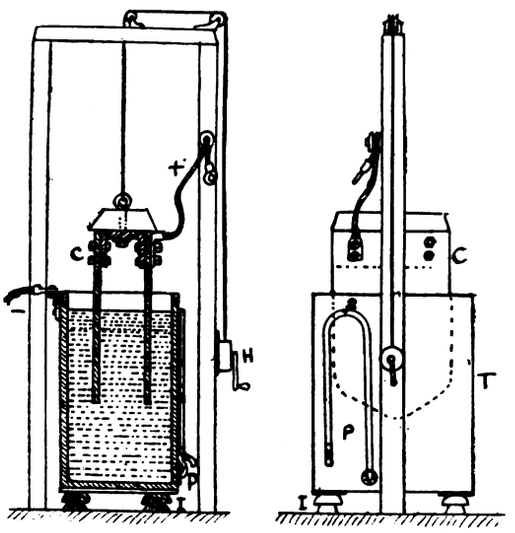


FIG. 1.

consists of an iron tank, T, supported on strong oil insulators, so as to insulate it from earth, as the tank is used as one pole. Two large cast-iron plates shaped as shown, C, form the other pole, and are suspended by means of a rope passing over pulleys at the top of the wooden supports. These iron plates are raised or lowered by means of a handle, H, fitted with ratchet, similar to the apparatus used for raising arc lamps. A flexible copper cable is fastened to the iron plates, as shown, and then fastened

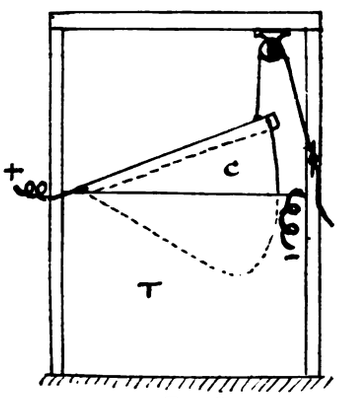

FIG. 2.

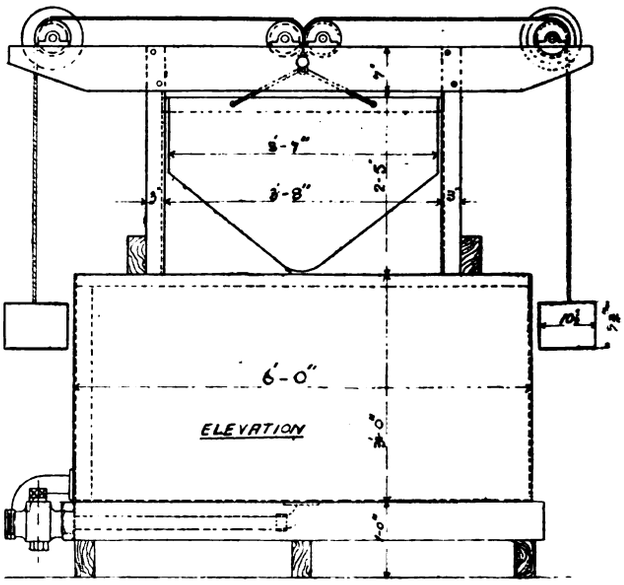
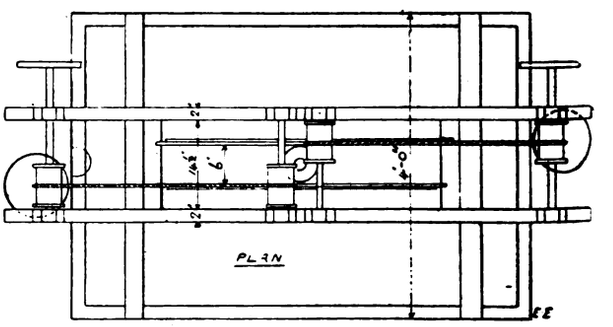
round an insulator. The end has a thimble sweated on to which the dynamo cable can be bolted. The other dynamo cable is connected direct to the tank. On a six-hour full-load test the liquid would gradually boil away. In order to keep liquid always at the same level and in constant circulation a pipe, P, is connected to the bottom of the tank, run up side of tank until proposed level of liquid is reached, then bent down again so as to form a siphon. If the tank contains more liquid than is required, the pipe, P, will siphon it off, and to prevent it acting after liquid has sunk to the proper level a small hole is drilled in the top of the pipe at S. This hole will stop the siphon action after a certain level is reached by allowing air into the pipe. As cold water is run in at the top and the water is siphoned off from the bottom of the tank, the contents can be kept cool. Canal water is used for filling the tank in question, it being found unnecessary to add any salt, as the water is impure enough without. If it is not desired to go to any great expense, the apparatus shown in Fig. 2 is very good for temporary use. The tank, T, is made of wood with a piece of sheet lead fastened to the two opposite sides and connected together to form the negative pole. Two pieces of lead or sheet iron, C, are fastened on either side of a piece of wood hinged at one end to one side of the wooden tank. These form the positive pole, and are raised or lowered by a rope passing over a pulley, as shown in sketch. The liquid soon gets very hot, and the current cannot be kept very steady during the test. I have, however, carried out a six-hour test of a 200-kw. machine successfully with it.—RESEARCH.

*Answer to No.* 781 (*awarded* 5*s.*).—A water resistance was constructed for use in testing a large number of 600-ampere 500-volt generators in the following manner. A galvanised sheet-iron tank, made of ¼in. plate, riveted together at the corners and well stayed, and mounted on a wooden stand, was used for the negative pole. The tank was provided with an overflow, a 2in. outlet pipe and cock at the bottom for emptying it, and ¾in. inlet pipe from the town's main. On the top of the tank was mounted a wooden structure, as shown in the sketch. Two sheet-





lead plates were used, each being ⅜in. thick, these being fitted with a wrought-iron bar at the top, each of which worked in a groove 1in. square cut in the uprights. The plates were counter-balanced by means of cast-iron weights, and wound up or down by the handwheels. The rope used was ⅝in. diameter hemp, well steeped in compound to preserve it from the steam. The positive main was taken to a stud on the wooden framework, and from there a number of smaller cables in parallel were used for joining it up to the plates. All the timber framework was well soaked in oil to preserve it from the wet. This arrangement was found perfectly satisfactory after exhaustive tests at a central power station in the Midlands.—C. G.

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

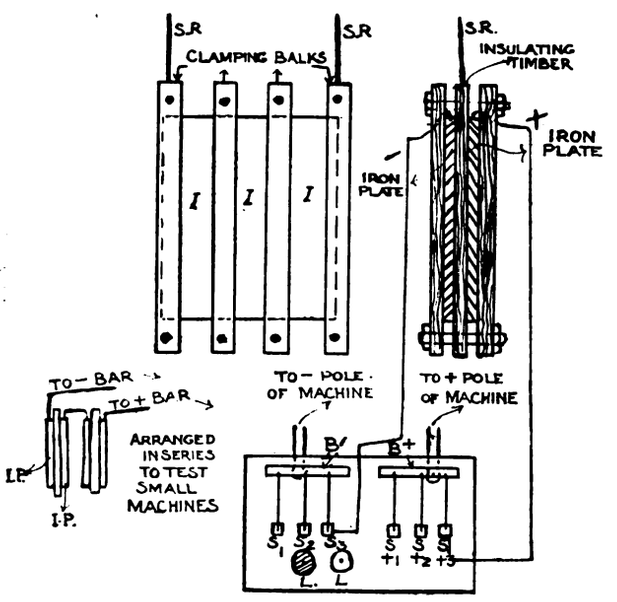
Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### ANSWERS.

*Question No.* 781.—Describe with sketch the best vat to use for loading a 600-kilovolt-ampere 400-volt generator.

*Answer to No.* 781 (*awarded* 5*s*).—The arrangement shown in the sketches is that in use at a fairly large power station for providing artificial loads for machines of from



250-1,500 kw. capacity. The sketch shows two wrought-iron plates (about 6ft. × 5ft.) insulated from one another by pieces of timber, and the whole held together by four baulks on each side, bolts running through the outside clamping baulk, through the insulating piece, and through the other clamping baulk. The whole arrangement is then suspended by the suspension ropes, S R, from the top of the settling tank for the circulating water supply to the condensers. It is usually worked with the plates completely immersed, as although the plates can be raised or lowered, it is found that, as the water from the river enters the settling tank at the bottom, when the plates are raised out of the water, the part exposed to the air becomes very hot, and consequently heats the surrounding water up, thus altering the load on the machine, the cold inflowing water, of course, staying at the bottom of the tank. Leads are taken from each plate, one to the bottom of, say, switch S+3, and the other to the bottom of switch S 3, these switches making contact with B+ and B−, to which bars the positive and negative leads of the machine under test are connected. Two, three, or as many of these plate arrangements can be suspended and immersed in the water as required, and in order to get sufficient load on they have only to be worked in parallel. The plates in use in this case are 6ft. × 5ft. × about $\frac{3}{32}$in., the insulating timbers being 2in. thick (the iron plates are, of course, shown out of proportion in the sketch for the sake of clearness), and this is found sufficient to deal with 1,300 amperes comfortably, thus easily finding load for a generator of 500-600 kw. at 550 volts, and for testing generators of 1,000 kw. and over two plates are worked in parallel on to the bars, B+ and B−, whilst for testing the 250-kw. generators two plates are worked in series as shown by the small side sketch. For the purpose of signalling from the switchboard to the attendant on the tanks, the two lamps, L L, are used, the hatched one being red; two similar lamps are also on the switchboard, and are connected into the same switches. When the load is getting too heavy the red lamp is lit up, and the attendant slightly raises the plates, the lamp being switched out when the load is right; similarly, the white lamp is used when more load is required. As mentioned before, these adjustments are comparatively slight, as, if the plates be raised too high (say above 3in.) out of the water, the load will not remain steady, due to the heating effect on the plates and the surrounding water. The chief object of the tank which is used for the purpose is, however, to provide water for the circulating pumps on the condensers, and, therefore, the entrance to the tank from the river is pretty low down. Were the tank designed solely for test purposes, arrangements would be made for the cold water to enter at the top; the circulation thus provided would neutralise most of the bad effect mentioned in this case.—W. T. W.

*Question No.* 782.—I want to connect a booster in circuit with one of the feeders in an alternating-current single-phase station, 2,000 volts earthed return. Should it be connected to the earthed or unearthed main, and why?

*Answer to No.* 782 (*awarded* 7*s.* 6*d.*).—It is usual practice to connect a feeder booster in series with the "inner" or unearthed conductor of a high-tension single-phase system, such as described by "G. E," and shown in Fig. 1. The

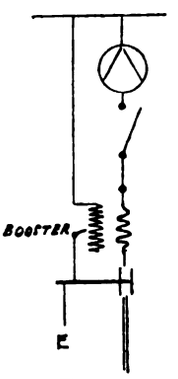


FIG. 1.

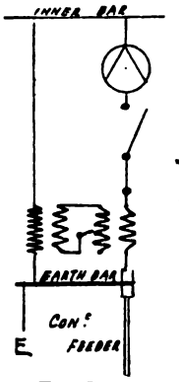

FIG. 2.

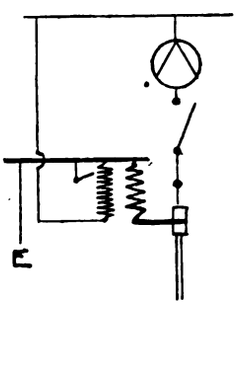

FIG. 3.

regulating switch is shown direct on the primary winding of booster, but sometimes, to avoid having regulating gear in direct connection with the high tension, the booster is arranged as shown in Fig. 2, so that regulation is effected on low-tension winding, thus rendering apparatus safer to handle.

There does not appear to be any theoretical reason why the booster should not be connected in circuit with the outer or "earthed" conductor, but it will be seen, on reference to Fig. 3, that if we connect it in this fashion there will be a difference of potential existing between the outer conductor and earth bar at the station, varying according to the amount of boost. Now it is correct to directly connect this conductor to earth at the station, and keep the difference of potential between this conductor and earth throughout the system at a safe figure to prevent any person receiving a dangerous shock from same.

Generally very little care is taken for the insulation of the outer fittings of dividing boxes, etc., even in some cases being left entirely bare, as they are only expected to be subjected to the difference of pressure existing between any part of outer system and station earth bar, and if one of these fittings should come in contact with earthed body, or outer of cable break down, the secondary of booster would be on dead short-circuit, its primary fuses would

Digitized by Google

blow and a sudden drop in pressure result, according to amount of boost at time of breakdown.—H. T.

*Answer to No.* 782 (*awarded* 7*s.* 6*d.*).—The booster should be inserted in the unearthed main, for if placed in the earthed main (as shown in Fig. 1) there would be the probability of having a heavy local current set up between the two sides of the booster through the earth. Even if the earthed main is only earthed definitely at the station, there is always the likelihood of its getting connected to

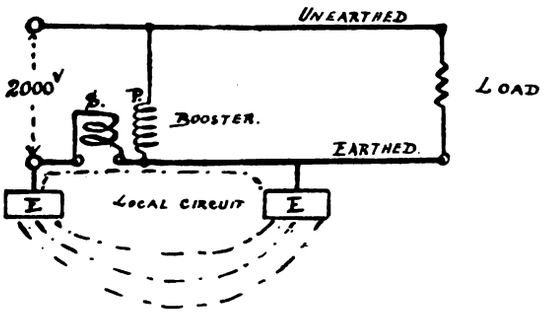

FIG. 1.

earth at some distant part of the line, and then the full booster volts (which in a 2,000-volt circuit may amount to several hundred volts) would be free to set up a current through the low-resistance circuit, consisting of the length of main between the two earthed points and the two earth connections. If the main is deliberately earthed all along its length, the connection across the booster secondary terminals, if inserted in the earthed main, would amount to a dead short-circuit.—Q.

*Answer to No.* 782 (*awarded* 7*s.* 6*d.*).—In nearly all the present-day systems of boosting on alternating-current supply systems, be they single-phase or polyphase systems, the general and principal idea, where ordinary static boosting transformers are installed and used, is to augment the pressure of supply by introducing the secondary of the transformer in series with the feeder, so that, to all intents and purposes, the secondary forms an integral portion of the feeder. This has the immediate effect of raising the potential of the feeder in question above the potential of the remaining feeder of the single-phase supply system, because there is induced in the secondary of the transformer a pressure which adds itself to that of the line.

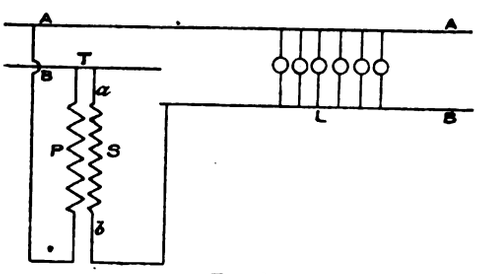

FIG 1.

In Fig. 1 will be seen a diagram representing the above system in a general manner, excluding details of the system. A and B are the two feeders referred to in the question; T is the static boosting transformer, with P as its primary and S as its secondary; L is a batch of lamps representative of the load. Suppose that the E.M.F. of supply before the transformer is reached is E volts—the virtual value is here referred to. Then there is impressed on the primary of the transformer a pressure of E volts. Let the ratio between the number of turns on the primary and those on the secondary be $\frac{1}{n}$; then the pressure induced in the secondary will be $\frac{1}{n}$ E volts, and this will augment the pressure of supply.

Firstly, let us suppose that the feeder A is earthed. It is clear this will have little or no effect upon the working of intermediary appliances in the system, such as the boosting transformer. The alteration in the conditions of working will not affect the primary of the transformer, because the earth will merely play the part of one terminal of such; and they will not affect the secondary, because this element has no immediate contact with the feeder A. Hence it—*i e.*, the booster—should be connected to the unearthed main, but this has not proved whether it is permissible or not to connect it to the earthed main.

Secondly, suppose that B (Fig. 1) is the earthed main. Then it is clear that the conditions of working are differentiated from those just considered. In the first place, however, it is evident that the working of the primary of the transformer will not be affected, but in connection with the secondary there is a different tale to tell. In this case, the terminals, *a* and *b*, of the secondary will practically be connected together through the medium of the earth, and the resistance of the intervening medium will be so slight as to produce a condition amounting almost to that of a transformer short-circuit. Now this would be objectionable for two prime reasons. First, there would be no augmentation of the pressure of the system, thus disposing of the use of the booster; and, second, the winding of the transformer might possibly be burnt out; or, if this did not occur, an abnormal amount of power would be absorbed by the transformer, producing waste, as well as a distorting and disturbing effect upon the working of the system as a whole. Hence we find that to connect the booster to the earthed main is to defeat the object in view.

The general conclusion, therefore, is that *the* policy is to connect the booster in circuit with the unearthed feeder—*i e.*, in circuit with B (Fig. 1) as the unearthed main.—G. W. BURLEY.

*Answer to No.* 782 (*awarded* 5*s*).—A brief consideration of the reasons for using the booster will help us to answer

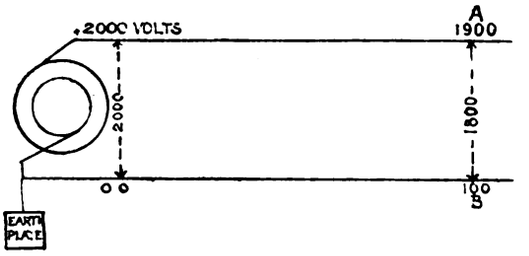

FIG. 1

this question. The feeder in which the booster is to be inserted is probably of considerable length and carrying a large current, with the result that there is a large voltage drop on the line and the pressure at the far end is considerably diminished. It has, therefore, been found necessary to raise the pressure at the far end of the feeder, as in all probability the feeder supplies a large number of arc lamps. This is accomplished by inserting a booster in the feeder.

I have assumed in Fig. 1 that there is a 100-volt drop in each cable for purposes of illustration. Therefore, we get a difference of pressure of 1,800 volts at the end of the feeder. Now let us suppose the booster is put on the unearthed main. It will, therefore, be seen that, as far as the actual working of the feeder itself is concerned, it is immaterial whether the booster is put on the earthed or unearthed main. There is, however, one consideration which decides the point. If the booster be put on the

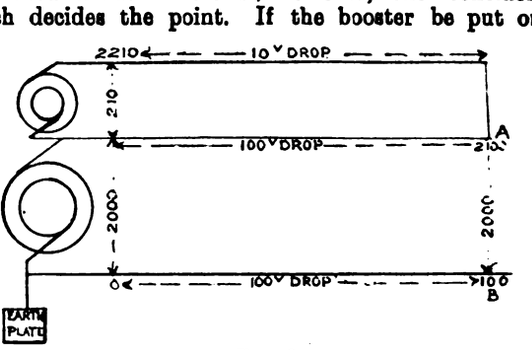

FIG. 2.

unearthed main, one terminal will be at a pressure of 2,210 volts and the other at 2,000 volts. The insulation unearthed side, and then the state of things will be as shown in Fig. 2. The booster gives an additional 200 volts pressure to the point A, making the pressure there 200 + 1,900 = 2,100 volts and the pressure between A and B

Digitized by Google

$= 2{,}100 - 100 = 2{,}000$ volts. This is, of course, what we want. Now let us suppose the booster is put on the earthed main. I think, without drawing another diagram, that it is obvious that the booster pressure will subtract itself from the pressure at B, which, instead of being 100 volts above earth, will be $100 - 200 = -100$, or 100 volts below earth, giving a difference of pressure between A and B of $1{,}900 - (-100) = 2{,}000$ volts. This result is, of course, the same as if the boosters were on the will, therefore, have to withstand a stress of 2,210 volts. If, however, it is put on the earthed main, one terminal will be at 0 volts and the other at 200 volts, and the insulation will have to stand only 200 volts. Now, of course, a machine designed to stand 2,210 volts will cost considerably more than one to stand 200, and the risk of breakdown will be considerably greater. It is obvious, therefore, that the booster should be put on the earthed main, being so connected as to lower the pressure at the point on to which it feeds.—ERNEST P. HOLLIS.

*Answer to No.* 782 (*awarded* 5*s.*).—I should certainly recommend the booster being connected on the unearthed main; one very important reason for so doing is that in most, if not all, certainly all the high-tension stations the writer has been connected with the earthed main is never fused, so that one end of your booster would be at earth potential and the other end would be so much above it, according to what voltage your booster was giving. It, therefore, only remains for someone to earth your main on the side of the booster which is above earth potential and your transformer or booster will be on dead short-circuit.

Another important point to be observed is the safety of the jointers when working on the mains. If the whole of the system is to be connected to the booster, then there is not so much chance of a mistake being made, but if, as is most likely, a particular district only is to be connected to the booster, then it is essential that great care be taken to switch off the booster as well as drawing the high-pressure main fuse before allowing men to work on the mains, as one is liable to get accustomed to think the outer is dead earthed when on the particular section the outer may be considerably alive. The writer had an instance of this sort occur in which a man was told the main was dead when it was very much otherwise; the matter was discovered in time, however. As far as the working of the booster goes, the writer sees no reason why it should not work as well on the earth as the unearthed side, but for the above reasons I should certainly recommend the connecting of the booster on the unearthed mains, then the same precautions would be taken—*i.e.*, the removal of the high-tension switch or fuse. The booster being connected between the machine and fuse would ensure the safety of all concerned, and the same purpose would be served.—W. H.

*Question No.* 783.—Certain motors and generators are fitted with a continuous ring, connecting all pole-shoes together. What is the object of this ring, and what is its effect on the working of the machine?

*Best Answer to No.* 783 (*awarded* 10*s.*).—The object of these iron or steel rings is to introduce a length of highly-saturated material into the path of the commutating flux, and so reduce the variations of this flux between no load and full load. Since the ring forms a magnetic short-circuit between the poles, practically the whole of the ampere-turns on two poles are effective in saturating the few inches of iron between the poles. Thus a dynamo having 5,000 ampere-turns per pole and, say, 4in. between poles would have $\frac{10{,}000}{4\text{in.}} = 2{,}500$ ampere-turns available per 1in. of ring between poles, and this value would produce an excessively high saturation in the ring.

Besides the flux which passes direct across from pole to pole through the ring, a certain proportion of the flux which enters the ring at the poles passes into the armature at the region about the neutral line, and forms the commutating field of the machine just like the fringe of flux at the edge of ordinary pole-pieces does. By shifting the brushes forward (in the case of a dynamo) they can be set so that the commutated coil lies in a flux just sufficient to produce complete commutation. This commutating flux will pass along a path, as shown by the dotted line in Fig. 1, and will be looped with the whole field ampere-turns (10,000), and with the whole armature ampere-turns, say 8,000 in this case, opposing the field ampere-turns. These net ampere-turns, of $10{,}000 - 8{,}000 = 2{,}000$, have to pass the commutating flux through the magnet iron, through a certain small length of the saturated iron ring at $a\ a_1$, and through the air-gaps at $b\ b_1$. Supposing 500 ampere-turns are sufficient to pass the necessary commutating flux across the two air-gaps, and that no appreciable ampere-turns are required for the magnet iron (yoke and poles). Then $2{,}000 - 500 = 1{,}500$ ampere-turns are available for the iron ring, so that the lengths of ring between pole and brush positions at $a$ and at $a_1$ can together absorb 1,500 ampere-turns, and since the ring takes 2,500 ampere-turns per 1in., the length of ring at each side can be ·3in., for $\cdot 3 \times 2 \times 2{,}500 = 1{,}500$. Now, at no load, if the excitation is unaltered, there will be the full 10,000 ampere-turns available for producing the commutating flux through the ·6in. of ring and the two air-gaps. This will lead to an increase in saturation in the ·3in. of ring at $a$ and at $a_1$, and a fall in saturation in the remaining 3·7in. of ring, so as to maintain the total 10,000 ampere-turns on the 4in. of ring. Suppose the saturation of the ring is such that an increase of the commutating flux to double its full load value is sufficient to absorb the $10{,}000 - 1{,}000 = 9{,}000$ ampere-turns in place of 1,500 in the ring. In spite of the fact that the commutating flux forms only a small

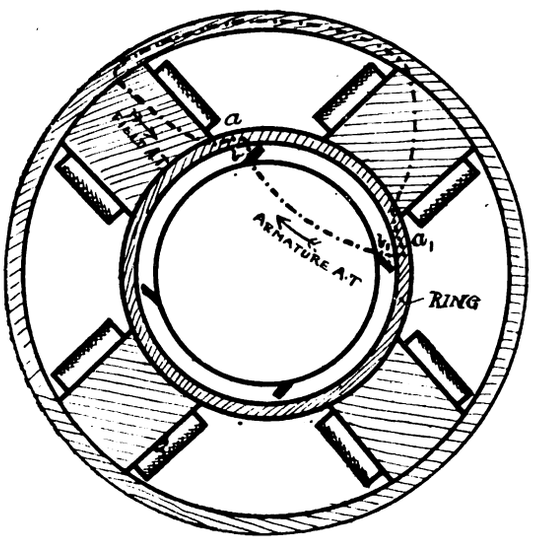

FIG. 1.

proportion of the total flux saturating the ring, it is quite possible for the doubling of this commutating flux to produce as large an increase in ampere-turns absorbed as this. In this case the commutating flux at no load would be to that at full load as 2 : 1. If no saturated iron were present, the commutating flux would be directly proportional to the ampere-turns available—*i e*, to 2,000 at full load and to 10,000 at no load—so that the ratio of commutating flux at no load to that at full load would in this case be as 5 : 1. The numerical values given are, of course, doubtful, but it is clear that the presence of saturated iron in the path of the commutating flux (especially if that saturation is to any considerable extent due to the commutating flux itself) tends materially to reduce the change of commutating flux between no load and full load due to armature reaction, and in this way helps towards a fixed brush position without sparking.

The same object is attained more or less satisfactorily in other designs by merely reducing the pole-tips to a very small cross-sectional area of iron, and so causing the ordinary working flux to saturate them. This avoids the additional magnetic leakage involved by the use of the rings, and at the same time makes the saturation of the pole-tip almost entirely dependent on the commutating flux, though this saturation does not reach so high a value as with the ring arrangement.—Q.

*Answer to No.* 783 (*awarded* 7*s.* 6*d.*).—The ring that connects the pole-shoes together is evidently what is known as pole bushing, and is to be found on machines made by the Allgemeine Elektrizitäts-Gesselschaft. It is of cast iron,

Digitized by Google

of small section, its object being to produce a gradual falling off of the magnetic field toward the neutral point, also to keep a stiff field, where necessary, and prevent overcrowding at the pole corners (Fig. 1). The generation of eddy currents in pole-pieces is greatest at the corners, owing to the sudden change of field and the crowding of lines. It is obvious, to prevent this, we must so arrange arrange the poles that a gradual falling off of the field takes place toward the neutral spaces, allowing the current in the armature section to build up and die away gradually, when the latter is entering a field of different polarity. The pole bushing attains this object, but has the disadvantage that there is no interpolar air space, the pole embrace being practically 100 per cent., thus making the adjustment of the brushes for varying load rather difficult.

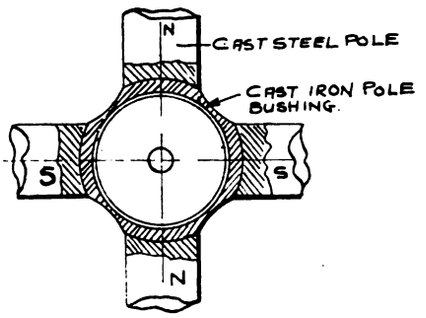

FIG. 1.

The crowding of the lines at the pole corners is produced by the reaction of the armature field upon the main field. When an armature is revolving in a magnetic field and carrying no current, the distribution of that field is uniform over the pole-face, as shown in Fig. 2, the dotted line representing the flux, but as soon as current is taken from the armature it resolves itself into a magnet, the flux of which (cross flux) acts across that produced by the main magnet, tending to displace it and twist it round in the direction of rotation (Fig. 3) in a dynamo. The flux distribution is no more uniform, but varies from a maximum value at the pole corners, A B, to a minimum at C D. It is obvious from this, that to bring the armature section in a proper reversing field for commutation, the neutral line, N N, will have to be shifted toward the direction of rotation in a dynamo and against it in a motor; thus the need for brush-shifting gear. In crane and tramway motors and all machines where fixed brushes are specified the amount of cross flux, due to armature ampere-turns, is kept very small, so as to interfere little with the original field.

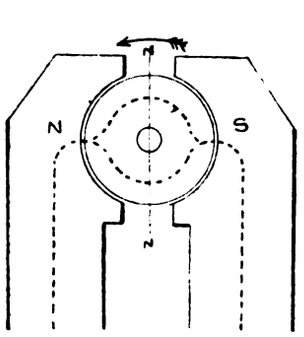

FIG. 2.

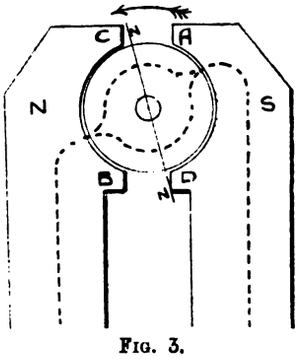

FIG. 3.

A good and much used method of keeping a stiff field and providing a good commutating fringe is to gradually increase the air-gap from the centre of the pole-face toward the tips, the armature then being eccentric with the bore. This has the advantage of confining the lines of force within the sphere of the pole-face, by proportionally increasing the reluctance toward the corners.—P. DEAN.

*Answer to No.* 783 (*awarded* 7*s.* 6*d.*).—The question does not state the material of which the ring is composed, but the object of fitting an iron ring to a dynamo or motor connecting all the pole-shoes together (as shown in Fig. 1) is to divert part of the magnetic flux from the armature. If it is required to saturate a field magnet by increasing the flux in it, without at the same time increasing the flux in the armature, it can be done by fitting one of these rings. For instance, we may suppose that we have a shunt-wound dynamo originally designed for 140 volts, and coupled direct to an engine. We now want the machine to supply a 100-volt circuit at the original speed and self-exciting. The voltage could be reduced to 100 by inserting resistance in circuit with the field winding, but probably

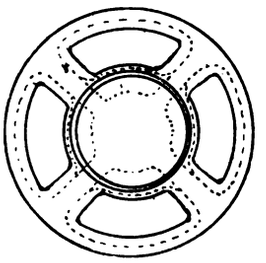

FIG. 1.

the machine would be unstable when working with such a weak field. If a small reduction in the speed or excitation took place, the voltage of the dynamo would drop away altogether. This can be explained by reference to Fig. 2, in which is shown Curve I, connecting volts and exciting ampere-turns at constant speed. When the machine was working at 140 volts its field magnet was fairly well saturated, but on reducing the excitation to get 100 volts the machine will be working on the straight part of the curve, where practically the only resistance

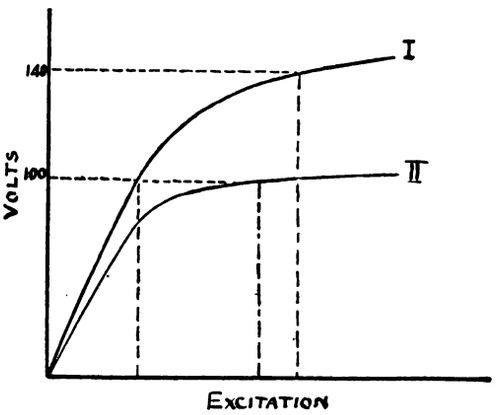

FIG. 2.

offered to the flux is the air-gap. Now, it is seen that when the machine is working on the steep part of the curve, a small alteration in the excitation produced by changing the speed or the regulating resistance in the shunt circuit will cause a rapid variation in the voltage. As a remedy, an iron ring can be fitted, and Curve II. will be the result. The exciting current for 100 volts will then be about the same as it was for 140 volts before fitting the

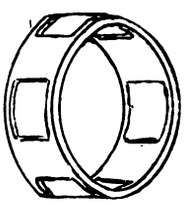

FIG. 3.

ring, and the machine will be perfectly stable. To get the full excitation with only 100 volts across the shunt, it may be necessary to connect the field coils in parallel. These rings have been tried as a preventive for sparking, but they have little or no effect in this direction. Some makers of motors and dynamos have adopted the arrangement for convenience of manufacture. All the pole-shoes are cast in one piece, with a thin bridge of metal holding them together, so that the whole can be readily machined and fitted in the magnet (see Fig. 3).—H. O. B.

[Other replies to Question No. 783 will be given in our next issue.—ED. *E. E.*]

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

### QUESTIONS.

791. Between the rails of a tramway system and the adjacent water-mains pressures up to ·25 of a volt are obtained when the generating plant is shut down. What do you consider is the cause of these potentials? There is an independent combined three-wire and alternating current supply in the town.—M. C.

792. In the Crompton automatic cut-out for automatically placing in circuit a substitutional resistance equivalent to the resistance of the arc, and which is used with 10-ampere, open-type, continuous-current street arc lamps, 10 in series on 460 volts, there are just two coils—one thick wire and one thin wire. The latter coil is in circuit the whole of the time, and apparently does all the work. Explain clearly the necessity for the use of the thick-wire coil, and also the functions which in this particular case it performs.—D. E. J.

### ANSWERS.

*Question No.* 783.—Certain motors and generators are fitted with a continuous ring, connecting all pole-shoes together. What is the object of this ring, and what is its effect on the working of the machine?

*Answer to No.* 783 (*awarded* 5*s*.).—This is one of the many devices which have been adopted to prevent sparking and at the same time keeping the cost of the machine low. The principal economy that can be effected in a dynamo is effected by having a large armature containing many ampere-turns and a weak field, but it is well known that such a machine will spark, for the armature interference will be great, causing the field to be distorted at high loads when a strong reversing field is required to overcome the large reactance voltage, and a very large lead of the brushes would be necessary in order to bring the short-circuited coil into a sufficiently strong reversing field. In order to make this more clear, let Fig. 1 represent a

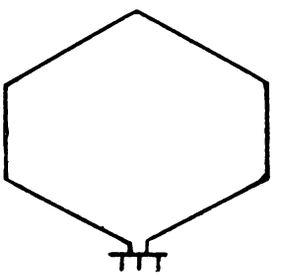

FIG. 1.

single armature turn connected to two adjacent commutator segments. Before coming in contact with the brush which short-circuits it, it has been carrying, say, 50 amperes in one direction and immediately after leaving the brush it is carrying the same current in the opposite direction. If this charge is to take place sparklessly, the coil must be traversing a magnetic flux of such strength and direction as to tend to reverse the current flowing in the coil, and the flux must be sufficiently strong to overcome the reactance voltage set up in the coil by the changing current, and the greater the load the greater the reactance voltage; therefore a stronger reversing field is required.

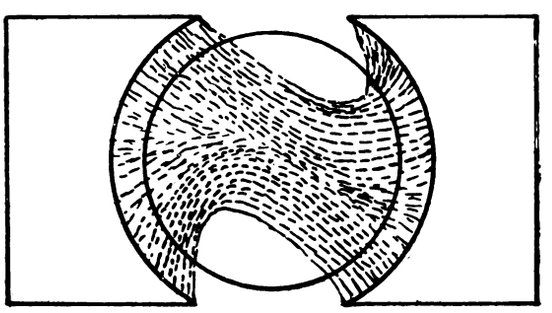

FIG. 2.

Now, it is well known that at high loads the field becomes distorted similar to Fig. 2, and it is necessary (in the case of a dynamo) to shift the brushes forward so as to bring the short-circuited coil into a sufficiently strong reversing field; but if this field distortion can be lessened in any way, the amount of lead required will obviously be reduced, and the machine will be less liable to spark with varying loads. This is not a difficult problem, although to do it well adds considerably to the cost of the machine, for the ampere-turns on the armature should be small as compared with those on the field, and the armature coils should have low reactance voltage; but in order to keep down the cost a number of inventions have been brought out for reducing sparking, and the ring of iron short-circuiting the poles described in the question is one of them. This ring forms a path of low reluctance for the magnetic lines, consequently they and the portion of the pole-pieces forming them are highly saturated. Hence the field is stiffened, and the armature cannot distort it to anything like the same extent, and from what has been said this will clearly help to minimise sparking.—E. AUSTIN.

*Answer to No.* 783 (*awarded* 5*s*).—The fitting of pole-rings is but one of the many devices that have been introduced for reducing the effect of armature reaction. The employment of these rings, or cast-iron bushes, is due to Dobrowolsky. Sometimes, instead of a complete ring, bridge pieces are fitted; these bridge pieces are fastened to the pole-horns in a somewhat similar manner to the well-known brass plates or grids that are to be seen on nearly every dynamo. The principal function of these rings is to prevent an abrupt change of magnetic line density at the trailing horns. They cause, so to say, a shading off in the density of the lines that are more or less crowded at the trailing horns. The more abrupt the change of density of the magnetic lines, the stronger the eddy currents in core and armature winding; therefore by gradually weakening, instead of suddenly changing the density of these lines, there is proportionately less danger to be feared from eddy currents. There have been many other methods suggested for obtaining this object, of which the following are the leading devices. Cast-iron shoes are fitted on the poles, the lower permeability of this metal in comparison with wrought iron preventing any abnormal crowding of magnetic lines at the polar horns; instead of the polar horns being parallel with the axis of the armature, they are sometimes cut off at an angle, or made V shaped. Another well-known method is to have the magnets bored to a larger diameter, by inserting packing pieces, so that when brought to their proper positions the air-gap gradually increases towards the horns. Some makers slot the pole, so that the trailing horn is but a comparatively thin slice, easily saturated. The use of these pole bushes is then a means whereby we may minimise the effect of eddy currents by preventing too great crowding of magnetic lines; the field falls off gradually instead of suddenly changing in strength. This advantage, however, is only obtained at the expense of limiting the amount of displacement that may be given to the brushes without sparking. In other words, the non-sparking angle through which the brushes may be moved is considerably reduced. When machines are fitted with these rings the brushes require careful adjustment. In practice, such machines are usually fitted with brushes of the "fixed position" variety.—M. M.

*Question No.* 784.—The system known as the free-wiring system has now been in vogue in certain towns for upwards of five years. How does it satisfy (1) the consumer; (2) the supply company; (3) the local contractor; and how are difficulties caused through tenants leaving and the new tenants refusing the use of the light adjusted?

*Best Answer to No.* 784 (*awarded* 10*s*.).—Before answering query No. 784 it is first necessary to consider by whom the so-called free wiring is carried out. So called, as it in reality amounts to an electric light system on the instalment plan. Free wiring may be generally divided into three classes, and the satisfactory result—apart from the demand for energy—to the supply company and the local contractors is entirely dependent on which class the system belongs to; the consumer is practically unaffected by those considerations: (Class 1) free wiring by a private firm, or more usually a local company having arrangements with the supply company; (Class 2) free wiring by the supply company solely as contractors; (Class 3) free wiring by the supply company, sublet to local contractors.

Digitized by Google

*Case* 1.—The free-wiring firm having entered into an agreement with the supply company, carry out all free-wiring work, meet all expenses in connection with same, receiving in return a small sum per unit, say from a fraction of a penny to 1d. on current consumed by the party who occupies the premises so free wired. This, of course, extends only to a certain time proportionate to the size of the job, the probable current consumption, etc. The firm's money is thus simply invested in the premises, and in time is duly paid off plus a percentage varying, say, from 33⅓ to 40 per cent. This arrangement is usually satisfactory to both supply company and free-wiring firm, to the former because it speedily brings consumers, and to the latter as they, by waiting for payment, secure a larger percentage than in ordinary contracting work; they also have the further advantage of being the free-wiring firm, a fact which appeals to small shopkeepers, etc. The local contractors naturally oppose this system, as the free-wiring company, owing to their contract with the supply company, are able to secure the greater portion of the wiring work, the local men being, so to speak, cut out by the combine. The local men usually retaliate by making more or less exaggerated statements to prospective clients of theirs regarding the ultimate cost of free wiring, and argue the consumer pays for the cost within a year, but this is more a matter for the owner's consideration than the tenant. Placing the parties interested in the relative order of best results from the system: (1) the supply company; (2) the free-wiring company; (3) the consumer; (4) the local firms.

*Case* 2.—The foregoing remarks apply to this case also, but it is still more profitable to the supply company, any gain accruing going direct to them without a third party's intervention. The supply company are obliged to keep a staff of wiremen to carry out the wiring work. In the writer's opinion, this is very unfair to the local contractors, who are completely restricted to jobs they personally come in touch with. (Readers well understand this only refers to free-wiring work.) The supply company may allow a commission on work introduced to them, or allow the local man who so introduces a consumer to carry out the work for them, but when the station is a new one the tendency is for parties desiring an installation to apply direct to the station engineer, who is probably after circularising the town or city, and holding lectures and demonstrations to popularise electric light and power. It is not unusual in this case for the supply company to undertake lamp renewals. It is regrettable to say in some cases the lamps supplied are of a low efficiency, which fact need not be commented on. The writer has one case in mind where the direct consequence of the supply company carrying out all its own wiring work was the formation by local contractors of a rival free-wiring company!

*Case* 3.—This seems to be about the most satisfactory arrangement possible with free-wiring systems. Contractors in touch with intending consumers who desire free wiring price the job, and then send their estimate to the supply company. If the price is right, the supply company accept, and pay the contractor on completion. If the estimate submitted is too high, an effort at a compromise is made. In any case the contractor has his commission. The supply company sometimes go one better, and specify some particular wire and accessories which they keep in stock, and sell to the local contractors at a small percentage over list prices. In the event of a private party approaching the supply company for a free installation, tenders are invited from, or the work given to, some of the local firms. Naturally, owing to the middleman—as represented by the supply company—the contractor's profits are not as satisfactory as if dealing direct with the consumer, yet this arrangement is about the best that can be arrived at in such cases. Now the foregoing methods evidently affect the consumer but little. In every case he or his landlord pays a slight extra charge, either per unit or in some such manner. Instead of fixing this extra charge per unit, some supply companies have slot meters fixed on all free-wiring jobs, unless there are a large number of lamps. The slot meter gives about five hours' use of a 33-watt lamp for 1d., and so in time balances the original cost of the installation, which, of course, still remains the property of the company. The question of tenants leaving is a rather delicate matter to settle, still the company have some strong points in their favour: (1) the installation is their property, and can be removed by them; (2) probably, when installing same, they insisted on other illuminants, such as town gas, acetylene, etc., being altogether removed; (3) if the original tenant has been using the electric light for a reasonable time, the extra charge, meter rent, etc., has probably refunded a considerable amount, if not all, of the initial expenses; (4) they probably have the house-owner's signature to the agreement. Taking an extreme case. Tenant "A," for whom the wiring was carried out, leaves after, say, 12 months. Tenant "B" objects to the electric light. The house or shop is more than likely renovated and painted during the interval between A and B's occupancy. When the engineer, in the course of a tactful interview with "B," points out it will be necessary to lift floors, etc., to get the wiring out, also that the gas is disconnected as far as the street, etc., "B" generally comes round to looking at things the right way. If he still remains obstinate, and no agreement exists with the landlord, the fittings, etc., could be removed as far as possible, and the wiring left intact for future use. This is, however, a rare occurrence, new tenants generally accepting things as they find them. Further, it is the average that must be considered, not the individual. Concluding, the writer trusts other parties interested in this subject will put their views forward, and would like to mention that from a contractor's point of view he regards all free-wiring systems with disfavour.—J. E. H.

*Answer to No.* 784 (*awarded* 7*s.* 6*d.*).—"Free-wiring' schemes have now been in operation considerably longer than the period mentioned in your query, the first scheme being initiated some seven or eight years ago. The author is assuming, however, that your querist refers to a scheme carried out by some so-called "free-wiring" company, and not by the supply authorities themselves, as few municipalities, at any rate, have obtained the necessary powers.

Dealing with the first of the points under consideration—viz., the consumer—it can hardly be said that "free-wiring" schemes are satisfactory in the long run to this much oppressed individual. In return for the wiring of his premises, the consumer must enter into an agreement (about which he understands practically nothing, and which he probably never reads) whereby he undertakes to pay an extra charge, over and above the supply charges, of, say, 1d. or ½d. per unit, as a rental on the installation. This rental, of course, is dependent upon his consumption of electricity, but he must make a minimum payment per annum of from 9d. to 1s. per 8-c.p. lamp installed. The consumer has also the option of purchase of the installation at the expiration of four or five years, but until he does so he is never any nearer owning the installation, and should he at any time cease to use electricity he still remains liable for the minimum payment. Then, again, difficulties arise when any change of tenancy occurs. If the incoming tenant signs a new agreement, all well and good; if, however, he refuses, and decides to rewire the premises himself, the "free-wiring" company appear to have no option but to remove the wires and fittings from the installation at their own expense. It is claimed, however, by the company that a tenant is responsible for the minimum payment until the new consumer signs an agreement, or until the tenant purchases the installation. In this case, of course, the only course open is for the new tenant to remove the wires and fittings from his premises, and by so doing he immediately absolves the original tenant from any further claims. If, however, the consumer removes into new premises, and the premises that he has vacated remain empty for any length of time, or if the incoming tenant refuses to sign the "free-wiring" agreement, he is still held responsible for the minimum payment in connection with these premises. The "free wiring" company undertake to keep the installation in a proper state of repair for a period of six months from the date that it was put in; it follows that should a new tenant take over the installation at any time, he does not feel inclined to carry out any repairs to an installation that is not his own, and that he will afterwards have to pay a rental on.

Digitized by Google

Regarding query No. 2—viz, the supply company—they are certainly benefited during the first year or two of the scheme, as by means of it they obtain a large number of customers who, in the ordinary course, could not afford the expense of wiring their premises outright, and would probably never become consumers of electricity. It is usual for the supply company to collect the rentals of these "free-wiring" installations with their quarterly accounts, and then to hand them over to the "free-wiring" company. By so doing, the supply company have to bear the burden of all the numerous disputes which from time to time arise, and which certainly do not tend to maintain a good feeling between the supply authority and the consumer. Should a consumer make extensions to his installation and decide to have these extensions carried out by a local contractor and paid for direct, complications are again liable to ensue. Two meters must now be put into the installation where one would suffice—one to register the consumption on the "free-wired" installation, and one for the consumption on the consumers' own wires and fittings. This naturally means extra expense for the supply company, and in a large undertaking entails considerably extra clerical work. If an extra price per unit is charged as a rental on the "free-wired" installation, the use of prepayment meters for these consumers is debarred, unless the supply company are prepared to go to the trouble of having certain of their meters calibrated for a higher rate per unit. Touching now upon the third point—viz., the local contractor—the adoption of a "free-wiring" scheme acts as a stimulus to him, and the competition that ensues, of course, benefits the supply company. The local contractor, as a rule, has a very poor opinion of those consumers who get their installations wired "without paying for them." The author is of opinion that some form of hire-purchase system should be adopted by the supply authority itself (either company or municipality), with carefully drawn and not too stringent regulations, as it is only by these means that small householders and shopkeepers can be induced to adopt electricity as an illuminant.—T. S.

*Answer to No.* 784 (*awarded 7s. 6d.*).—In towns where a gas supply exists, the gas-pipes are, as a rule, laid in a house during its erection, the expense being borne by the landlord, and forming part of the initial cost of the house. The interest on the extra outlay is, of course, included in the rent. The fact that, as a rule, a tenant desirous of having his house lighted by electricity must have it installed at his own expense, handicaps the electric supply companies in their competition with the gas interests. In order to overcome this difficulty and to increase the number of consumers, the supply companies in certain towns have adopted the free-wiring system in various forms, and with varying success, largely depending on the locality. An agreement must be signed by the landlord of the house giving his sanction to the wiring of his premises, and also by the tenant, who undertakes: (1) to keep the installation in repair, except in cases arising, within a reasonable period, from faulty material or workmanship; (2) to pay a minimum quarterly charge for energy. The installation remains the property of the company, unless, as sometimes happens, a consumer afterwards buys it over.

There are two alternative schemes adopted by certain companies for free-wiring. By the first, a consumer has his house wired throughout, free of cost, on agreeing to pay an extra charge—about 1d. per unit—on energy consumed, as interest on the outlay. By the second scheme, a certain number of lights are installed free in parts of the house to be selected by the company, the lights being placed, of course, where they will be most used. In the first case, the extra charge per unit covers the interest on capital spent and depreciation; in the second, the company gains nothing beyond an additional consumer and a maximum of demand to repay the cost of installation. Besides this, there is often difficulty in persuading a second tenant to take over his predecessor's agreement and to use the lights, and his refusal involves considerable trouble and loss to the company, who either have to let their installation lie idle or remove it at fresh expense. There are also people so constituted as to prefer not paying their lighting bills on leaving a district, and, having nothing to lose in the way of fittings, they have no hesitation in leaving behind them, with an unpaid bill, an installation which cost them nothing. From the consumer's point of view, the free wiring system cannot be otherwise than satisfactory. He has no initial outlay, no trouble nor responsibility in fixing his lights nor in removing his installation when he leaves the house. He is apt, however, to overlook the fact that the extra charge per unit, where it is added, is interest on the capital expended by the company on his installation, and includes it in his lighting charges, which then appear extravagant. It is often difficult to convince him that he is not being overcharged. In comparing his lighting account with his neighbour's gas bill, he is apt to forget that, while his neighbour pays indirectly for his gas-pipes, etc, *to his landlord*, who included the interest on that outlay *in the rent*, the cost of his own electric lighting installation is *not* included in the rent, but in his lighting account, in the shape of the extra charge per unit. In the case of a consumer who has a certain number of lights placed free of cost in approved positions, he often grumbles because he may not choose their positions, etc.

Of course, the adjustment of these difficulties, as of any others, depends largely upon the tact and management of the company's representatives. The success or failure of the system will be affected by local conditions. In a district with a "floating" population, where houses frequently change hands, it is not in the company's interest to advocate free wiring. The risk is too great, and the troubles with new tenants too numerous. In districts where most of the inhabitants own their dwellings, the case is different; for once the installation is made, the expense and trouble, so far as the company is concerned, are usually at an end, the interest on the outlay being included in the quarterly lighting account. The local contractor is often invited to quote special rates for the whole of the company's free-wiring work, and as the system attracts consumers who otherwise would not call in his services, he cannot but be satisfied. There can be no set rule for the adjustment of free-wiring difficulties, so much depending upon the local conditions, the tact and patience of the company's representatives, and the commonsense and fairness of the consumers. In towns where the system has been tried it is a mere matter of speculation, working out to the company's advantage in one case and proving, perhaps, a dead loss in another.—H. J. W.

*Answer to No.* 784 (*awarded 5s.*).—The system known as free wiring has, in most towns where it has been adopted, proved satisfactory on the whole. In order to obtain some idea of how free wiring affects the various parties concerned, it is necessary to consider the different methods by which it is applied. These may be summarised as under, the cost of the installation being recovered from the consumer in one of the following ways: (1) by a fixed rental being charged for his installation; (2) by a small additional price per unit for energy consumed; or (3) by the payment of instalments at fixed intervals, sufficient to wipe off the capital cost and interest after a certain number of years. In addition to the above methods, which have generally been adopted, there are one or two free-wiring companies in existence which undertake the wiring of premises on the repayment system, either direct with the consumer or through the supply authority. This method has, however, proved unsatisfactory to the local contractor owing to the unfair competition it creates, and is also troublesome to the supply authority, but has, so far as the author is aware, only been carried out to a small extent.

In any of the three chief methods enumerated, the installations may be carried out by the supply authority itself or through wiring contractors, but the latter is advisable so as not to create unfair competition and dissatisfaction amongst the wiring contractors, who really act as canvassers for the supply authority. The author knows of one city, though not in Great Britain, where the supply authority itself carries out the whole of the installation work for lighting, power, and any other supply, there being no outside wiring contractor. The introduction of free wiring (No. 3 method being adopted) has been very satisfactory, and has resulted in a large increase of custom, most consumers adopting the deferred payment system in preference to payment on completion.

In comparing the three methods quoted, No. 3 would

Digitized by Google

appear to be the most satisfactory. Nos. 1 and 2 have the disadvantage that the installation always remains the property of the supply authority, whereas in No. 3 the installation belongs to the consumer after a certain number of years (usually not exceeding 10). All three methods are about equally satisfactory to the consumer and local contractor, as, providing the carrying out of the installations is left in the hands of the local contractors, all the methods benefit them, and it matters little to the consumer whether he pays rental, a little more per unit, or purchases by instalments.

There seems to be no doubt that wherever any of these systems have been adopted satisfaction has been attained all round. By their means electric light has been brought within the reach of many consumers who could not otherwise have afforded the necessary initial expenditure, and so-called free wiring has thus resulted in access of business to wiring contractors, and an increased load to the supply authority, making it possible to generate at a reduced cost per unit, and so cater for more custom. The consumers thus obtained are very often long-hour ones, although small, and are thus, perhaps, more profitable than many of the larger consumers.

As regards tenants leaving, little trouble is experienced, as the owner is generally a party to the agreement, and the new tenant, more than likely, will be only too pleased to avail himself of the electric light without a heavy initial expenditure. Should, however, any difficulty be experienced, the supply authority can take away all the fixtures, having previously charged the former tenant for any damage done during his tenancy. The cost of removing the fixtures is very small, and as probably a good proportion of the capital has been already repaid, the loss, if any, to the supply authority is practically nil.—H. A. N.

*Answer to No.* 784 (*awarded* 5*s.*).—Before answering the question in detail, I will give a short description of the system with which I am acquainted. The company undertake the wiring of premises, without initial cost to the consumer, under a rental system. In the two or more living-rooms plain three-light spider fittings are placed, and pendants in all the other rooms. A small Nernst lamp is, however, placed in one of the living-rooms, if required, fitted with a counterweight to work up and down, instead of the three-light fitting. Application forms must be filled in and signed by both the tenant and the landlord. The rental is 3d. to 4½d. per lamp per quarter, according to the easy or awkward position of the lights. Lights will be fixed in such rooms and passages as are in regular use and are likely, in the opinion of the engineer, to be of permanent utility. Consumers will be allowed the option of purchasing the installation either by a lump sum or by increased rental for a term of years. The installation must not be interfered with by anyone except the employés of the company. A rental is charged for all meters, unless of the prepayment type. Originally this system was worked on a different scale, the consumer paying no fixed rental, but was charged 1d. more per unit than the ordinary consumer. This was abandoned about a year ago, and the above system of rental established.

With regard to the consumer, it must be borne in mind that those who use this system of wiring are mainly of the working class or small tradespeople. They, therefore, are able to obtain a good, clean, safe, and convenient light without any initial outlay. The supply company, although not making an immediate profit, are, however, receiving interest on the outlay involved in installing the system, and are also getting an increased consumption of current, as these consumers would not make use of the supply if they had to pay for the wiring before they could use the light. The company are, therefore, or ought to be, satisfied. The local contractors, although at first a little nettled at seeing the company's wiremen doing so much work, have now seen that they have no cause to grumble. As I have stated before, the majority of the consumers on this system would not be able to spend a lump sum of money in installing the light, and so the local contractor is not losing customers through the company having power to wire houses on this system. In some places, however, I understand that the supply company put the work out to the local contractors at fixed prices. When a new tenant goes into a house wired on this system, and does not require the use of the light, all the fittings and pendants and the meter are taken down, and permission is generally granted to leave the ceiling roses, switches, and fuse boxes, as the landlord has signed the application form of the outgoing tenant, and so fully understands his position in case of that tenant giving notice. Although very rare, it has sometimes occurred that the whole of the wiring has to be taken out, owing to the new tenant desiring to use gas, and this, of course, means a severe loss unless the outgoing tenant has been in the house for several years.

On the whole, I may say that the consumers give very little trouble, and the system is working very satisfactorily. In conclusion, I must state that the present number of consumers on this system is about 1,500 out of a total number of about 4,000.—J. LLOYD.

*Question No.* 785.—It is noticed that dust collects much more on the positive than on the negative 'bus bars in a central station, also that it collects on the glass panes opposite the bars, and that more collects opposite the positive bar than the negative. How is this explained?

*Answer to No.* 785 (*awarded* 5*s.*).—In considering this question a few remarks may be made as regards so-called "positive" and "negative" electrification. Generally speaking, the rate of loss of charge from a charged conductor is proportional to the difference of potential between itself and its surroundings, but has been found to be much greater from "negatively" electrified surfaces than from "positively" electrified ones. This and many other phenomena appear to indicate that the so-called "negative" electrification is really the state of excess—*i e*, that in which there is *more* electricity than in the surrounding space—while the so-called "positive" electrification is a state of defect, or a state in which there is *less* electricity than in the surrounding space. For example, Crookes's experiments with vacuum tubes show that molecules are driven from the negative electrode towards the positive, the vanes of a little fan being repelled from the negative pole. Now, the negative main of a two-wire supply system, even if unearthed, tends to assume a potential near that of earth, which is evident to anyone from the fact that a shock is generally obtained from the positive to earth. Therefore, if "negative" is really the state of excess, there would tend to be a transfer of electricity from earth, and from the negative 'bus bar through the air to the positive bar. Further, it is a well-known scientific fact that in fine dry weather or in dry situations, when dust tends most to float in the air, the earth is "negatively" electrified relative to the air. Particles of dust, therefore, coming from the earth or objects in contact with it would be negatively electrified, and as the negative main and earth are at or near the same potential, these particles would, by virtue of their charge, be attracted to the positive 'bus bar. It is also possible that particles of dust, uncharged, floating near the negative bar, might be negatively electrified, repelled, and afterwards reach the positive. *This* action might also go on in the reverse direction, from positive to negative; but as the rate of loss—as already stated—is greater from the negative, the net result would be to transfer electricity—carried by dust particles—from negative to positive.

The question does not state whether the glass panes opposite the bars are those of windows, meter cases, or otherwise; but it is conceivable that the glass, which in itself is a good insulator, either is itself or has the dirt on its surface *locally* electrified by induction from the 'bus bars, and the free charge, repelled from the 'bus bars and of like sign to those of the 'bus bars, would have the same effect on dust particles as have the 'bus bars themselves, as explained above. As glass is "positively" electrified relative to cotton, silk, and most other substances on being rubbed by them, a more practical explanation is that the cleaning of the glass causes it to be "positively" electrified, and this, taken in conjunction with the charges induced locally by the 'bus bars, would cause an excess of "positive" charge opposite the "positive" 'bus bar over that opposite the "negative" 'bus bar; thus the glass locally will act on dust in the same way as the 'bus bars themselves.—R.

[Other replies to Question No. 785 will be given in our next issue.—ED. *E. E.*]

## QUESTIONS AND ANSWERS.

If thou hast knowledge, let others light their candle at it.

Under this heading we insert questions and answers of a practical character relating to central-station work, tramway work, or construction work; and for each suitable question offer *one shilling*, and for the best solution of any question we offer *ten shillings*. We also give *five shillings* for every other answer we print. The answers to any questions should be sent within ten days after the question has appeared. The replies should deal concisely with the points at issue, and should not exceed *about one thousand words in length*. Discursive answers are apt to be discarded, owing to the space they would occupy.

We would call the attention of those sending in answers to the fact that the neatness of any sketches (which must be in *ink*) sent in is considered when marking the relative values of these answers. All formulæ should be carefully written to prevent mistakes as to symbols, and all loose sketches should be signed by the author. The matter must be written on one side only of the paper. Questions may be sent at any time.

### QUESTIONS

793. A battery working in conjunction with a reversible booster on a traction load has recently been overhauled and all sediment removed from bottoms of cells. Since then it has been noticed that large lead trees have been forming on a lot of the negative plates, causing a lot of trouble by short-circuiting cells. Would the fact of using acid out of an old battery, that has been idle for months, to top up the cells after overhaul cause the trouble, and could some reader give a remedy for same; also explain the cause of trees forming?—A. B. C.

### ANSWERS.

*Question No.* 785.—It is noticed that dust collects much more on the positive than on the negative 'bus bars in a central station, also that it collects on the glass panes opposite the bars, and that more collects opposite the positive bar than the negative. How is this explained?

*Answer to No.* 785 (*awarded* 7*s.* 6*d.*).—I have noticed for some considerable time that dust seems to collect on switchboards on or near to the 'bus bars and their connections. Some time ago, A. A. Campbell Swinton drew attention to the fact that some flexible wires in his office were clean while others always seemed to get covered with dust. On investigating the matter, he found that in the case of the dusty cords the switch controlling those lights was on the negative side, and thus the cords were always at the pressure of the positive main whether the lights were on or not. The clean cords had the switch fixed on the positive side, as shown in Fig. 1. One may argue that if the negative main is not earthed, why should it not attract dust. The phenomenon is due to the fact that the negative main

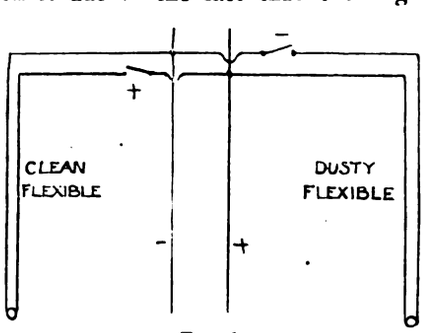

FIG. 1.

always tends to earth itself. A test on the Westminster Company's system showed the negative to be 30 volts below earth potential and the positive to be 170 volts above earth, so naturally a positively charged conductor would have a much greater attraction for dust than a negative one. To test the attractive effect of the positive 'bus bar in a station, take a glass plate thickly covered with dust, hold it immediately below the 'bus bar, and tap it smartly. The particles of dust will be seen to fly up and stick to the 'bus bar. The effect is very noticeable in a 500-volt traction station.

Now, to consider the fact of the dust collecting on glass or slate surfaces close to live conductors. On withdrawing a slate from the side of a positive switch in a Ferranti cell type traction switchboard, the dust will be noticed to have collected as shown in Fig. 2, the outline of the switch being shown dotted. At those points where the portions of the switch approach closest to the slate, the dust will be found the thickest. Considering Fig. 3, A being switch and B being piece of slate or glass. When the switch is not closed, both the switch and slate will be of neutral potential. On closing the switch it will be charged positively, and any dust floating about will be attracted to and adhere to the metal parts of the switch. Not only so, but there will be

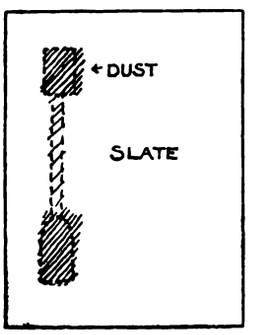

FIG. 2.

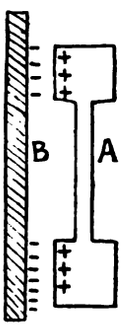

FIG. 3.

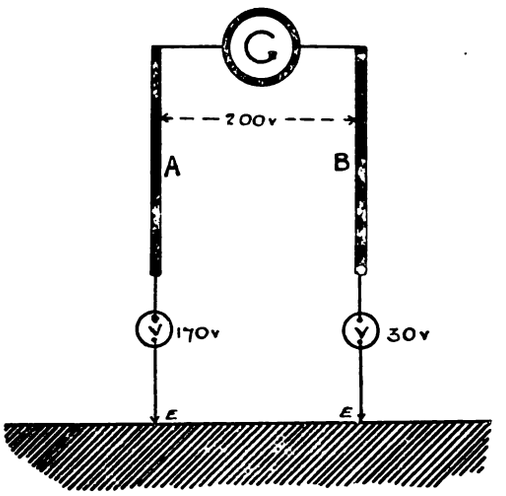
an induced charge of negative electricity on the surface of the slate closest to the switch. These portions of the slate that are charged will also attract the dust floating about, and a coating of dust will be formed as shown in Fig. 2. I have noticed a long string of dust particles attached to the switch stretching out horizontally to the slate. On removing the slate the particles fell down by the side of the switch, but on reinserting the slate panel they again assumed an horizontal position, showing that they were attracted by the negative charge on the slate.—W. A. T.

*Answer to No.* 785 (*awarded* 7*s.* 6*d.*).—The phenomenon which has been observed by "H. G. H." is by no means an uncommon one, yet it is a peculiar one, inasmuch that it has not been observed in connection with alternating-current supply systems, but only with those systems supplying continuous-current energy. The ultimate effects are really due to an electrostatic action, which, however, is brought into existence by peculiar conditions invariably present on



*all* continuous-current systems. The electrostatic action is one of attraction.

In the accompanying figure, suppose that A and B represent the positive and negative 'bus bars respectively of a central-station switchboard working on the ordinary two-wire system, also suppose that the voltage of supply is, for the purpose of providing a concrete example, 200 volts. Then the difference of potential between A and B will be 200 volts. If, however, an electrostatic voltmeter, say of the multicellular or similar type, is connected between the positive bar and the earth, as shown in the figure, it will be found that there is an indication of a difference of potential between that bar and the earth of approximately

Digitized by Google

170 volts. Whilst, on the other hand, if the negative bar is served in precisely the same manner, then the voltmeter will indicate only 30 volts approximately. This shows that the potential of the negative bar is (170 – 30), or 140 volts nearer the potential of the earth than the potential of the positive bar is.

Now, the real action is this: The particles of dust, containing probably minute pieces of metal, mineral, etc., are at the potential of the earth because they are in contact therewith. The potential of the positive bar is 170 volts higher than this potential, and the consequence is that an electrostatic action in the form of attraction is set up between the bar and the particles of dust. The amount of attraction is proportional to the square of 170—namely, 28,900. Hence, an amount of dust proportional to this number collects on the positive bar. Attraction, of course, is set up between the negative bar and the particles of dust, but in this case the phenomenon is not so pronounced as in the previous case, because the amount of dust which collects on the negative bar is proportional to the square of 30, or 900. It is clear, from the foregoing, that there is practically 300 times as much dust attracted to the positive bar as there is to the negative, consequently, whilst a little may settle on the latter, it is almost imperceptible, and, certainly, it is incomparable with that which settles on the positive bar.

The phenomenon of dust collecting on the glass panes is really an extension of the above. The glass, being in the vicinity of the bars, is electrified by electrostatic induction, its potential, however, being opposite in sign to that of the bar electrifying it. The ultimate result is then precisely the same as with the bars, so far as external observation can detect. Because, since the pane opposite the positive bar will be more highly electrified than the pane opposite the negative bar, the former pane will attract the particles of dust more strongly than the latter.—G. W. BURLEY.

*Answer to No.* 785 (*awarded* 5*s.*).—The collection of dust on the positive 'bus bar is due to the electrostatic action of the 'bus bar on the particles of dust floating near. Each dust particle may be considered as an insulated conductor floating in the electric field set up by the positive 'bus bar. The dust then by cutting the lines of force acquires equal and opposite electrification at different parts of its surface, that part becoming positive which is presented to the negative boundary of the lines of force and *vice versâ*. Having been electrified by induction, the dust then obeys the well-known law of static electricity—namely, "that electrified bodies of like polarity repel each other, and those of unlike polarity attract each other. Thus, as each particle of dust comes within the active sphere of the positive bar it is electrified by induction, and its negative pole is attracted towards the positive 'bus bar, hence the abnormal collection of dust. The collection of dust on the window opposite the positive bar is due to the same inductive action. The particles of glass are electrified with their negative poles facing the positive bar, and so the positive poles of the dust are attracted towards the glass. The negative 'bus bar being at the same potential as the air around it has no inductive action on the dust or the glass opposite it, hence there is only a normal amount of dust on either.—B.

*Question No.* 786.—At a hydro-electric installation some surplus power is available. State the best method of obtaining a record of the same with a view to installing another turbine 12 months hence. Fall, 11ft., subject to frequent floods.

*Best Answer to No.* 786 (*awarded* 10*s.*).—In dealing with problems concerning water power, it is necessary to have full particulars of conditions before any definite opinion can be formed as to what might or should be done. Unfortunately, "A. R." does not give that, but only informs us that he has a head of 11ft., and has frequent floods. With a low fall it is quite common in England for flood rivers to reduce the available head considerably, owing to the tail water rising more than the head water. If there is a sharp bend or a narrow channel further down stream near the turbine-house, it is quite common for the tail water to rise several feet, while at the same time the water in the head race has only risen as many inches, so that "A. R." will need to ascertain to what extent this is likely to affect him, as the power available is not in proportion to the increased discharge of water. With only 11ft. head, each horse-power will need about 70 cubic feet of water per minute. We are not told to what extent his power is already developed, but it is clear, if he is using a fair amount of power, that the quantity of water to measure is beyond the capacity of the usual notched board method, and methods suitable for measuring much larger quantities must be used. If the head weir is in good repair, fairly wide, and level, it would be very useful for measuring the water, providing the whole of the water can be passed over it. To do this, drive a stake into the river near the bank, about 7ft. or 8ft. upstream from the weir, so that the top of the stake is level with the top of the weir. Now stop all water from going through the turbines by closing the hatches, and after the water has finished rising, measure the depth of water above the top of the stake, and, having previously measured the width of the weir, use the weir formula,

$$Q = 200\, l\, \sqrt{h^3},$$

Q being the quantity of water in cubic feet per minute, $l$ the length of the weir in feet, and $h$ the depth of water in feet or portion of a foot. If he measures the quantity of water in this way, say, once a week, or whenever he sees any appreciable change in the height of the river-level, he will get a record of quantities quite accurate enough, but when measuring the quantity he should the same day measure the difference in the levels of the head and tail waters, commonly called the head or fall. Having the quantity and head, he can calculate its power by

$$P = \cdot 001892\ Q\ H,$$

P being the theoretical horse-power, Q the cubic feet of water, and H the head in feet. The actual horse-power available for driving, after allowing for power lost on the bevel gears and belting, would range from 63 per cent. (for the cheaper types) to 70 per cent. (for the best English or Swiss makes) of the theoretical power.

If the head weir does not pass all the water, or is in bad repair, or through other causes not suitable for using for measurements, it is quite possible that somewhere in the neighbourhood of his installation "A. R." can find a length of the stream where the section is approximately constant for from 50ft. to 150ft. in length; then find the section by multiplying the width by the average depth; by taking several sections in the chosen length and determining the average section a nearer approach to accuracy is obtainable. Drive two stakes in this portion of the river a given distance from one another. Then almost fill an empty bottle that has a long neck with water so that only an inch or two of neck projects above water when put in the river. Throw this float in the river a little above the first stake and note the time (in seconds) which it takes to pass from one stake to the other; repeat several times, and take the average time. The quantity of water, Q, will then easily be found by multiplying the area of the stream by the measured length between stakes (both measurements in feet) and also by 60 and dividing the product by the time in seconds. From this result deduct 15 to 20 per cent. for side and bottom friction. This method gives a lot more trouble, as any difference in the discharge of the river alters the width and depth, and getting the average section for each difference in levels gives a lot of work.

Now, having obtained the data as to horse-power available and deducting horse-power in use he will arrive at horse-power now running to waste. This running to waste is possibly taking two courses. First, over the weir and down the by-pass. Second, if "A. R." was not careful in selecting his existing turbines, it is quite possible there is quite an appreciable loss of water there owing to their inefficiency. It then turns to the problem as to whether in the end (if his present turbine is wasteful), if it would be cheapest to instal another small turbine, or to take out his present machine and instal a more powerful one of a better type. If "A. R." has had but limited experience in this matter he has a difficult problem to solve, and I would advise him to get full data as to quantity and head of water and get in communication with one or two of the best turbine builders, who would be pleased to put their services at his command, and being experts would be less likely to slip up.—K.

*Answer to No.* 786 (*awarded* 7*s.* 6*d.*).—The best way to find the amount of surplus power would be to find the total power of the stream, and compare the resultant figure with the horse-power already used; so we have first to measure the total flow or total quantity of water, and then convert this into mechanical and electrical horse-power to get what is required. There are two good ways to measure this total quantity.

*A.* In large streams it is done by finding the average cross-section of the stream for some distance along its length, say for 50 yards, and then measuring the velocity of water over that same distance by a water-meter. If an instrument is not available, it can be found by noting the velocity of a piece of wood in mid-stream with a marked distance and a reliable stop-watch. Take several readings to get good reliable average figures. Then if V = velocity of "wood" in feet per second, and $v$ mean velocity of the stream in feet per second, then

$$v = V \times \frac{7\cdot71 + V}{10\cdot28 + V} \text{ approximately.}$$

If A = sectional area in square feet;
Q = total quantity of water in cubic feet per second.

Then $$Q = A\,v \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

*B* If the stream be small, as the large majority of streams in England are, a temporary weir may be made

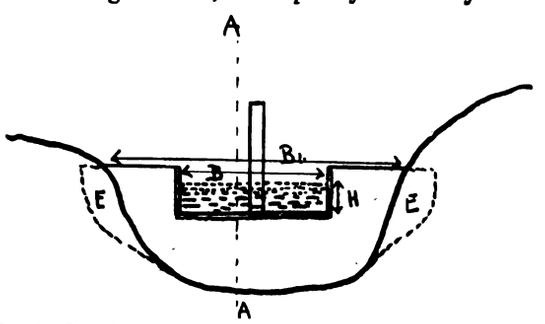

FIG. 1.—Cross Section. E = Edges of Weir Board Sticking into Bank.

and placed across the stream, so that the whole of the water passing down the stream will have to pass over a notch cut into this weir. Make up a large board big enough for the stream; the thickness must be large enough to stand the water pressure. This is, of course, a very variable quantity, and the details must be left to the engineer at this particular station. It is a good plan to slot the banks of the stream a little to take the extreme edges of this board. This will help to hold it firmly in place. On the top of the board, in the middle, a notch must be cut (see Fig. 1). This notch may be any width from one-fourth to total width of stream. Do not make it less than one-fourth. It must also be arranged so that there is not less than 6in. of water above the bottom of notch. That is the distance H (Fig. 1). The sides and bottom of the notch must be chamfered to a fine edge to get the best results, the chamfer being on the down-stream side. When the board is in its place in river, it becomes necessary to adopt

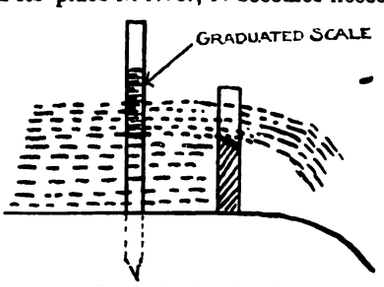

FIG. 2.—Section through A A.

some scheme to measure the distance H, as it may vary during the test, and also it is very important to measure it accurately. The best way is to drive a stake into the bed of river, some little way above the board where the water is comparatively still. This stake should be graduated over a large part of its length into feet and inches, and must be so fixed that the bottom of the graduated part, the zero of the scale, is on a level with the bottom of the notch (Fig. 2). This is done by driving the stake into water a little way, and then adjusting it as the water rises to the level of notch. When the water is just as high as the bottom of notch, the zero should be at water-level. Everything is now ready for taking observations.

Let H = height of water over notch in inches;
$H_1$ = " " " in feet;
B = breadth of notch in feet;
$B_1$ = " stream " ;
Q = total quantity of water in cubic feet per minute;
W = " " pounds "

We have the choice of several formulæ for calculation of Q or W. All are good, and agree well in practical working.

$$Q = 321\,H_1\,K\,B\,\sqrt{H_1} \quad . \quad . \quad . \quad . \quad (2)$$

Here we have a constant K which is $\cdot57 + \frac{B}{B_1}$ for all values of $\frac{B}{B_1}$ between one-fourth and unity.

$$Q = 321\,K\,B\,\sqrt{H_1^3} \quad . \quad . \quad . \quad . \quad (3)$$

$$Q = 7\cdot72\,K\,B\,\sqrt{H^3} \quad . \quad . \quad . \quad . \quad (4)$$

$$W = 482\,K\,B\,\sqrt{H^3} \quad . \quad . \quad . \quad . \quad (5)$$

Here constant K depends also on ratio of $\frac{B}{B_1}$. Exhaustive figures have settled the value of K as below:

| $\frac{B}{B^1}$ = | 1·0 | ·9 | ·8 | ·7 | ·6 | ·5 | ·4 | ·3 | ·25 |
|---|---|---|---|---|---|---|---|---|---|
| K = | ·667 | ·66 | ·65 | ·64 | ·63 | ·62 | ·61 | ·6 | ·595 |

If the notch is made half width of the stream—that is, $\frac{B}{B_1} = \cdot5$—then

$$Q = 4\cdot8\,B\sqrt{H^3} = 199\,B\sqrt{H_1^3} \quad . \quad . \quad (6)$$

Another formula used with this method is

$$Q = 40\,K\,(B - \cdot2\,H_1)\,H_1\sqrt{2\,g\,H_1} \quad . \quad . \quad (7)$$

The author specifies that the ratio $\frac{B}{B_1}$ should not be less than $\frac{1}{3}$, and also gives K as a constant = 62·2 for all values above this limit to unity.

Sometimes it is impossible to avoid having rather a high velocity of water as it approaches the board. If this velocity is too large to neglect, a slight modification is necessary. If V = this velocity in feet per second and $H_0$ the head due to it, then

$$H_0 = \frac{V^2}{2\,g};$$

and equation (3) becomes

$$Q = 321\,K\,B\,\{\sqrt{(H_1 + H_0)^3} - \sqrt{H_0^3}\} \quad . \quad (8)$$

Unless the velocity is really high this makes very little difference to result. If only an approximation is wanted, it can easily be neglected altogether. Only on one occasion have I known any appreciable difference in result of calculations to be caused by this water velocity before the board. That was on a small but rather rapid stream in a small village of Suffolk, where a turbine was being installed to run a dynamo for house lighting.

We have now obtained either our total quantity of water in cubic feet per minute, or total weight of water in pounds per minute for equation (5).

Let W.H.P. = total water horse-power;
Q = total quantity of water cubic feet per minute;
G = weight of cubic feet of water = 62·4lb.
H = head in feet;
W = total quantity of water pounds per minute.

Then $$\text{W.H.P.} = \frac{Q \times G \times H}{33{,}000} \quad . \quad . \quad . \quad . \quad (9)$$

$$\text{W.H.P.} = \frac{W \times H}{33{,}000} \quad . \quad . \quad . \quad . \quad . \quad (10)$$

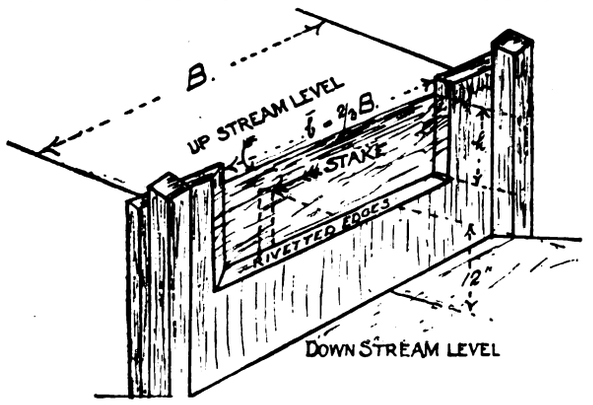
From this the amount of power available can be calculated: first, by subtracting the W.H.P. already being used; secondly, by allowing for turbine efficiency, varying from 70 to 90 per cent. with different makes and sizes, we get the mechanical horse-power available from the surplus. Now, allowing for the efficiency of the elec-

Digitized by Google

trical generator 85 to 95 per cent., according to kilowatt output, the exact figure for horse-power available still from the river for lighting or power supply will be obtained.

These tests should be taken with river in normal state, and the resultant figure used as a minimum basis, the frequent flooding will not then adversely affect the calculations.—F. R.

*Answer to No.* 786 (*awarded* 7*s.* 6*d.*).—Where the fall is only 11ft., and where the source of the water supply is liable to floods, a pressure turbine, arranged to work entirely immersed in the tail water if necessary, and provided with a suction pipe at its discharge, to take full advantage of the complete head during occasions of drought and a consequently diminished water-level at the tail race, would be the most efficient motor. In all probability the existing plant is of this description, hence it will be impossible to measure the water passing through these turbines at the tail race, resort having to be made to the watercourse. It is necessary that the quantity of water being used in the existing installation should be measured together with the water passing unused over the weir—if such exists—immediately below the intake; due note also being taken of the spill or overflow water at the turbine end of the watercourse, where a head tank is frequently employed joined up to the line of piping.



The means employed for measuring such quantities of water may be gleaned from the accompanying sketch and explanation. Place a board in a position where the water flows gently. Cut a notch in the board of sufficient depth to pass all the water to be measured, and not more than two-thirds of the width of the channel. The bottom edge of the notch should be level, and this edge, together with the sides, should be bevelled to almost a sharp edge towards the down-channel side, as shown, and the surface of the water, below the notch, should not be more than 12in. About 3ft. behind the notch drive a stake into the bottom of the channel, the top of the stake being level with the notch. When the water has reached its greatest depth measure the distance marked *h* in the sketch—from top of stake to surface—with a thin-edged rule; this will give the depth of water flowing. From the table given herewith, or from others found in most books of formulæ, the quantity of water in cubic feet per minute for varied depths of weirs can be readily worked out. The number in the table corresponding to the depth, *h*, when multiplied by the length of the notch in inches will give the quantity of water in cubic feet per minute.

| Depth of weir, *h*, in inches. | Multiplier. | Depth of weir, *h*, in inches. | Multiplier. |
|---|---|---|---|
| 1 | ·40 | 9 | 10·85 |
| 2 | 1·14 | 10 | 12·71 |
| 3 | 2·09 | 11 | 14·67 |
| 4 | 3·22 | 12 | 16·73 |
| 5 | 4·50 | 13 | 18·87 |
| 6 | 5·90 | 14 | 21·09 |
| 7 | 7·44 | 15 | 23·38 |
| 8 | 9·10 | 16 | 25·76 |

Taking an example of this method of calculation. If the depth, *h*, of water in the notch be 8in, and the length, *b* 60in., the multiplier given in the foregoing table corresponding to 8 is 9·10. Then we have 9·1 × 60 = 546·0 cubic feet per minute. Both in the watercourse and in the main stream below the intake, or at the weir, notch-boards as described might be placed, and also at the overflow or spill a similar method may be employed if the overflow edge is not level or is irregular. Should a concrete weir already exist in a stream of medium dimensions, by the application of substantial timbers, arranged in a manner akin to that of the notch-board in sketch, reliable results may be obtained. Readings of the measurements at the notch-boards, taken say twice each day and duly logged, when studied together at the year's end will provide the necessary data from which the surplus power in the stream not utilised is easily reckoned. The reason why separate records are taken of the volume of water passing along the watercourse to energise the existing turbines is to provide reliable figures, giving the water power used in producing the year's output in Board of Trade units, these latter, of course, having been carefully compiled.

In conjunction with these readings and measurements there should be tabulated simultaneously, during the year, the rainfall within the catchment area whence the stream draws its supply. A comparison of the total year's rainfall with previous annual results will determine whether the quantity of rain which has fallen throughout the year's test has been normal or otherwise. Some advantage would accrue from the use of more than one rain-gauge placed in different parts of the catchment area. This would obviate any error due to local showers being taken as general or common to the district.

It may be that a large river is involved in these calculations; if such be the case, then another method other than that of the notch-board may be more satisfactory, in which is eliminated all measurements of the water utilised in the existing plant, though this should still be done if convenient. By taking the total volume of water flowing in the river above the intake for the watercourse, the total power available is ascertained; deducting from this the capacity of existing plant, the surplus power is the resultant. This second method is as under: Choose a length of river about 50ft. to 100ft. in length, along which the water flows gently, and where the section of the river bed is reasonably uniform; find its area by multiplying the average width by the average depth, several sections on the chosen length being measured to find the mean dimensions. Two stakes should be fixed in the river some known distance apart; a float thrown in above the first stake should be timed from the moment it passes the first until it reaches the second stake. Repeat this several times to secure an average rate of flow, and from these figures the quantity of water passing in cubic feet per minute can be found by multiplying the average sectional area of the river by the measured length in feet, then again by 60, and dividing the product by the time in seconds taken by the float to pass over the chosen length from the first to the second stake. For instance, the sectional area of a river is 80 square feet, and the float passes over the measured length of 100ft. in 80 seconds, then $\frac{80 \times 100 \times 60}{80}$ = 6,000 cubic feet per minute. From this result nearly 20 per cent. must be deducted to allow for the friction on the banks and river bottom. Then 6,000 − 1,200 = 4,800 cubic feet per minute. A simple calculation at the end of the year's test from the accumulated figures will give the available water power now going to waste, and also whether any advantage would ensue from the construction of a storage dam. Assuming the average surplus water passing over the river to be 5,000 cubic feet per minute, this volume, with 11ft. as the available head, provides the following equation:

$$\frac{5{,}000 \times 62{\cdot}5 \times 11 \times {\cdot}75}{33{,}000} = \text{horse-power} = 78{\cdot}125 \text{ h p}$$

This equation will be correct for all turbines or other water motors of 75 per cent. efficiency.

In working out available water power it is not a reliable policy to allow for the full head of water in the suction pipe of a pressure turbine; about ·5 of the head due to this would be a safe estimate.—WALLSEND ON TYNE.

[Other replies to Question No. 786 will be given in our next issue.—ED. *E. E.*]

# CLASSIFIED DIRECTORY OF ELECTRICAL TRADES.

### Accumulators.

British Accumulator Co., Ltd., 15, Victoria-street, London, S.W.
Electrical Power Storage Co., 4, Great Winchester-street, E.C. [Stratford.
Hart Accumulator Company, Marshgate-lane,
Johnson and Phillips, Old Charlton, Kent.
Tudor Accumulator Co., Limited, 16, Victoria-street, S.W.

### Accumulator Acid Manufacturers.

Berk, F. W., and Co., Limited, 1, Fenchurch-avenue, London, E.C.

### Address Label Makers.

Endolithic Manufacturing Co., 61½, Fore-st., E.C

### Arc Lamp Hoists.

Abbott and Co., Newark-on-Trent.

### Arc Lamps.

British Thomson-Houston Company, Rugby.
Brockie-Pell Arc Lamp, Limited, 60, Worship-street, London, E.C.
Crompton and Co., Chelmsford.
Defries, J., and Sons, 146 and 147, Houndsditch, London, E.C.
Electrical Company, Limited, 121-125, Charing Cross-road, S.W.
Foster and Co., Worple-road, Wimbledon.
General Electric Co., 71, Queen Victoria-street.
India Rubber, etc., Co., 106, Cannon-st., E.C.
Johnson and Phillips, Old Charlton, Kent.
Newton Electrical Works, Taunton.
Union Electric Co., 151, Queen Victoria-st., E.C

### Batteries (Primary) and Accessories.

General Electric Co., 71, Queen Victoria-street.
India Rubber, etc., Co., 106, Cannon-st., E.C.
Johnson and Phillips, Old Charlton.

### Belting.

Cort, A., and Co., Camberwell, London, S.E.
Hendry, J., 252, Main-st., Bridgeton, Glasgow.
Webb and Son, Combs Tannery, Stowmarket.
Willcox and Co., 36, Southwark-street, S.E.

### Bitumen Refiners.

Carr, R., and Co., 6 & 8, Lime-st. Square, E.C
Keys, W. H., Hall End Works, West Bromwich

### Boilermakers.

Babcock and Wilcox, 30, Farringdon-st., E.C.
Davey, Paxman, and Co., Colchester.
Galloways Limited, Manchester.
Hindley, E. S., and Sons, 11, Queen Victoria-street, London, E.C.
Ransomes, Sims, and Jefferies, Ipswich.

### Cable and Wire-Covering Machinery.

Bridge, D., and Co., Castleton, Manchester.
India Rubber, etc., Co., 106, Cannon-st., E.C.
Johnson and Phillips, Old Charlton, Kent.

### Cable and Wire Makers.

Anchor Cable Company, Leigh, Lancs.
British Insulated and Helsby Cables, Limited, Prescot.
Callender's Company, Hamilton House, Victoria-embankment, E.C.
Electrical Co., 121-125, Charing Cross-road.
Garnett, W. T., and Co., Barkerend Mills, Bradford.
General Electric Co., 71, Queen Victoria-st., E.C
Henley's, W. T., Telegraph Works Company, Blomfield-street, London-wall, E.C.
India Rubber, etc., Co., 106, Cannon-st., E.C.
Johnson and Phillips, Old Charlton, Kent.
London Electric Wire Co., Playhouse-yd., E.C.
St. Helens Cable Co., Limited, Warrington.
Western Electric Company, Bridge-chambers, 171, Queen Victoria-street, E.C.

### Carbons (Arc Light).

Crompton and Co., Arc Works, Chelmsford.
Electrical Co., 122, Charing Cross-road, W.C.
General Electric Company, 69, 71, and 88, Queen Victoria-street, E.C.
India Rubber, etc., Co., Silvertown, Essex.
Johnson and Phillips, Old Charlton, Kent.

### Castings and Cleats.

General Electric Company, 71, Queen Victoria-street, E.C.
Haden, G. N., Trowbridge.
Kuettner, B., and Macdonell, 3, Adam-street, Adelphi, W.C.
Lowcock, A., Coleham Foundry, Shrewsbury.
Simplex Steel Conduit Co., Coventry-street Birmingham

### Dynamo Oil.

Willcox and Co., Southwark-street, S.E.

### Dynamos, Transformers, Motors, etc.

Allen, W. H., Son, and Co., Queen's Engineering Works, Bedford.
British Thomson-Houston Company, Rugby.
British Westinghouse Electric and Mfg. Co. Westinghouse Building, Norfolk-st., W.C.
Crompton and Co., Chelmsford.
Electric Construction Company, Dashwood House, New Broad-street, E.C.
Electrical Co., 121-125, Charing Cross-road.
Electromotors Limited, Openshaw, Manchester
Ferranti Limited, Hollinwood, Lancs.
General Electric Co., 71, Queen Victoria-street
India Rubber, etc., Company, Silvertown
Industrial Engineering Co., Hyde, Manchester
Johnson and Phillips, Old Charlton, Kent.
Lahmeyer Electrical Co., Limited, 109-111, New Oxford-street W.C.
Newton's Limited, Taunton.
Peebles, D. B., and Co., Edinburgh
Union Electric Co., 151, Queen Victoria-st., E.C

### Ebonite and Vulcanite.

Traun, Dr. Heinr., and Sons, 8, Redcross-street, London, E.C.

### Electric Cooking Apparatus.

Crompton and Co., Salisbury House, London wall, E.C.
General Electric Co., 71, Queen Victoria-street.

### Elevating, Conveying Plant, Cranes, etc

Crompton and Co., Chelmsford.
Electrical Co., 122, Charing Cross-road, W.C
General Electric Co., 71, Queen Victoria-st., E.C
Graham, Morton & Co., Ld., Hunslet, Leeds
Lahmeyer Electrical Co., Limited, 109-111 New Oxford-street, W.C.

## Electrical Engineers *(continued)*—

Greig, L. P., Electricity Works, Bury Edmunds.
Grigg, W., 33, Eastbourne-terrace, Hyde Park
Grimsdale, W. H., 8, Queen Anne's-gate, S.W.
Hadfield, J. W., Corporation Electricity Works, Barnstaple.
Hall, W. H., Electricity Works, Morcambe.
Harrison, H., Dublin and Lucan Electric Railway, Dublin.
Harrison, H. E., 28, Sussex-place, Regent's Park
Harris, W. A., Port of Spain, Trinidad, British West Indies.
Haskew, Fred, and Co., Enville-street Works, Stourbridge.
Haslam, A. P., 81, St. Dunstan's-road, Hammersmith, S.W.
Hawkins, C. C., 37, Conduit-road, Bedford.
Heaviside, A., 12, Tring-avenue, Ealing, W.
Heenan, W. E. J., Electricity Works, Southend-on-Sea.
Hemingway, C. A., 10, Petersham-road, Richmond.
Henry, M. B., Electricity Works, Radcliffe.
Hewlett, E. H., Electricity Department, Mansfield Corporation.
Hickley, H. N., Newton Works, Taunton
Hoadley, E. E., Electricity Works, Maidstone
Hockley, N., Brighton Corporation Electricity Works, North-road, Brighton.
Holliday, S. B., Corpton. Tramways, Brighton
Hollingworth, E. M., Electricity Works, St. Helens
Hooper, P. N., Electricity Works, Poplar.
Hopkins, A. & W., Olun House, Surrey-st., W.C.
Hopkinson, Dr., E., Salford Ironworks, Manchester.
Ingram, E. L., Electricity Works, Bournemouth.
Ireland, T., Great Northern Railway, Retford.
Jackson, G. H., Electricity Works, Northampton
Jeckell, J. A., Electric Light Station, Coventry.
Jenkins, T. A., Heolgerrig, Merthyr Tydfil.
Jenkinson, B. H., 9, Gray's Inn-square, W.C., and 18, Crouch Hall-road, N.
Johnson and Phillips, 14, Union-court, Old Broad-street, E.C.
Johnson, W. C., The Dignaries, Westcombe-park, Blackheath, S.E.
Johnston, C. M., Corporation Electricity Works, Shrewsbury.
Joyce, S., Altrincham Electric Light Station.
Kelvin, Lord, Glasgow.
Kempe, H. R., General Post Office, E.C.
Kilgour, H., Electric Light Station, Cheltenham.
Kimmins, P. J., Electricity Works, Lynmouth, Barnstaple, N. Devon.
King and Co., Prince Regent-street, Leith.
Knight, J. D., Electricity Works, Ealing, W.
Knight, W. L., Electricity Works, Aberystwyth
Knowles, C. E., Electricity Works, Glossop.
Lacey, F. W., Tramway Offices, Bournemouth.
Lackie, Wm., 75, Waterloo-street, Glasgow.
Lambe, J. M., Electricity Department, Town Hall, Kimberley.
Lambert, Jno., Corporation Electricity Works, Perth.
Lee, H. T., Electricity Works, Wimbledon.
Le Bagot, John, 64, Market-street, St. Andrews, N.B.
Le Feuvre, W. T., Electricity Works, Bexhill.
Lewis, F. H., Electricity Works, Leyton.
Long, E. D., Electricity Works, Grays Thurrock
Lorrain, J. G., Norfolk House, Norfolk-street, W.C.
Lucas, Owen, and Pyke, Albany-buildings, 39, Victoria-street, S.W.
Lundberg, A. P., Pioneer Electrical Works, 477 to 487, Liverpool-road, London, N.
Lunn, J. R. P., Corpton. Tramways, Darlington
Maclean, M., Glasgow and West of Scotland Technical College, Glasgow.
Macmuldrow, W. G. P., Central Electric Lighting Station, Claremont, Sonth Africa.
Macrory, R. V., Londonderry Corporation.
Marsh, J. A. T., Electricity Works, Dudley.
Marshall, A. W., 180, Loughborough-road, Brixton
Marshall, R., Electricity Works, Ayr.
Maquay, G. A., Electricity Works, Pontypool.
Mather, T., City and Guilds of London Institute, Exhibition-road, S.W.
Mather and Platt, Salford, Manchester.
Maurice, W., Hucknall Torkard Collieries, Notts.
Maxwell, H. B., Electricity Works, Partick
Mayson, C. M., Charing Cross and Strand Supply Corporation, 15 Maiden-lane, W.C.
McCarter, R. D., Electric Tramways, Bath.
M'Cowan, V. A. H., Town Hall, Belfast.
McHaffie, H. S., Electricity Supply Works, Hoylake, Cheshire.
McLean, J. Hardie, Midland Electric Corporation, 73, Lichfield-street, Wolverhampton.
McMahon, J., Blackpool and Fleetwood Tramroad Company, Bispham, near Blackpool.
Meade, R. E., Electricity Works, Stafford.
Midgeley, C. A., Electricity Works, York
Milton, C. D., Electricity Works, Maidenhead
Mitchell, J. B., Electricity Works, Woolwich
Monson, P., Town Hall, Kensington.
Moulton, J. F., 11, Queen's Bench-walk, E.C.
Mountain, A. B., Borough Electrical Engineer, Huddersfield.
Mountain, W. C., Close Works, Newcastle-on-Tyne.
Munro, H. D., Exeter Corporation.
Murray, E. T. Ruthven, Willesden District Council, N.W.
Nalder, F. H., 34, Queen-street, E.C.
